Acceleration is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: *Accelerator* mode and the *Rapid Accelerator* mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.

The Accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. The Accelerator mode supports the Simulink debugger and profiler. These tools assist in debugging and determining relative performance of various parts of your model. For more information, see "Run Accelerator Mode with the Simulink Debugger" on page 32-32 and "How Profiler Captures Performance Data" on page 28-5.

The Rapid Accelerator mode works with only those models containing blocks that support code generation of a standalone executable. For this reason, Rapid Accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than the Accelerator mode. When used with dual-core processors, the Rapid Accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the Accelerator and Rapid Accelerator modes, and how to measure the difference in performance, see "Comparing Performance" on page 32-34.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see "Automated Performance Optimization".

To manually employ modeling techniques that help achieve faster simulation, see "Manual Performance Optimization".

How Acceleration Modes Work

In this section...
“Overview” on page 32-4
“Normal Mode” on page 32-4
“Accelerator Mode” on page 32-5
“Rapid Accelerator Mode” on page 32-6

Overview

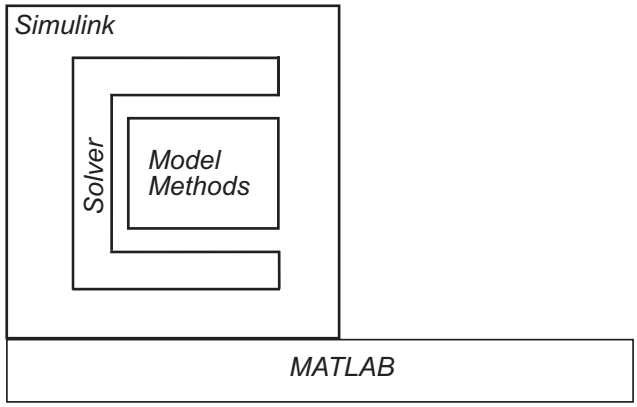
The Accelerator and Rapid Accelerator modes use portions of the Simulink Coder product to create an executable. These modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

Note: The code generated by the Accelerator and Rapid Accelerator modes is suitable only for speeding the simulation of your model. You must use the Simulink Coder product if you want to generate code for other purposes.

Normal Mode

In Normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. “Model Methods” on page 3-16 include such things as computation of model outputs. Normal mode runs in one process.



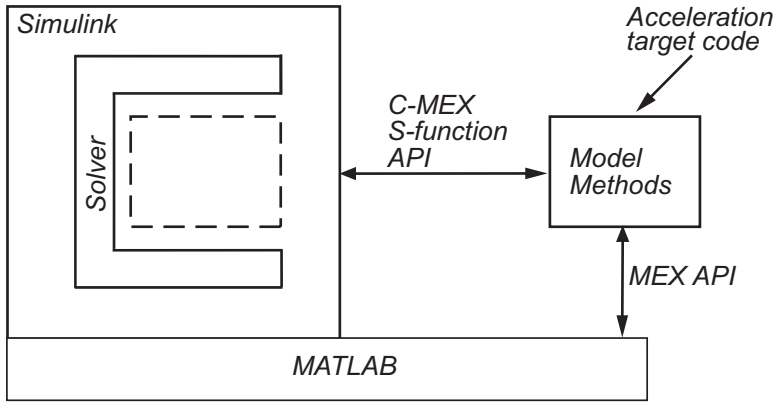
One Process

Accelerator Mode

The Accelerator mode generates and links code into a C-MEX S-function. Simulink uses this *acceleration target code* to perform the simulation, and the code remains available for use in later simulations.

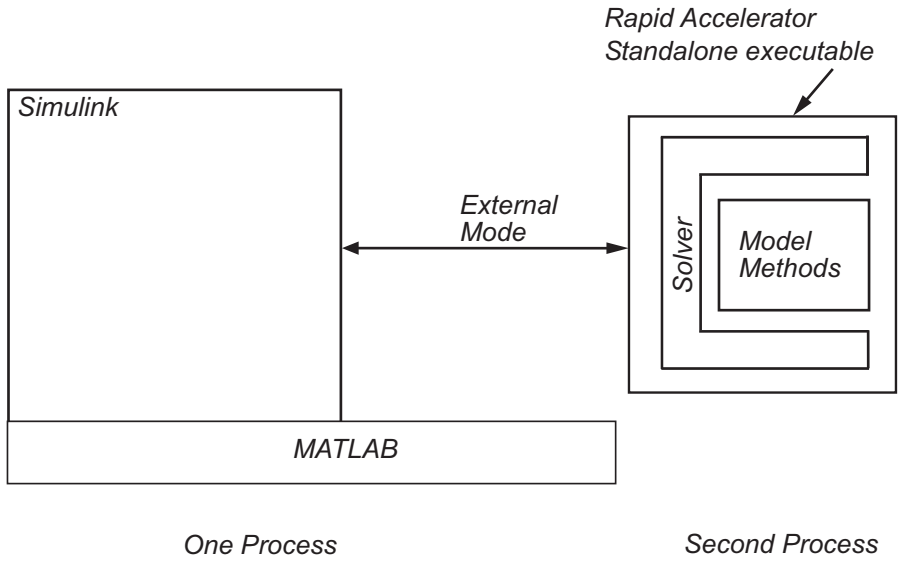
Simulink checks that the acceleration target code is up to date before reusing it. As explained in “Code Regeneration in Accelerated Models” on page 32-8, the target code regenerates if it is not up to date.

In Accelerator mode, the model methods are separate from the Simulink software and are part of the Acceleration target code. A C-MEX S-function API communicates with the Simulink software, and a MEX API communicates with MATLAB. The target code executes in the same process as MATLAB and Simulink.



Rapid Accelerator Mode

The Rapid Accelerator mode creates a *Rapid Accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses External mode (see "External Mode Communication") to communicate with Simulink.



MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

Code Regeneration in Accelerated Models

In this section...
"Determine If the Simulation Will Rebuild" on page 32-8
"Parameter Tuning in Rapid Accelerator Mode" on page 32-8

Changing the structure of your model causes the Rapid Accelerator mode to regenerate the standalone executable, and for the Accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

Determine If the Simulation Will Rebuild

The Accelerator and Rapid Accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

1. Use the `Simulink.BlockDiagram.getChecksum` command to obtain the checksum for your model. For example:

   ```
   cs1 = Simulink.BlockDiagram.getChecksum('myModel');
   ```

2. Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
3. Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see the example model `slAccelDemoWhyRebuild`.

Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, Rapid Accelerator Mode handles block diagram and runtime parameters differently from other parameters.

Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` command or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	

Loading and Logging Parameters		
ConsistencyChecking	MaxConsecutiveZCsMsg	SaveOutput
Decimation	MaxDataPoints	SaveState
FinalStateName	MinStepSizeMsg	SaveTime
InitialState	OutputOption	StateSaveName
LimitDataPoints	OutputSaveName	TimeSaveName
LoadExternalInput	SaveFinalState	
LoadInitialState	SaveFormat	

Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in Rapid Accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

1. Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
2. To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
3. To specify the modified parameters to the `sim` command, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

For more information, see “sim in parfor with Rapid Accelerator Mode” on page 24-19.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes:	Passed Directly to `sim` command	Passed Graphically via Block Diagram or via `set_param` command
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

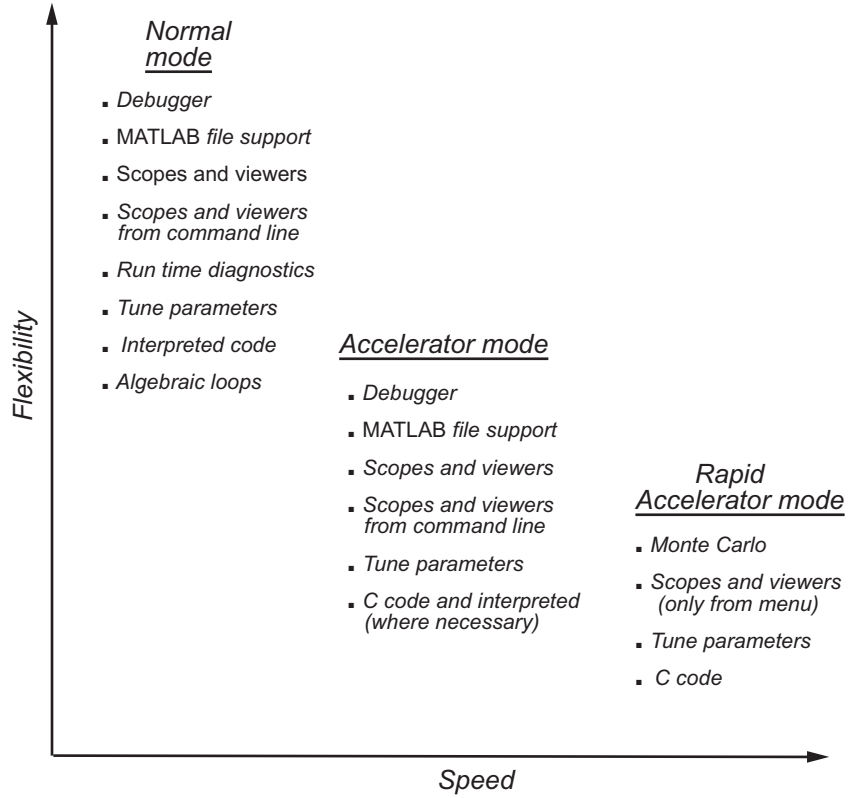
Choosing a Simulation Mode

In this section...
"Simulation Mode Tradeoffs" on page 32-11
"Comparing Modes" on page 32-12
"Decision Tree" on page 32-14

Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either Accelerator mode or Rapid Accelerator mode instead of Normal mode.



Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between Normal and Rapid Accelerator modes in performance and in interaction with your model. If your model has 3-D signals, use Normal or Accelerator mode. Accelerator mode does not support runtime diagnostics.

Rapid Accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code is available for all of the blocks in the model. In addition, Rapid Accelerator mode does not support 3-D parameters and sinks.

Note: An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in Normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in Normal mode.

Tip To gain additional flexibility, consider using model referencing to componentize your model. If the top-level model uses Normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Referenced Model Simulation Modes” on page 8-30.

Comparing Modes

The following table compares the characteristics of Normal mode, Accelerator mode, and Rapid Accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Performance			
Run your model in a separate address space			✓

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Efficiently run batch and Monte Carlo simulations			✓
Model Adjustment			
Change model parameters such as solver, stop time without rebuilding	✓	✓	✓
Change block tunable parameters such as gain	✓	✓	✓
For more information on configuration set parameters which can be modified without requiring rebuild, see “Code Regeneration in Accelerated Models” on page 32-8			
Model Requirement			
Accelerate your model even if C code is not used for all blocks		✓	
Support Interpreted MATLAB Function blocks	✓	✓	
Support Non-Inlined MATLAB language or Fortran S-Functions	✓	✓	
Permit algebraic loops in your model	✓	✓	
Have your model work with the debugger or profiler	✓	✓	
Have your model include C++ code	✓	✓	
Data Display			
Use scopes and signal viewers	✓	✓	See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 32-19
Use scopes and signal viewers when running your model from the command line	✓	✓	

Note: Scopes and viewers do not update if you run your model from the command line in Rapid Accelerator mode.

Decision Tree

Use this decision tree to select between Normal, Accelerator, or Rapid Accelerator modes.

See “Comparing Performance” on page 32-34 to understand how effective the accelerator modes will be in improving the performance of your model.

Design Your Model for Effective Acceleration

In this section...

"Select Blocks for Accelerator Mode" on page 32-17
"Select Blocks for Rapid Accelerator Mode" on page 32-18
"Control S-Function Execution" on page 32-18
"Accelerator and Rapid Accelerator Mode Data Type Considerations" on page 32-19
"Behavior of Scopes and Viewers with Rapid Accelerator Mode" on page 32-19
"Factors Inhibiting Acceleration" on page 32-20

Select Blocks for Accelerator Mode

The Accelerator simulation mode runs the following blocks as if you were running Normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, the Accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- `Display`
- `From File`
- `From Workspace`
- `Inport` (root level only)
- `Interpreted MATLAB Function`
- `Outport` (root level only)
- `Scope`
- `To File`
- `To Workspace`
- `XY Graph`

Note: In some instances, Normal mode output might not precisely match the output from Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in Rapid Accelerator mode.

Additionally, Rapid Accelerator mode does not work if your model contains any of the following blocks:

- `Interpreted MATLAB Function`
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

Note: In some instances, Normal mode output might not precisely match the output from Rapid Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Control S-Function Execution

Inlining S-functions using the Target Language Compiler increases performance with the Accelerator mode by eliminating unnecessary calls to the Simulink application program interface (API). By default, however, the Accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The Rapid Accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the Simulink software runs on the host system rather than the target, it cannot access the targets I/O registers and so would fail when attempting to do so.

To direct the Accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid Accelerator mode does not support fixed-point signals or vectors greater than 32 bits.
- Rapid Accelerator mode supports fixed-point parameters up to 128 bits.
- Rapid Accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid Accelerator mode supports root inputs of Enumerated data type
- Rapid Accelerator mode does not support fixed-point data for the `From Workspace` block.
- Rapid Accelerator mode ignores the selection of the **Log fixed-point data as a fi object** (FixptAsFi) check box for the `To Workspace` block.
- Rapid Accelerator mode supports bus objects as parameters.
- The Accelerator mode and Rapid Accelerator mode store integers as compactly as possible.
- Fixed-Point Designer does not collect min, max, or overflow data in the Accelerator or Rapid Accelerator modes.
- Accelerator mode does not support runtime diagnostics

Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation from the command line or the menu determines the behavior of scopes and viewers in Rapid Accelerator mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Simulink Scope blocks	Same support as Normal mode	• Logging is supported • Scope window is not updated
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in External mode	Not supported
Signal logging	Supported, with limitations listed in Signal Logging in Rapid Accelerator Mode.	Supported, with limitations listed in Signal Logging in Rapid Accelerator Mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Multirate signal viewers	Not supported	Not supported
Stateflow Chart blocks	Same support for chart animation as Normal mode	Not supported

Rapid Accelerator mode does not support multirate signal viewers such as the DSP System Toolbox spectrum scope or the Communications System Toolbox™ scatterplot, signal trajectory, or eye diagram scopes.

Note: Although scopes and viewers do not update when you run Rapid Accelerator mode from the command line, they do update when you use the menu. "Run Acceleration Mode from the User Interface" on page 32-25 shows how to run Rapid Accelerator mode from the menu. "Interact with the Acceleration Modes Programmatically" on page 32-28 shows how to run the simulation from the command line.

Factors Inhibiting Acceleration

- You cannot use the Accelerator or Rapid Accelerator mode if your model:
  - Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
  - Uses Fcn blocks containing trigonometric functions having complex inputs.
- In some cases, changes associated with external or custom code do not cause Accelerator or Rapid Accelerator simulation results to change. These include:
  - TLC code
  - S-function source code, including rtwmakecfg.m files
  - Integrated custom code
  - S-Function Builder

  In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as slprj or the generated model code folder.

Rapid Accelerator Mode Limitations

- Rapid Accelerator mode does not support:
  - Algebraic loops.
  - Targets written in C++.
  - `Interpreted MATLAB Function` blocks.
  - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC). For more information, see "Write Fully Inlined S-Functions".
  - 3-D signals.
  - Debugger or Profiler.
  - Run time objects for `Simulink.RunTimeBlock` and `Simulink.BlockCompOutputPortData` blocks.
- Model parameters must be one of these data types:
  - `boolean`
  - `uint8` or `int8`
  - `uint16` or `int16`
  - `uint32` or `int32`
  - `single` or `double`
  - Fixed-point
  - Enumerated
- You cannot pause a simulation in Rapid Accelerator mode.
- For models that contain S-functions, ensure that the source files (.h, .c, and .cpp) for the S-function are in the same folder as the S-function MEX-file. See Implicit Build Support for more information. You can include additional files to an S-function or bypass the path limitation by using the rtwmakecfg.m file. For more information, see Use rtwmakecfg.m API to Customize Generated Makefiles.
- If a Rapid Accelerator build includes referenced models (by using `Model` blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the

number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See "Code Regeneration in Accelerated Models" on page 32-8 for more information.

- For root inports, Rapid Accelerator mode supports only base as the `Srcworkspace`.
- For root inports, when you specify the minimum and maximum values that the block should output, Rapid Accelerator mode does not recognize these limits during simulation.
- In Rapid Accelerator mode, `To File` or `To Workspace` blocks inside function-call subsystems do not generate any logging files if the function-call port is grounded or unconnected.

Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by Accelerator mode and Rapid Accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in "Construction of Generated Identifiers". Additional keywords that apply only to the Accelerator and Rapid accelerator modes are:

muDoubleScalarAbs	muDoubleScalarCos	muDoubleScalarMod
muDoubleScalarAcos	muDoubleScalarCosh	muDoubleScalarPower
muDoubleScalarAcosh	muDoubleScalarExp	muDoubleScalarRound
muDoubleScalarAsin	muDoubleScalarFloor	muDoubleScalarSign
muDoubleScalarAsinh	muDoubleScalarHypot	muDoubleScalarSin
muDoubleScalarAtan,	muDoubleScalarLog	muDoubleScalarSinh
muDoubleScalarAtan2	muDoubleScalarLog10	muDoubleScalarSqrt
muDoubleScalarAtanh	muDoubleScalarMax	muDoubleScalarTan
muDoubleScalarCeil	muDoubleScalarMin	muDoubleScalarTanh

Perform Acceleration

In this section...
"Customize the Build Process" on page 32-24
"Run Acceleration Mode from the User Interface" on page 32-25
"Making Run-Time Changes" on page 32-26

Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

1. From the **Simulation** menu, select **Model Configuration Parameters**.
2. In the Configuration Parameters dialog box, select the **All Parameters** tab, and then from the **Compiler optimization level** drop-down list, select `Optimizations on (faster runs)`.

   Code generation takes longer with this option, but the model simulation runs faster.
3. Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

Changing the Location of Generated Code

By default, the Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/`*modelname* (for example, `slprj/accel/f14`), and places a compiled MEX-file in the current working folder. To change the name of the folder into which the Accelerator Mode writes generated code:

1. In the Simulink editor window, select **File > Simulink Preferences**.

   The Simulink Preferences window appears.
2. In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
3. Enter the absolute or relative path to your subfolder and click **Apply**.

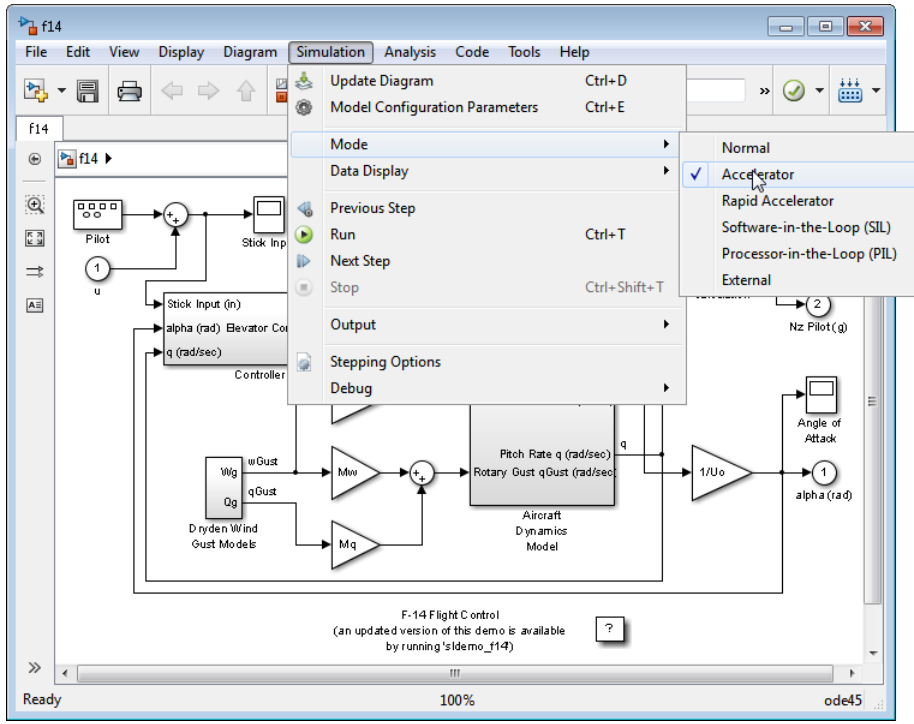
Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then from the **Simulation** > **Mode** menu, select either **Accelerator** or **Rapid Accelerator**. Then start the simulation.

The following example shows how to accelerate the already opened `f14` model using the Accelerator mode:

1 From the **Simulation** > **Mode** menu, select **Accelerator**.

Alternatively, you can select `Accelerator` from the Simulink Editor toolbar.



2 From the **Simulation** menu, select **Run**.

The Accelerator and Rapid Accelerator modes first check to see if code was previously compiled for your model. If code was created previously, the Accelerator or Rapid Accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see "Code Regeneration in Accelerated Models" on page 32-8.

The Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/`*modelname* (for example, `slprj/accel/f14`), and places a compiled MEX-file in the current working folder. If you want to change this path, see "Changing the Location of Generated Code" on page 32-24.

The Rapid Accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/`*modelname* (for example, `slprj/raccel/f14`).

Note: The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in Accelerator or Rapid Accelerator mode.

Making Run-Time Changes

A feature of the Accelerator and Rapid Accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in Rapid Accelerator mode than when in Accelerator mode. For instance, changing the stop time in Rapid Accelerator mode causes code to regenerate, but does not cause Accelerator mode to regenerate code.

Interact with the Acceleration Modes Programmatically

In this section...
"Why Interact Programmatically?" on page 32-28
"Build Accelerator Mode MEX-files" on page 32-28
"Control Simulation" on page 32-28
"Simulate Your Model" on page 32-29
"Customize the Acceleration Build Process" on page 32-30

Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation from the command prompt or from MATLAB script. With this flexibility, you can create Accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use the Accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

Build Accelerator Mode MEX-files

With the `accelbuild` command, you can build the Accelerator mode MEX-file without actually simulating the model. For example, to build an Accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

Control Simulation

You can control the simulation mode from the command line prompt by using the `set_param` command:

```
set_param('modelname','SimulationMode','mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model with the Accelerator mode, you would use:

```
set_param('myModel','SimulationMode','accelerator')
```

However, a preferable method is to specify the simulation mode within the `sim` command:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than *`modelname`* if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system in the Rapid Accelerator mode, you would use:

```
simOut = sim(bdroot,'SimulationMode','rapid');
```

Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelname', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for *`modelname`* if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` command first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see "Code Regeneration in Accelerated Models" on page 32-8 for a description), the `sim` command executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

Simulation Example

The following sequence shows how to programmatically simulate `myModel` in Rapid Accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid'...
```

```
'StopTime', '10000');
```

Use the `sim` command again to resimulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

Customize the Acceleration Build Process

You can programmatically control the Accelerator mode and Rapid Accelerator mode build process and the amount of information displayed during the build process. See "Customize the Build Process" on page 32-24 for details on why doing so might be advantageous.

Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

Run Accelerator Mode with the Simulink Debugger

In this section...
"Advantages of Using Accelerator Mode with the Debugger" on page 32-32
"How to Run the Debugger" on page 32-32
"When to Switch Back to Normal Mode" on page 32-32

Advantages of Using Accelerator Mode with the Debugger

The Accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use the Accelerator mode to simulate a large model and quickly reach a distant break point.

For more information, see "Accelerator Mode" on page 32-5.

Note: You cannot use the Rapid Accelerator mode with the debugger.

How to Run the Debugger

To run your model in the Accelerator mode with the debugger:

1. From the **Simulation** > **Mode** menu, select **Accelerator**.
2. At the command prompt, enter:

   ```
   sldebug modelname
   ```

3. At the debugger prompt, set a time break:

   ```
   tbreak 10000
   continue
   ```

4. Once you reach the breakpoint, use the debugger command `emode` (execution mode) to toggle between Accelerator and Normal mode.

When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- `trace`
- `break`
- `zcbreak`
- `nanbreak`

Comparing Performance

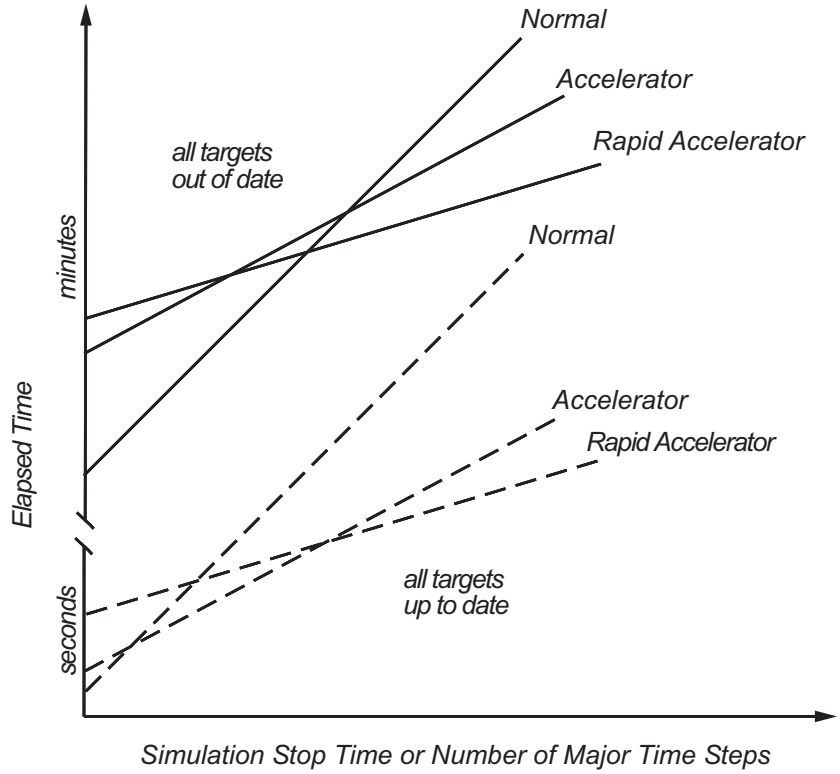
In this section...
“Performance of the Simulation Modes” on page 32-34
“Measure Performance” on page 32-36

Performance of the Simulation Modes

The Accelerator and Rapid Accelerator modes give the best speed improvement compared to Normal mode when simulation execution time exceeds the time required for code generation. For this reason, the Accelerator and Rapid Accelerator modes generally perform better than Normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over Normal mode because in Normal mode these blocks also simulate through code generation.

Including tunable parameters in your model can also increase the simulation time.

The figure shows in general terms the performance of a hypothetical model simulated in Normal, Accelerator, and Rapid Accelerator modes.



Performance When the Target Must Be Rebuilt

The solid lines in the figure show performance when the target code must be rebuilt ("all targets out of date"). For this hypothetical model, the time scale is on the order of minutes, but it could be longer for more complex models.

As generalized in the figure, the time required to compile the model in Normal mode is less than the time required to build either the Accelerator target or Rapid Accelerator executable. It is evident from the figure that for small simulation stop times Normal mode results in quicker overall simulation times than either Accelerator mode or Rapid Accelerator mode.

The crossover point where Accelerator mode or Rapid Accelerator mode result in faster execution times depends on the complexity and content of your model. For instance, those models running in Accelerator mode containing large numbers of blocks using

interpreted code (see "Select Blocks for Accelerator Mode" on page 32-17) might not run much faster than they would in Normal mode unless the simulation stop time is very large. Similarly, models with a large number of Stateflow Chart blocks or MATLAB Function blocks might not show much speed improvement over Normal mode unless the simulation stop times are long.

For illustration purposes, the graphic represents a model with a large number of Stateflow Chart blocks or MATLAB Function blocks. The curve labeled "Normal" would have much smaller initial elapsed time than shown if the model did not contain these blocks.

Performance When the Targets Are Up to Date

As shown by the broken lines in the figure ("all targets up to date") the time for the Simulink software to determine if the Accelerator target or the Rapid Accelerator executable are up to date is significantly less than the time required to generate code ("all targets out of date"). You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the Accelerator mode target code once and use it to simulate your model with a series of gain settings. This is an especially efficient way to use the Accelerator or Rapid Accelerator modes because this type of change does not result in the target code being regenerated. This means the target code is generated the first time the model runs, but on subsequent runs the Simulink code spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. This means subsequent runs of your model might simulate faster in Accelerator or Rapid Accelerator mode when compared to Normal mode, even for short stop times.

Measure Performance

You can use the `tic`, `toc`, and `sim` commands to compare Accelerator mode or Rapid Accelerator mode execution times to Normal mode.

1. Open your model.
2. From the **Simulation** > **Mode** menu, select **Normal**.
3. Use the `tic`, `toc`, and `sim` commands at the command line prompt to measure how long the model takes to simulate in Normal mode:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

`tic` and `toc` work together to record and return the elapsed time and display a message such as the following:

```
Elapsed time is 17.789364 seconds.
```

4. Select either **Accelerator** or **Rapid Accelerator** from the **Simulation** > **Mode** menu, and build an executable for the model by clicking the **Run** button. The acceleration modes use this executable in subsequent simulations as long as the model remains structurally unchanged. "Code Regeneration in Accelerated Models" on page 32-8 discusses the things that cause your model to rebuild.
5. Rerun the compiled model at the command prompt:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

6. The elapsed time displayed shows the run time for the accelerated model. For example:

```
Elapsed time is 12.419914 seconds.
```

The difference in elapsed times (5.369450 seconds in this example) shows the improvement obtained by accelerating your model.

How to Improve Performance in Acceleration Modes

In this section...
“Techniques” on page 32-38 “C Compilers” on page 32-38

Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

On this pane...	Set...	To...
All Parameters tab	**Solver data inconsistency**	none
All Parameters tab	**Array bounds exceeded**	none
All Parameters tab	**Signal storage reuse**	selected

- Disable Stateflow debugging and animation.
- Inline user-written S-functions (these are TLC files that direct the Simulink Coder software to create C code for the S-function). See “Control S-Function Execution” on page 32-18 for a discussion on how the Accelerator mode and Rapid Accelerator mode work with inlined S-functions.

  For information on how to inline S-functions, consult “S-Functions and Code Generation”.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 32-24.

C Compilers

On computers running the Microsoft Windows operating system, the Accelerator and Rapid Accelerator modes use the default 64-bit C compiler supplied by MathWorks to

compile your model. If you have a C compiler installed on your PC, you can configure the `mex` command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

Note: For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

`http://www.mathworks.com/support/compilers/current_release/`

Nonvirtual and Virtual Blocks

When creating models, you need to be aware that Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks. Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model's behavior. Virtual blocks, by contrast, play no active role in the simulation; they help organize a model graphically. Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks. The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
`Bus Assignment`	Virtual if input bus is virtual.
`Bus Creator`	Virtual if output bus is virtual.
`Bus Selector`	Virtual if input bus is virtual.
`Demux`	Always virtual.
`Enable`	Virtual unless connected directly to an `Outport` block.
`From`	Always virtual.
`Goto`	Always virtual.
`Goto Tag Visibility`	Always virtual.
`Ground`	Always virtual.
`Inport`	Virtual *unless* the block resides in a conditionally executed or atomic subsystem *and* has a direct connection to an `Outport` block.
`Mux`	Always virtual.
`Outport`	Virtual when the block resides within any subsystem block (conditional or not), and does *not* reside in the root (top-level) Simulink window.
`Selector`	Virtual only when **Number of input dimensions** specifies `1` and **Index Option** specifies `Select all`, `Index vector (dialog)`, or `Starting index (dialog)`.
`Signal Specification`	Always virtual.
`Subsystem`	Virtual unless the block is conditionally executed or the **Treat as atomic unit** check box is selected.

Block Name	Condition Under Which Block Is Virtual
	You can check if a block is virtual with the `IsSubsystemVirtual` block property. See "Block-Specific Parameters".
`Terminator`	Always virtual.
`Trigger`	Virtual when the output port is *not* present.

- "Block Libraries"

Set Block Properties

For each block in a model, you can set general block properties, such as:

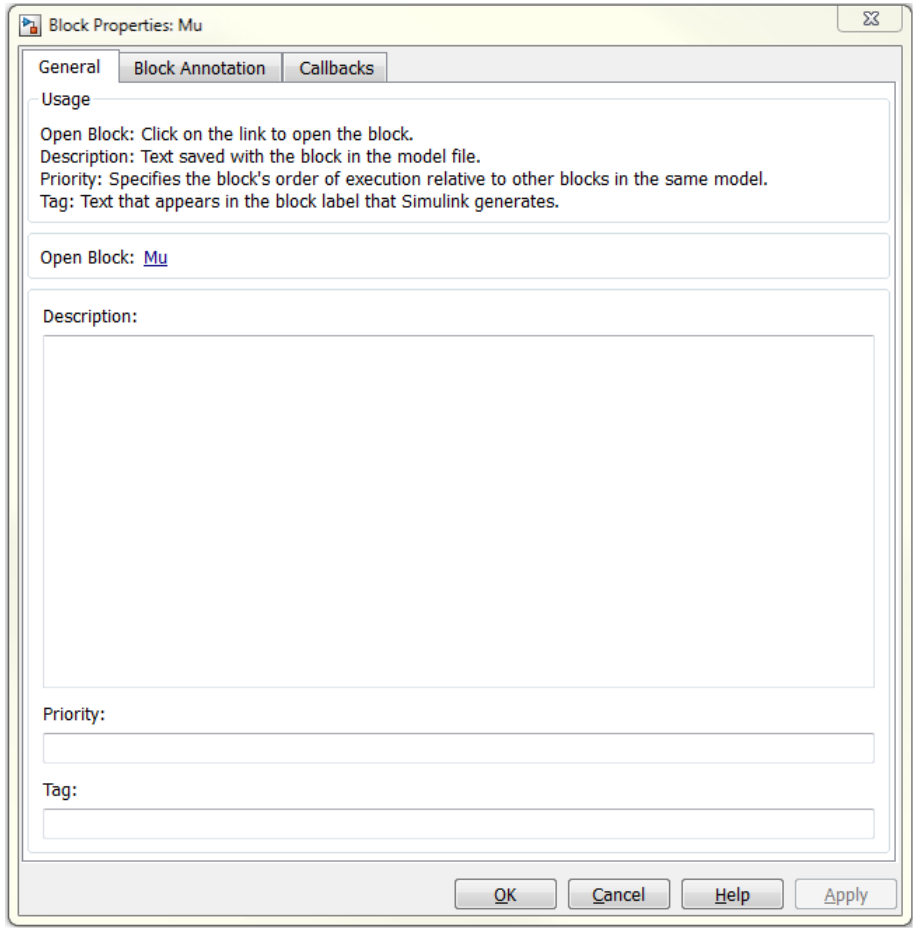
- A description of the block
- The block's order of execution
- A block annotation
- Block callback functions

Block Properties Dialog Box

To set these block properties, open the Block Properties dialog box.

1. In the Simulink Editor, select the block.
2. Select **Diagram** > **Properties**. Alternatively, right-click the block and select **Block Properties**.

The Block Properties dialog box opens, with the **General** tab open. For example:



To open the Block Parameters dialog box for the block, in the General tab of the Block Properties dialog box, click the **Open Block** link. Use the Block Parameters dialog box to specify values for attributes that are specific each block.

Note Some blocks, such as Scope blocks, do not have a Block Parameters dialog box.

Using the Block Properties dialog box **Open Block** link to open the Block Parameters dialog box works for all blocks that have parameter dialog boxes, except for `Subsystem`

and `Model` blocks. Use the Simulink Editor **Diagram** menu or the block context menu to open the Block Parameters dialog box for Subsystem and Model blocks.

General Block Properties

Description

Enter a brief description of the purpose of the block or any other descriptive information.

Priority

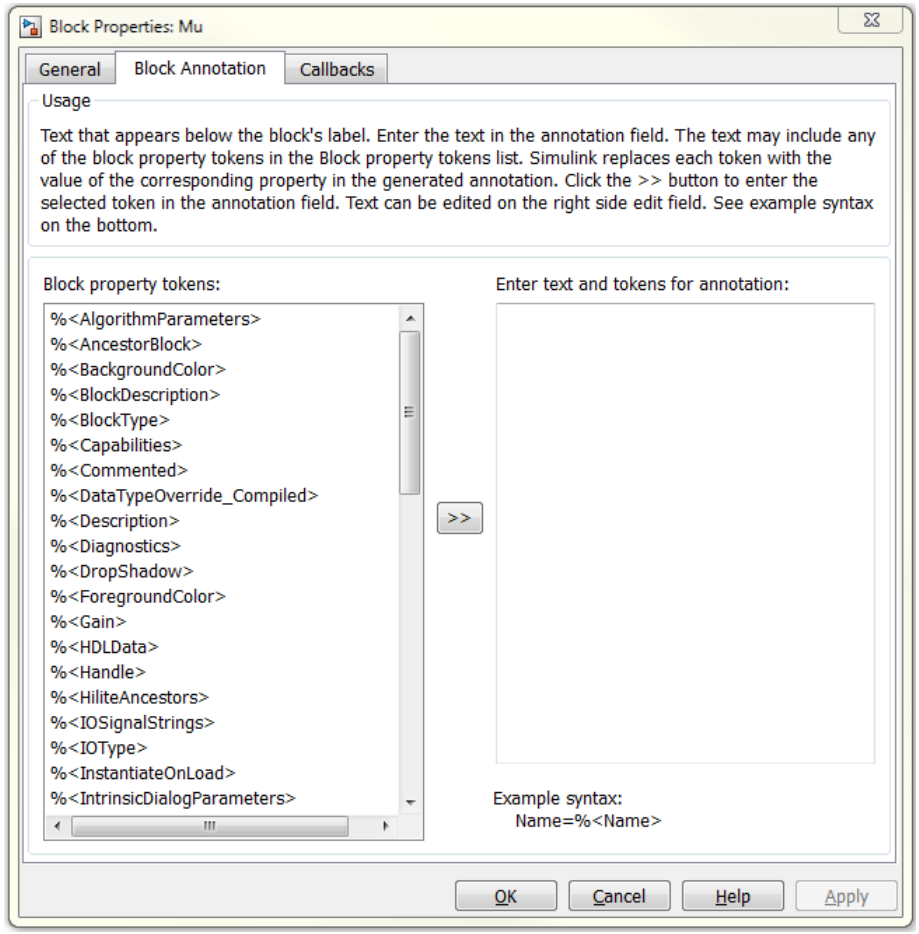
Specify the execution priority of this block relative to other blocks in the model. For more information, see “Assign Block Priorities” on page 33-43.

Tag

You can use a tag to create your own block-specific label for a block. Specify text that Simulink assigns to the block's Tag parameter and saves with the block in the model.

Block Annotation Properties

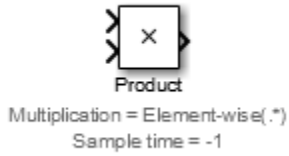
Use the **Block Annotation** tab to display the values of selected block parameters in an annotation that appears beneath the block's icon.



Enter the text of the annotation in the text field that appears on the right side of the pane. The text can include any of the block property tokens that appear in the list on the left side of the pane. A block property token is simply the name of a block parameter preceded by `%<` and followed by `>`. When displaying the annotation, Simulink replaces the tokens with the values of the corresponding block parameters. For example, suppose that you enter the following text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor model window, the annotation appears as follows:

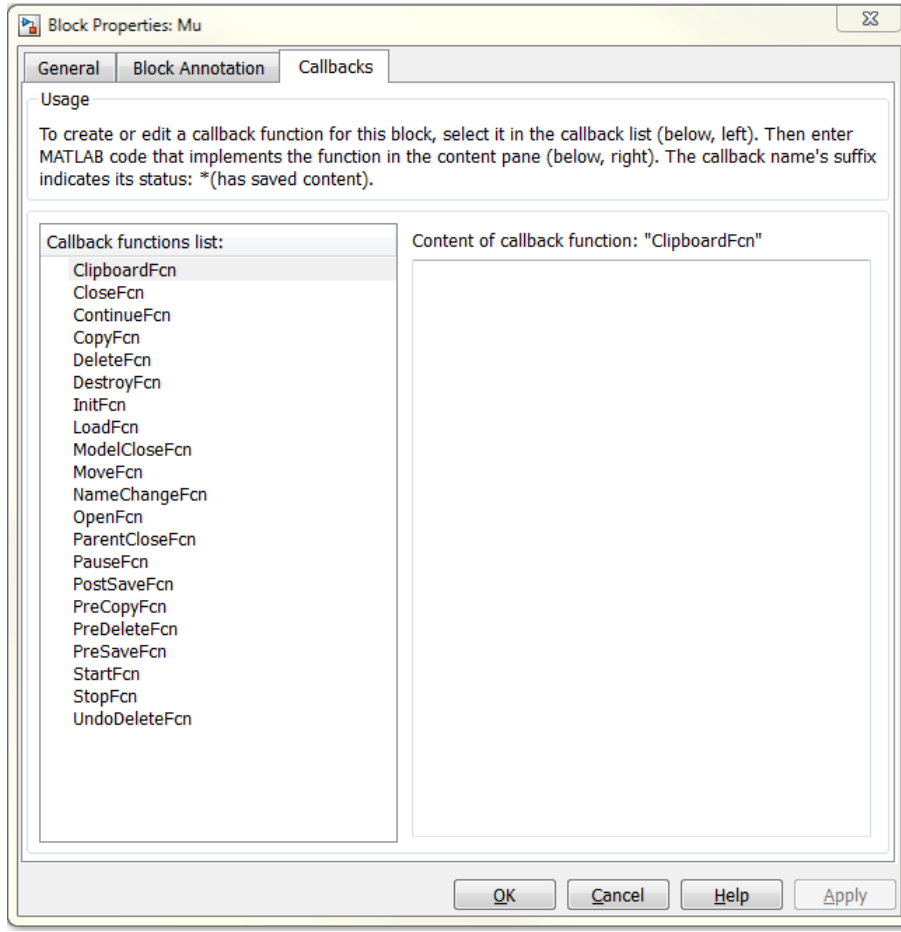


The block property token list on the left side of the pane lists all the parameters that are valid for the currently selected block (see “Common Block Properties” and “Block-Specific Parameters”). To add one of the listed tokens to the text field on the right side of the pane, select the token and then click the button between the list and the text field.

You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 33-10.

Block Callbacks

Use the **Callbacks** tab to specify implementations for a block's callbacks (see “Callbacks for Customized Model Behavior” on page 4-70).



To specify an implementation for a callback, select the callback in the callback list on the left side of the pane. Then enter MATLAB commands that implement the callback in the right-hand field. Click **OK** or **Apply** to save the change. Simulink appends an asterisk to the name of the saved callback to indicate that it has been implemented.

Modify Behavior for Opening a Block

You can use the `OpenFcn` callback to automatically execute MATLAB scripts when the you double-click a block. MATLAB scripts can perform many different tasks, such

as defining variables for a block, making a call to MATLAB that brings up a plot of simulated data, or generating a GUI.

The `OpenFcn` overrides the normal behavior which occurs when opening a block (its parameter dialog box is displayed or a subsystem is opened).

To create block callbacks interactively, open the block's Block Properties dialog box and use the **Callbacks** tab to edit callbacks (see "Callbacks for Customized Model Behavior" on page 4-70).

To create the `OpenFcn` callback programmatically, click the block to which you want to add this property, then enter the following at the MATLAB command prompt:

```
set_param(gcb,'OpenFcn','expression')
```

where `expression` is a valid MATLAB command or a MATLAB script that exists in your MATLAB search path.

The following example shows how to set up the callback to execute a MATLAB script called `myfunction.m` when double clicking a subsystem called `mysubsystem`.

```
set_param('mymodelname/mysubsystem','OpenFcn','myfunction')
```

Create Block Annotations Programmatically

You can use a block's `AttributesFormatString` parameter to display selected block parameters beneath the block as an "attributes format string," which is a string that specifies values of the block's attributes (parameters). "Common Block Properties" and "Block-Specific Parameters" describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the desired attributes format string.

The attributes format string can be any text string that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format string beneath the block's icon, replacing each parameter name with the corresponding parameter value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, enter the following at the MATLAB command prompt:

```
set_param(gcb, 'AttributesFormatString','pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays the following block annotation:

If a parameter's value is not a string or an integer, Simulink displays `N/S` (not supported) for the parameter's value. If the parameter name is invalid, Simulink displays `???` as the parameter value.

Change the Appearance of a Block

In this section...
“Change a Block Orientation” on page 33-12
“Resize a Block” on page 33-14
“Displaying Parameters Beneath a Block” on page 33-15
“Drop Shadows” on page 33-15
“Manipulate Block Names” on page 33-15
“Specify Block Color” on page 33-17

Change a Block Orientation

By default, a block is oriented so that its input ports are on the left, and its output ports are on the right. You can change the orientation of a block by rotating it 90 degrees around its center or by flipping it 180 degrees around its horizontal or vertical axis.

- “How to Rotate a Block” on page 33-12
- “How to Flip a Block” on page 33-13

How to Rotate a Block

You can rotate a block 90 degrees by selecting one of these commands from the **Diagram** menu:

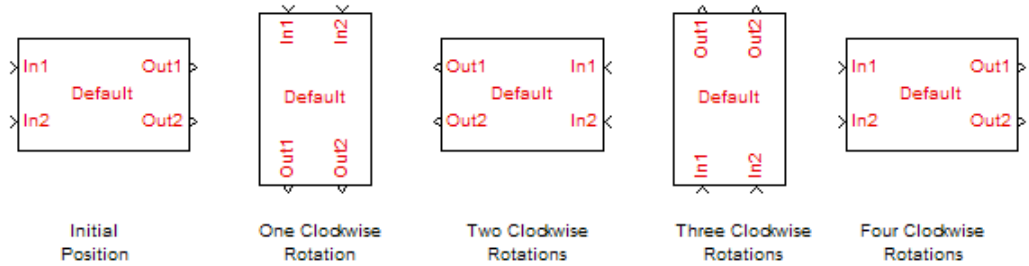
- **Rotate & Flip > Clockwise** (or **Ctrl+R**)
- **Rotate & Flip > Counterclockwise**

A rotation command effectively moves a block's ports from its sides to its top and bottom or from its top and bottom to its size, depending on the initial orientation of the block. The final positions of the block ports depend on the block's *port rotation type*.

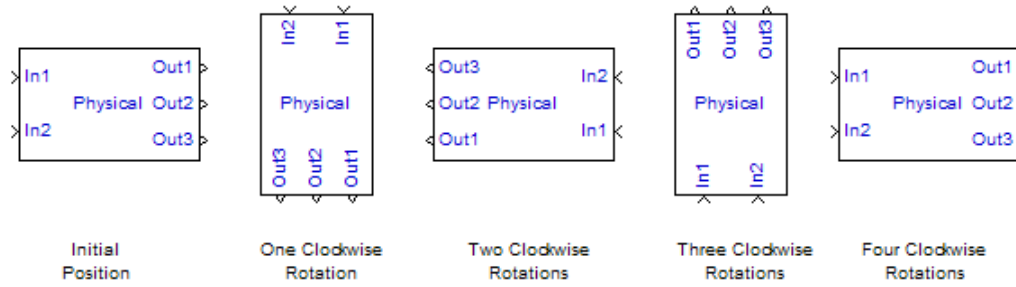
Port Rotation Type

After rotating a block clockwise, Simulink may, depending on the block, reposition the block's ports to maintain a left-to-right port numbering order for ports along the top and bottom of the block and a top-to-bottom port numbering order for ports along the

left and right sides of the block. A block whose ports are reordered after a clockwise rotation is said to have a *default port rotation* type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. All nonmasked blocks and all masked blocks by default have the default rotation policy. The following figure shows the effect of using the **Rotate & Flip > Clockwise** command on a block with the default rotation policy.



A masked block can optionally specify that its ports not be reordered after a clockwise rotation (see “Port rotation”). Such a block is said to have a *physical port rotation* type. This policy facilitates layout of diagrams in mechanical and hydraulic systems modeling and other applications where diagrams do not have a preferred orientation. The following figure shows the effect of clockwise rotation on a block with a physical port rotation type

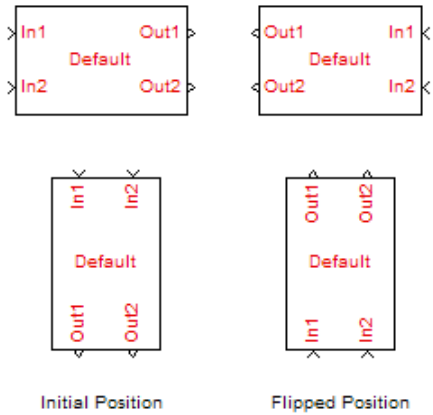


How to Flip a Block

Simulink provides a set of commands that allow you to flip a block 180 degrees about its horizontal or vertical axis. The commands effectively move a block's input and output

ports to opposite sides of the block or reverse the ordering of the ports, depending on the block's port rotation type.

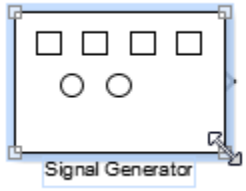
A block with the default rotation type has one flip command: **Diagram > Rotate & Flip > Flip Block** (**Ctr+I**). This command effectively moves the block's input and output ports to the side of the block opposite to the side on which they are initially located, i.e., from the left to the right side or from the top to the bottom side.



Resize a Block

To change the size of a block, select it, then drag any of its selection handles. While you hold down the mouse button, a dotted rectangle shows the new block size. When you release the mouse button, the block is resized.

For example, the following figure below shows a Signal Generator block being resized. The lower-right handle was selected and dragged to the cursor position. When the mouse button is released, the block takes its new size.



Tip Use the model editor's resize blocks commands to make one block the same size as another (see "Align, Distribute, and Resize Groups of Blocks" on page 4-18).

Displaying Parameters Beneath a Block

You can cause Simulink to display one or more of a block's parameters beneath the block. Specify the parameters to be displayed by using one of the following approaches:

- Enter an attributes format string in the **Attributes format string** field of the block's **Properties** dialog box (see "Set Block Properties" on page 33-4)
- Set the value of the block's `AttributesFormatString` property to the format string, using `set_param`

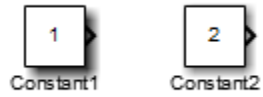
Drop Shadows

By default, blocks appear with a drop shadow.

To increase the depth of a block drop shadow:

1. Select the block.
2. Select **Diagram** > **Format** > **Block Shadow**.

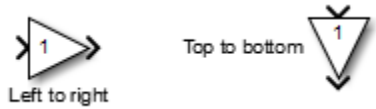
For example, in this model, the `Constant1` block has the **Block Shadow** option enabled, and the `Constant2` block uses the default drop shadow.



To remove the default drop shadows for all blocks, select **File** > **Simulink Preferences** > **Editor Defaults** > **Use classic diagram theme**.

Manipulate Block Names

All block names in a model must be unique and must contain at least one character. By default, block names appear below blocks whose ports are on the sides, and to the left of blocks whose ports are on the top and bottom, as the following figure shows:



Note Simulink commands interprets a forward slash (/) as a block path delimiter. For example, the path `vdp/Mu` designates a block named `Mu` in the model named `vdp`. Therefore, avoid using forward slashes (/) in block names to avoid causing Simulink to interpret the names as paths.

Change Block Names

You can edit a block name in one of these ways:

- To replace the block name, click the block name, select the entire name, and then enter the new name.
- To insert characters, click between two characters to position the insertion point, then insert text.
- To replace characters, drag the mouse to select a range of text to replace, then enter the new text.

To apply the block name edit, click the cursor anywhere else in the model, take any other action, or press **Esc**. If you try to change the name of a block to a name that already exists, Simulink displays an error message.

Note If you change the name of a library block, all links to that block become unresolved.

Change Font of Block Name

To modify the font used in a block name by selecting the block, then choosing the **Font Style** menu item from the **Diagram > Format** menu.

1. Select the block name.
2. Select **Diagram > Format > Font Style**.

   The Select Font dialog box opens.
3. Select a font and specify other font characteristics, such as the font size.

Note: Changing the block name font also changes the font of any text that appears inside the block.

This procedure also changes the font of any text that appears inside the block.

Change the Location of a Block Name

To change the location of the name of a selected block, use one of these approaches:

- Drag the block name to the opposite side of the block.
- Choose **Diagram > Rotate & Flip > Flip Block Name**. This command changes the location of the block name to the opposite side of the block.

For more information about block orientation, see "How to Rotate a Block" on page 33-12.

Hide a Block Name

By default the Simulink Editor displays the names of blocks (except for a few blocks, such as the Bus Creator block). To hide the name of a selected block, clear the **Diagram > Format > Show Block Name** menu option.

Specify Block Color

See "Specify Block Diagram Colors" on page 4-4 for information on how to set the color of a block.

More About

- "Nonvirtual and Virtual Blocks" on page 33-2

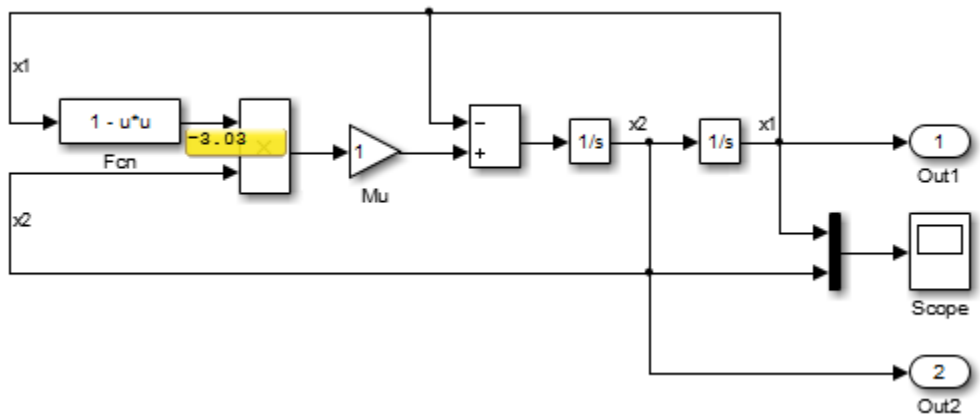
Display Port Values for Debugging

In this section...
"Display Port Values for Easy Debugging" on page 33-18
"Display Value for a Specific Port" on page 33-22
"Display Port Values for a Model" on page 33-25
"Port Value Display Limitations" on page 33-26

Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the port on the `Fcn` block, an output value of `–3.03`.

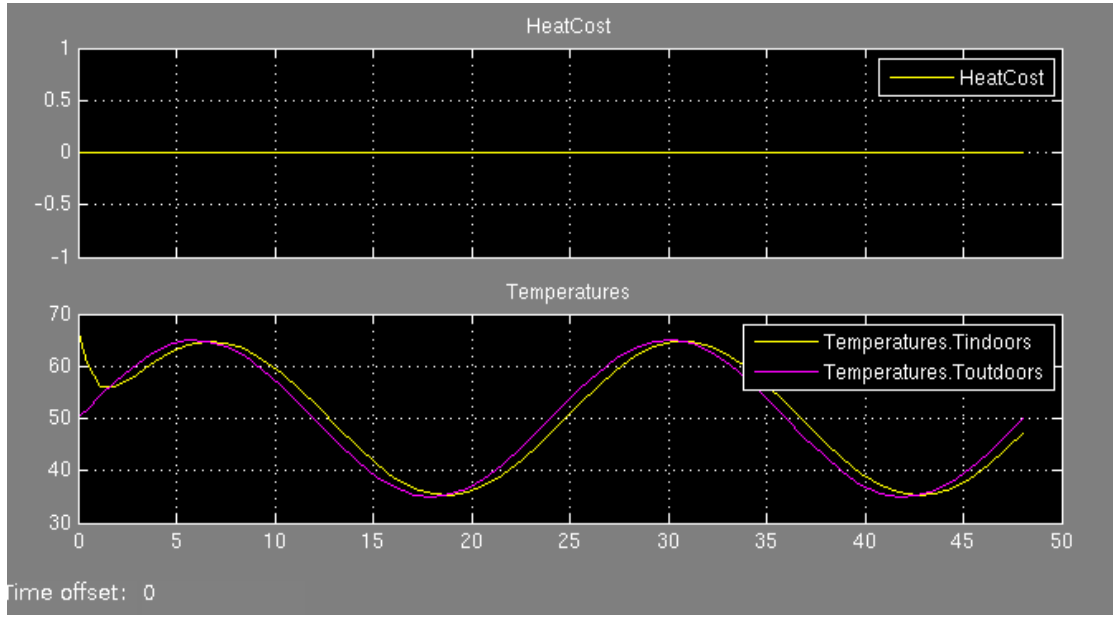


If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the string `optimized`.

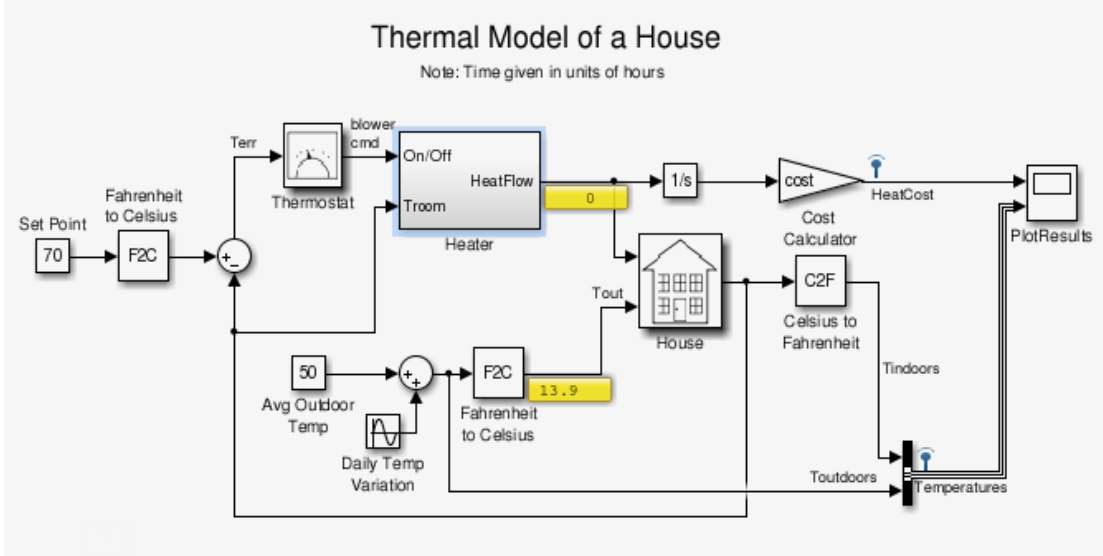
Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.



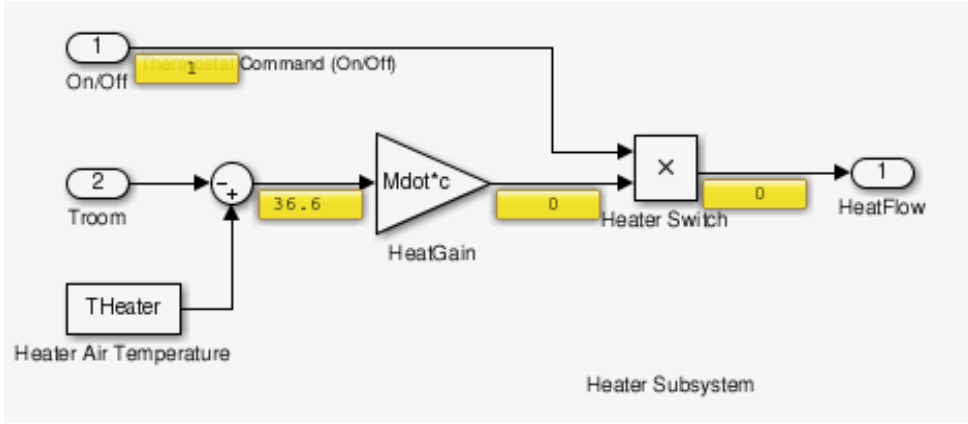
These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.



To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.



This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you monitor a signal value during simulation. However, these labels are not saved with a model.

For non-numeric data display, Simulink uses these strings:

Message	Explanation
`action`	The signal executes action subsystems.
`fcn-call`	The signal is a function-call signal, e.g., Function Call Generator output.
`ground`	The signal is coming from a Ground block.
`not a data signal`	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these strings:

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 33-25.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
`click to add signals`	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
`inaccessible`	Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 33-26.
`[m*n]`	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.
`no data yet`	This message appears when:

Message	Explanation
	• The simulation data is not available. Start the simulation to see values. • If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.
`not used`	Simulink cannot obtain the signal value due to optimization.
`removed`	Simulink cannot obtain the signal value due to block reduction.
`optimized`	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with **Conditional input branch execution** enabled. For more information, see "Conditional Execution Behavior" on page 10-54.
`unavailable`	The simulation data available is insufficient. For example, see "Simulation Stepper" on page 33-27.

Note: You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

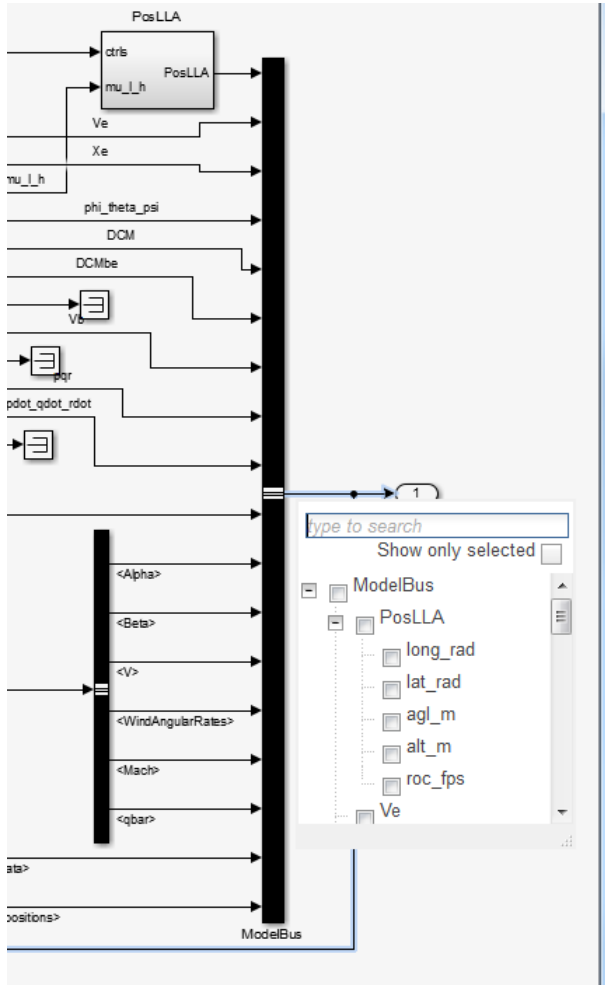
Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click on it during simulation. You can control this behavior in **Display > Data Display in Simulation > Options > Display values > Enable by default during simulation**.

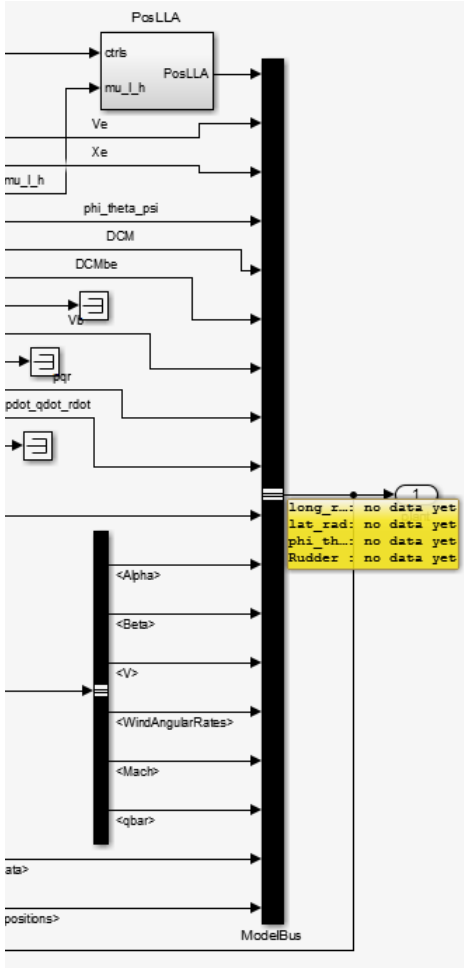
Note: To remove all data tips, select **Display > Data Display in Simulation > Remove All Value Labels**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

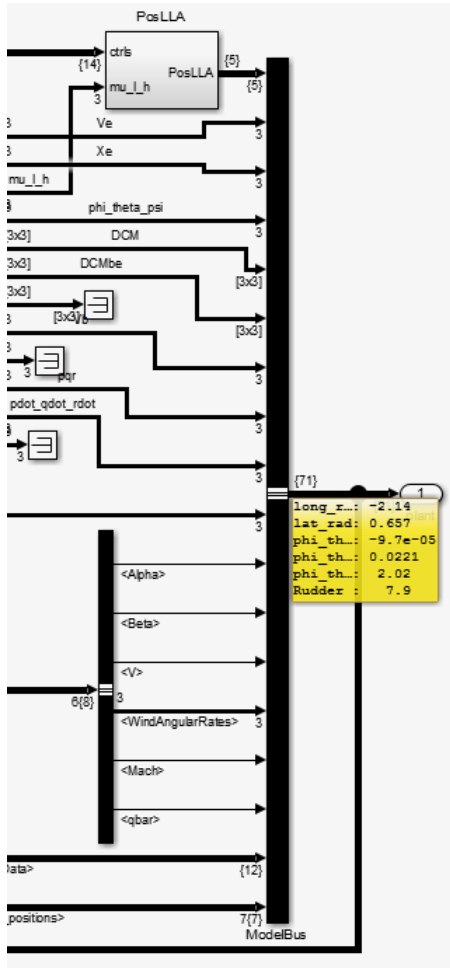


You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.



When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.



Note: Simulink does not save the values of a signal when you remove the port value label.

Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

1. In the model whose port values you want to display, select **Display > Data Display in Simulation > Options**.
2. In the Value Label Display Options dialog box, specify your preferences for:
   - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
   - The display mode
   - Floating-point or fixed-point format

Port Value Display Limitations

Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	• Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as `optimized`. For more information, see "Display Port Values for Easy Debugging" on page 33-18. • Model reference blocks simulated in Accelerator mode do not get their port value displays updated.
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see "Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim Target".

Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as `inaccessible`. You can disable signal

storage reuse using the **Configuration Parameters > All Parameters > Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Outport block displays the value of the Outport block, depending on the **Output when disabled** setting.
- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

Command-Line Simulations

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

Merge Block

Simulink does not display the output value of a merge block. To see this value, refer to the source block.

Command Line Interface

You cannot specify port value displays through the command line interface.

Non-Simulink signals

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

"Block Priority Violations" on page 33-47

What Is Sorted Order?

During the updating phase of simulation, Simulink determines the order in which to invoke the block methods during simulation. This block invocation ordering is the *sorted order*.

You cannot set this order, but you can assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks. Simulink tries to honor block priority settings, unless there is a conflict with data dependencies. To confirm the results of priorities that you have set, or to debug your model, display and review the sorted order of your nonvirtual blocks and subsystems.

Note: For more information about block methods and execution, see:

- "Block Methods" on page 3-15
- "Conditional Execution Behavior" on page 10-54

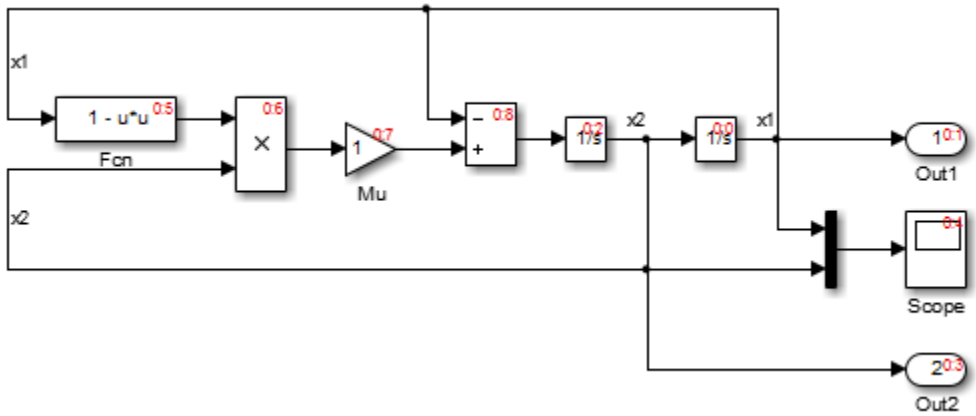
Display the Sorted Order

To display the sorted order of the `vdp` model:

1. Open the van der Pol equation model:

   ```
   vdp
   ```

2. In the model window, select **Display** > **Blocks** > **Sorted Execution Order**.



Simulink displays a notation in the top-right corner of each nonvirtual block and each nonvirtual subsystem. These numbers indicate the order in which the blocks execute. The first block to execute has a sorted order of `0`.

For example, in the van der Pol equation model, the Integrator block with the sorted order `0:0` executes first. The Out1 block, with the sorted order `0:1`, executes second. Similarly, the remaining blocks execute in numeric order from `0:2` to `0:8`.

You can save the sorted order setting with your model. To display the sorted order when you reopen the model, select **Simulation > Update diagram**.

Sorted Order Notation

The sorted order notation varies depending on the type of block. The following table summarizes the different formats of sorted order notation. Each format is described in detail in the sections that follows the table.

Block Type	Sorted Order Notation	Description
"Nonvirtual Blocks" on page 33-33	*s*`:`*b* *s*`:`*b* {*x*, *y*}	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always `0`. • *b* specifies the block position within the sorted order for the designated execution context.

Block Type	Sorted Order Notation	Description
		• *x*,*y* are the system indices of the subsystems whose execution is controlled by this block.
"Nonvirtual Subsystems" on page 33-34 (not including function-call and action subsystems)	*s*:*b*	• *s* is the system index of the model or subsystem. • *b* specifies the block position within the sorted order for the designated execution context.
"Virtual Blocks and Subsystems" on page 33-36	Not applicable	Virtual blocks do not execute.
Action Subsystems	*s*:*b*'	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • *b*' is the block index of the action block (but not of the action subsystem).
"Function-Call Subsystems" on page 33-37 and Function-Call models	One non-grounded initiator: *s*:b^{i}	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^{i} is the block index of the root initiator in the subsystem's hierarchy.
	Two or more initiators: • *s*:b^{i1}, *s*:b^{i2}, ..., *s*:b^{in} where n is the number of non-grounded initiators.	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^{i_n} is the block index of the n-th root initiator in the subsystem's hierarchy.
	Initiators are either Ground blocks or are unconnected: • *s*:G	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • *G* indicates that all function-call initiators are grounded.

Block Type	Sorted Order Notation	Description
"Branched Function-Call Signals" on page 33-39	$s:b^i[B_k]$	• s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. • b^i is the block index of the root initiator in the subsystem's hierarchy. • B_k indicates that it is a branched function-call subsystem with branch index k.
Function-Call Feedback Latch Blocks	$s:b^i[B_m]$	• s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. • b^i is the block index of the root initiator in the subsystem's hierarchy. • B_m indicates that it is a branched subsystem with branch index m.
Blocks in a model with asynchronous function-call inputs	Function-call root-level Inport and Outport blocks: F_i	• F indicates that it is executed in a function-call context. • i is the function-call index.
	Root-level data Inport blocks: If they drive a function-call subsystem, it is the function-call index of the subsystem. If they are part of the model that is not driven by asynchronous function-call inputs, then no function-call index is displayed.	
	Root-level function-call blocks: F_i Root-level branched function-call blocks: $F_i[B_k]$	• F indicates that it is executed in a function-call context. • i is the function-call index.

Block Type	Sorted Order Notation	Description
Blocks inside Export Function Models (See "Execution Order for Function-Call Root-level Inport Blocks" on page 10-8)	Function-call root-level Inport and Outport blocks: F_i	• F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport or Outport block in normal simulation mode.
	Root-level function-call subsystems: F_i Root-level branched function-call subsystems: $F_i[B_k]$	• F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport block in normal simulation mode. • B_k indicates a branched function-call subsystem with index k.
	Merge and Data Store Memory blocks: $F_i, F_j, \ldots$	• F indicates that it is a function-call block. • i is the block execution index.
	Root-level data Inport and Outport blocks: Same execution order as the function-call subsystems they are connected to.	
"Bus-Capable Blocks" on page 33-40	`s:B`	• `s` is the system index of the model or subsystem the block resides in. For root-level models, `s` is always `0`. • `B` indicates a bus-capable block.

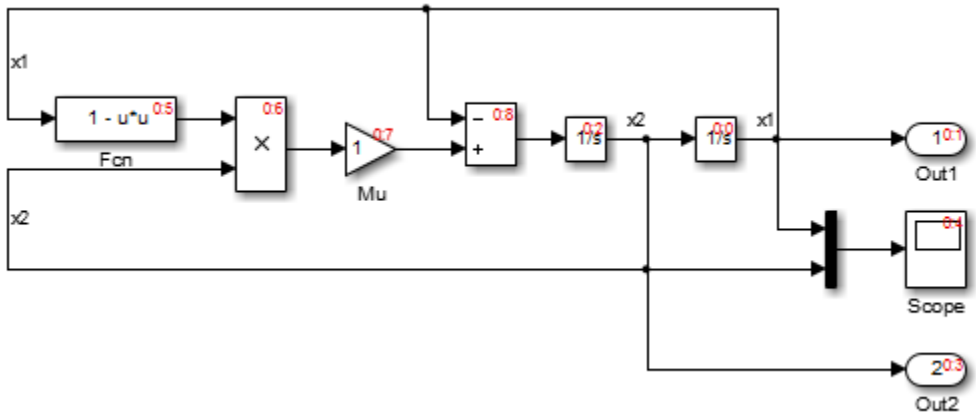
Nonvirtual Blocks

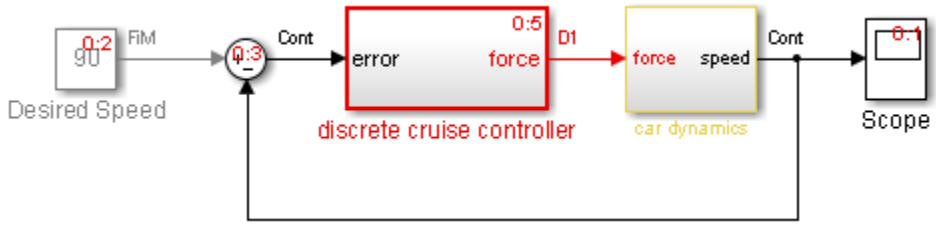
In the van der Pol equation model, all the nonvirtual blocks in the model have a sorted order. The system index for the top-level model is `0`, and the block execution order ranges from `0` to `8`.



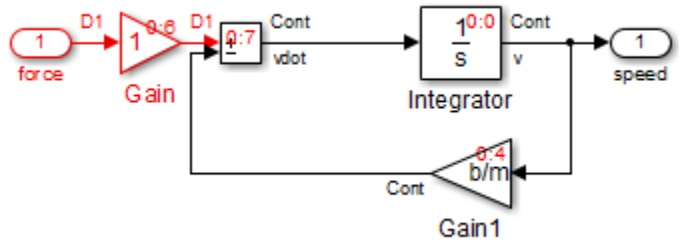
Nonvirtual Subsystems

The following model contains an atomic, nonvirtual subsystem named Discrete Cruise Controller.

When you enable the sorted order display for the root-level system, Simulink displays the sorted order of the blocks.



The Scope block in this model has the lowest sorted order, but its input depends on the output of the Car Dynamics subsystem. The Car Dynamics subsystem is virtual, so it does not have a sorted order and does not execute as an atomic unit. However, the blocks within the subsystem execute at the root level, so the Integrator block in the Car Dynamics subsystem executes first. The Integrator block sends its output to the Scope block in the root-level model, which executes second.

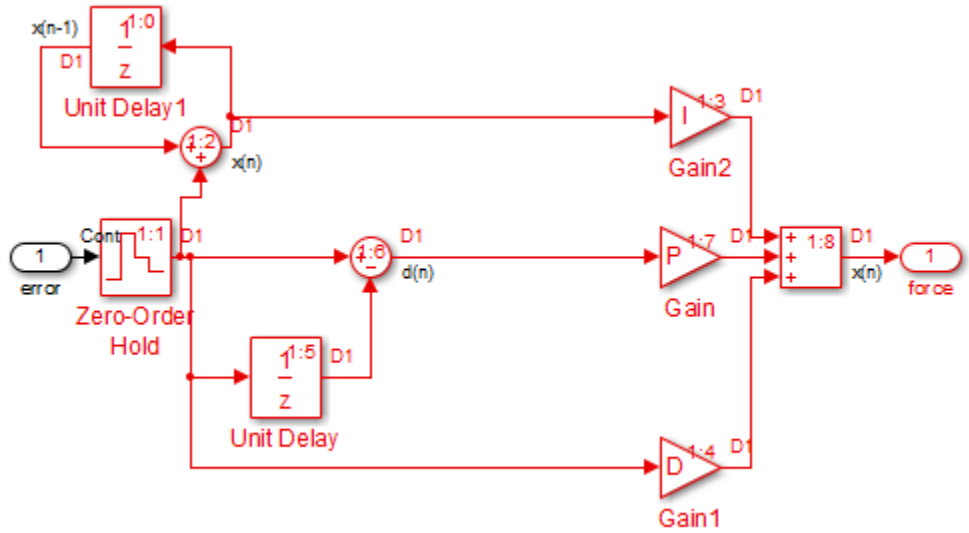


The Discrete Cruise Controller subsystem has a sorted order of `0:5`:

- `0` indicates that this atomic subsystem is part of the root level of the hierarchical system comprised of the primary system and the two subsystems.
- `5` indicates that the atomic subsystem is the sixth block that Simulink executes relative to the blocks within the root level.

The sorted order of each block inside the Discrete Cruise Controller subsystem has the form `1:`*b*, where:

- `1` is the system index for that subsystem.
- *b* is the block position in the execution order. In the Discrete Cruise Controller subsystem, the sorted order ranges from `0` to `8`.



Note: Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden subsystem block can have a system index that is different from the current system index. For example, if you select **Model Configuration Parameters > All Parameters > Conditional input branch execution**, Simulink creates hidden, nonvirtual subsystems, which can affect the sorted execution order.

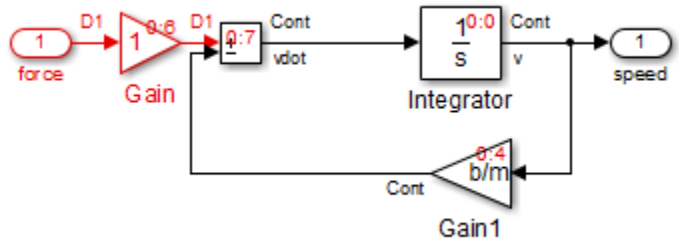
Virtual Blocks and Subsystems

Virtual blocks, such as the Mux block, exist only graphically and do not execute. Consequently, they are not part of the sorted order and do not display any sorted order notation.

Virtual subsystems do not execute as a unit, and like a virtual block, are not part of the sorted order. The blocks inside the virtual subsystem are part of the root-level system sorted order, and therefore share the system index.

In the model in "Nonvirtual Subsystems" on page 33-34, the virtual subsystem Car Dynamics does not have a sorted order. However, the blocks inside the subsystem have a sorted order in the execution context of the root-level model. The blocks have the same

system index as the root-level model. The Integrator block inside the Car Dynamics subsystem has a sorted order of `0:0`, indicating that the Integrator block is the first block executed in the context of the top-level model.

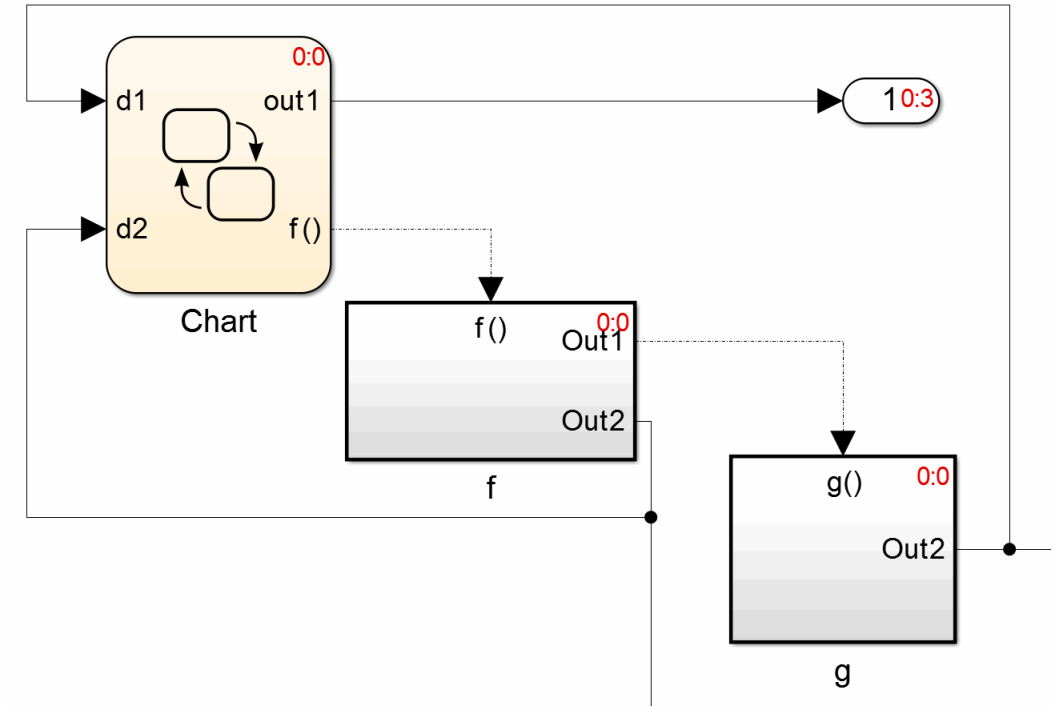


Function-Call Subsystems

Single Initiator

A function-call subsystem (or model) executes when the initiator invokes the function-call subsystem (or model) and, therefore, does not have a sorted order independent of its initiator. Specifically, for a subsystem that connects to one initiator, Simulink uses the notation `s:b`^{i}, where *s* is the index of the system that contains the initiator and `b`^{i} is the block index of the root initiator in the subsystems hierarchy.

For example, the sorted order for the subsystems f and g is `0:0`, since the sorted order of their root initiator, Chart, is `0:0`.

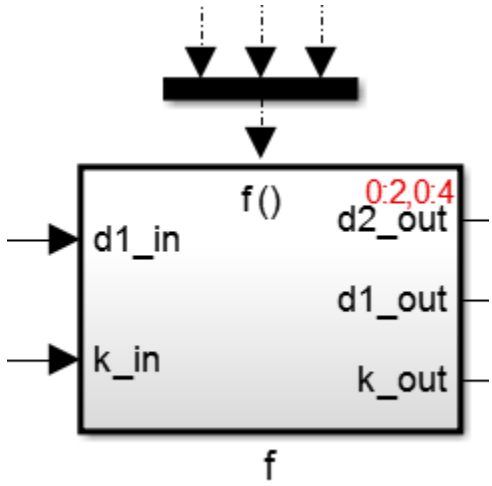


Multiple Initiators

For a function-call subsystem that connects to more than one initiator, the sorted order notation is $s{:}b^{i1}$, $s{:}b^{i2}$, ..., $s{:}b^{in}$ where n is the number of non-grounded initiators, s is the system index of the model or subsystem the block resides in, and b^{in} is the block index of the n-th root initiator in the subsystem's hierarchy.

For example, open the `sl_subsys_fncall6` model. The f subsystem has three initiators from the same level in the subsystem's hierarchy. Two are from the Stateflow chart, Chart1, and one from the Stateflow chart, Chart.

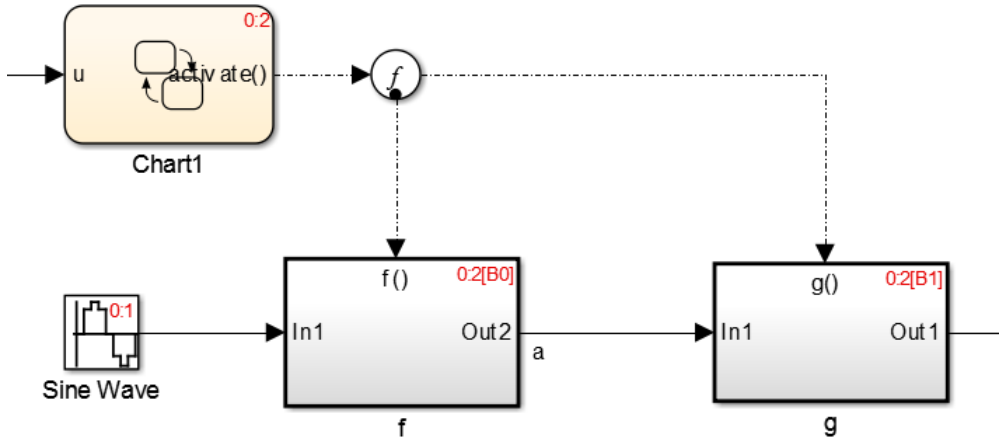
Because Chart1 has a sorted order `0:2` and Chart has a sorted order of `0:4`,the function-call subsystem f has a sorted order notation of `0:2,0:4`.



Branched Function-Call Signals

When a function-call signal is branched using a `Function-Call Split` block, Simulink displays the order in which subsystems (or models) that connect to the branches execute when the initiator invokes the function call. Simulink uses the notation $s:b^i[B_k]$ to indicate this order. s is the system index of the model or subsystem the block resides in, b^i is the block index of the root initiator in the subsystem's hierarchy, and B_k indicates that it is a branched function-call subsystem with branch index k.

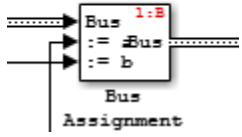
For example, open the `sl_subsys_fcncall11` model and display the sorted order. The sorted order indicates that the subsystem f (`B0`) executes before the subsystem g (`B1`).



Bus-Capable Blocks

A bus-capable block does not execute as a unit and therefore does not have a unique sorted order. Such a block displays its sorted order as `s:B` where `B` stands for bus.

For example, open the `sldemo_bus_arrays` model and display the sorted order. Open the For Each Subsystem to see that the sorted order for the Bus Assignment block appears as `1:B`.



For more information, see “Bus-Capable Blocks” on page 63-25.

How Simulink Determines the Sorted Order

Direct-Feedthrough Ports Impact on Sorted Order

To ensure that the sorted order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the

block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* port. Examples of blocks that have direct-feedthrough ports include:

- `Gain`
- `Product`
- `Sum`

Examples of blocks that have non-direct-feedthrough inputs:

- `Integrator` — Output is a function of its state.
- `Constant` — Does not have an input.
- `Memory` — Output depends on its input from the previous time step.

Rules for Sorting Blocks

To sort blocks, Simulink uses the following rules:

- If a block drives the direct-feedthrough port of another block, the block must appear in the sorted order ahead of the block that it drives.

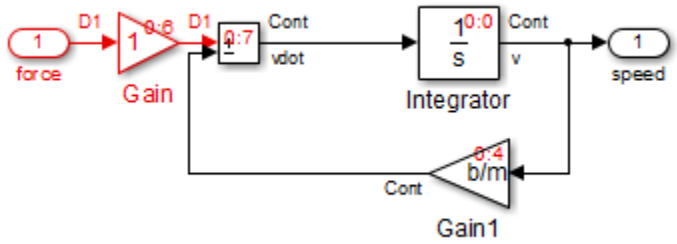
  This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block methods that require current inputs.
- Blocks that do not have direct-feedthrough inputs can appear anywhere in the sorted order as long as they precede any direct-feedthrough blocks that they drive.

  Placing all blocks that do not have direct-feedthrough ports at the beginning of the sorted order satisfies this rule. This arrangement allows Simulink to ignore these blocks during the sorting process.

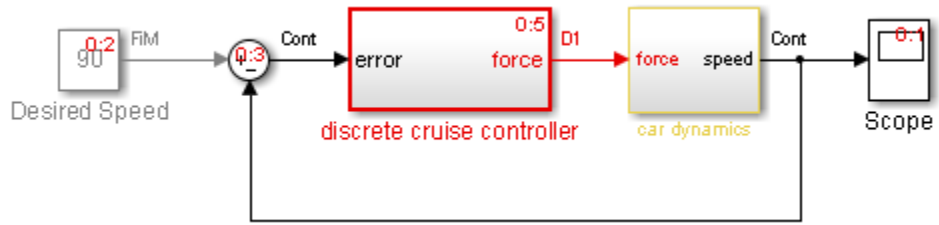
Applying these rules results in the sorted order. Blocks without direct-feedthrough ports appear at the beginning of the list in no particular order. These blocks are followed by blocks with direct-feedthrough ports arranged such that they can supply valid inputs to the blocks which they drive.

The following model, from “Nonvirtual Subsystems” on page 33-34, illustrates this result. The following blocks do not have direct-feedthrough and therefore appear at the beginning of the sorted order of the root-level system:

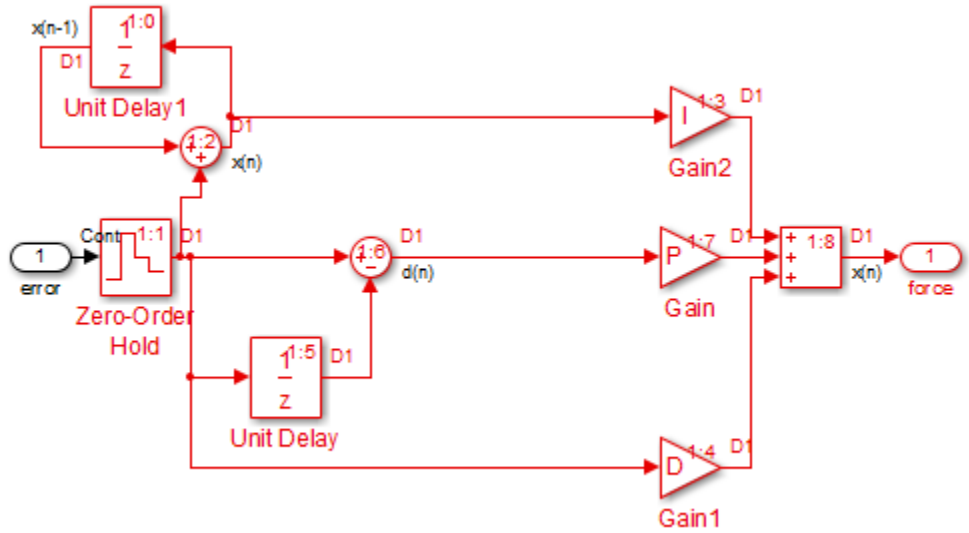
- Integrator block in the Car Dynamics virtual subsystem



- Speed block in the root-level model



Inside the Discrete Cruise Controller subsystem, all the Gain blocks, which have direct-feedthrough ports, run before the `Sum` block that they drive.



Assign Block Priorities

You can assign a priority to a nonvirtual block or to an entire subsystem. Higher priority blocks appear before lower priority blocks in the sorted order. The lower the number, the higher the priority.

- "Assigning Block Priorities Programmatically" on page 33-43
- "Assigning Block Priorities Interactively" on page 33-43

Assigning Block Priorities Programmatically

To set priorities programmatically, use the command:

```
set_param(b,'Priority','n')
```

where

- `b` is the block path.
- `n` is any valid integer. (Negative integers and 0 are valid priority values.)

Assigning Block Priorities Interactively

To set the priority of a block or subsystem interactively:

1. Right-click the block and select **Properties**.
2. On the **General** tab, in the **Priority** field, enter the priority.

Rules for Block Priorities

Simulink honors the block priorities that you specify unless they violate data dependencies. ("Block Priority Violations" on page 33-47 describes situations that cause block property violations.)

In assessing priority assignments, Simulink attempts to create a sorted order such that the priorities for the individual blocks within the root-level system or within a nonvirtual subsystem are honored relative to one another.

Three rules pertain to priorities:

- "Priorities Are Relative" on page 33-44
- "Priorities Are Hierarchical" on page 33-45
- "Lack of Priority May Not Result in Low Priority" on page 33-46

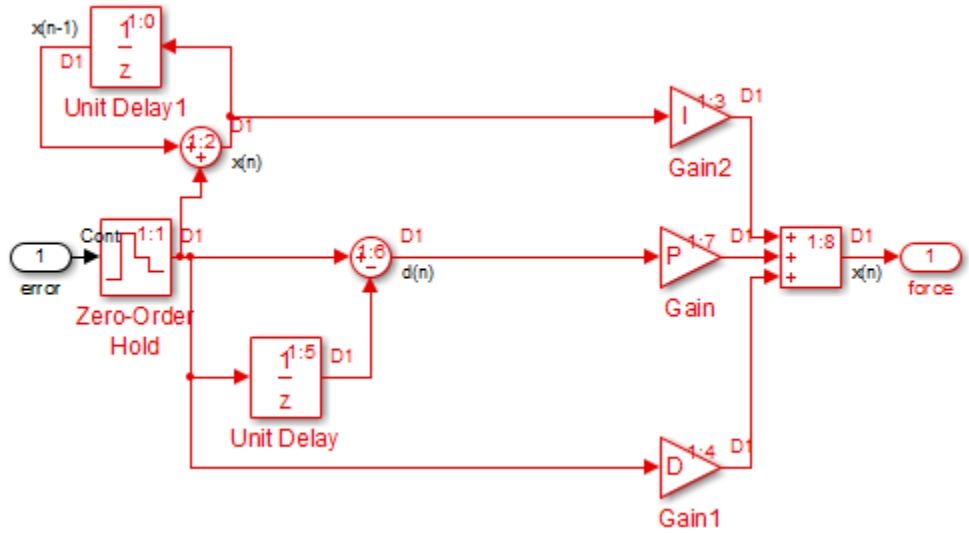
Priorities Are Relative

Priorities are relative; the priority of a block is relative to the priority of the blocks within the same system or subsystem.

For example, suppose you set the following priorities in the Discrete Cruise Controller subsystem in the model in "Nonvirtual Subsystems" on page 33-34.

Block	Priority
Gain	3
Gain1	2
Gain2	1

After updating the diagram, the sorted order for the Gain blocks is as follows.



The sorted order values of the `Gain`, `Gain1`, and `Gain2` blocks reflect the respective priorities assigned: `Gain2` has highest priority and executes before Gain1 and Gain; `Gain1` has second priority and executes after Gain2; and Gain executes after Gain1. Simulink takes into account the assigned priorities relative to the other blocks in that subsystem.

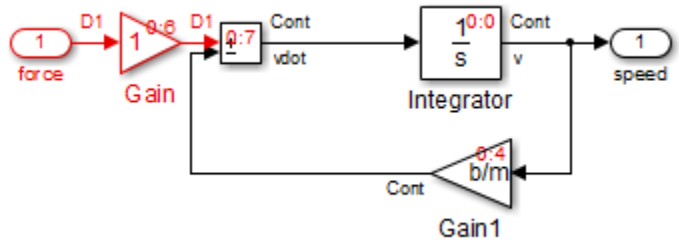
The `Gain` blocks are not the first, second, and third blocks to execute. Nor do they have consecutive sorted orders. The sorted order values do not necessarily correspond to the priority values. Simulink arranges the blocks so that their priorities are honored relative to each other.

Priorities Are Hierarchical

In the Car Dynamics virtual subsystem, suppose you set the priorities of the Gain blocks as follows.

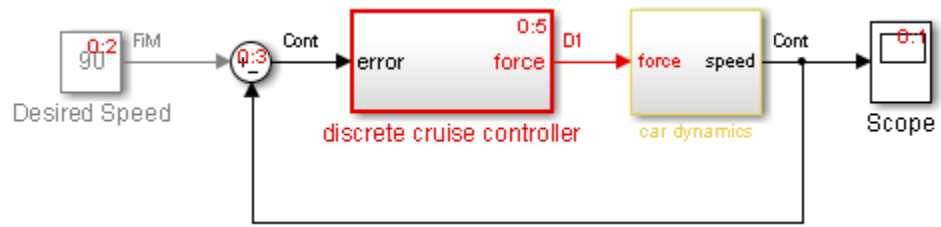
Block	Priority
Gain	2
Gain1	1

After updating the diagram, the sorted order for the Gain blocks is as illustrated. With these priorities, Gain1 always executes before Gain.



You can set a priority of 1 to one block in each of the two subsystems because of the hierarchical nature of the subsystems within a model. Simulink never compares the priorities of the blocks in one subsystem to the priorities of blocks in any other subsystem.

For example, consider this model again.



The blocks within the Car Dynamics virtual subsystem are part of the root-level system hierarchy and are part of the root-level sorted order. The Discrete Cruise Controller subsystem has an independent sorted order with the blocks arranged consecutively from 1:0 to 1:7.

Lack of Priority May Not Result in Low Priority

A lack of priority does not necessarily result in a low priority (higher sorting order) for a given block. Blocks that do not have direct-feedthrough ports execute before blocks that have direct-feedthrough ports, regardless of their priority.

If a model has two atomic subsystems, A and B, you can assign priorities of 1 and 2 respectively to A and B. This priority causes all the blocks in A to execute before any of the blocks in B. The blocks within an atomic subsystem execute as a single unit, so the subsystem has its own system index and its own sorted order.

Block Priority Violations

Simulink software honors the block priorities that you specify unless they violate data dependencies. If Simulink is unable to honor a block priority, it displays a `Block Priority Violation` diagnostic message.

As an example:

1. Open the `sldemo_bounce` model.

   Notice that the output of the Memory block provides the input to the Coefficient of Restitution Gain block.

2. Set the priority of the Coefficient of Restitution block to `1`, and set the priority of the Memory block to `2`.

   Setting these priorities specifies that the Coefficient of Restitution block execute before the Memory block. However, the Coefficient of Restitution block depends on the output of the Memory block, so the priorities you just set violate the data dependencies.

3. In the model window, enable sorted order by selecting **Format** > **Block displays** > **Sorted Order**.

4. Select **Simulation** > **Update Diagram**.

   The block priority violation warning appears in the **Diagnostic Viewer**. To open the **Diagnostic Viewer** window, click **View** > **Diagnostic Viewer**. The warning includes the priority for the respective blocks:

   ```
   Warning: Unable to honor user-specified priorities.
   'sldemo_bounce/Memory' (pri=[2]) has to execute
   before 'sldemo_bounce/Coefficient of  Restitution'
    (pri=[1]) to satisfy data dependencies
   ```

5. Remove the priorities from the Coefficient of Restitution and Memory blocks and update the diagram again to see the correct sorted order.

Access Block Data During Simulation

In this section...

"About Block Run-Time Objects" on page 33-49
"Access a Run-Time Object" on page 33-49
"Listen for Method Execution Events" on page 33-50
"Synchronizing Run-Time Objects and Simulink Execution" on page 33-51

About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see "Write Level-2 MATLAB S-Functions" in the online Simulink documentation).

Note You can use this interface even when the model is paused or is running or paused in the debugger.

The block run-time interface consists of a set of Simulink data object classes (see "Data Objects" on page 57-54) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

Access a Run-Time Object

Every nonvirtual block in a running model has a RuntimeObject parameter whose value, while the simulation is running, is a handle for the blocks' run-time object. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb,'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

Note Virtual blocks (see "Nonvirtual and Virtual Blocks" on page 33-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see "Block reduction"). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function adapt_lms.m, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's DWork vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h   = add_exec_event_listener(blk, ...
         'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's DWork vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot  = get_param(block.BlockHandle,'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2),'YData',est);
drawnow('expose');
```

Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcb,'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box on the **All Parameters** tab (see “Signal storage reuse”).

Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a `Gain` block has a **Gain** parameter, and a `Transfer Fcn` block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

To set block sample times, see “Specify Sample Time” on page 7-3.

In this section...

“Access Block Parameter Values Through Dialog Boxes” on page 34-2
“Programmatically Access Parameter Values” on page 34-3
“Specify Parameter Values” on page 34-3
“Considerations for Other Applications” on page 34-9

Access Block Parameter Values Through Dialog Boxes

To view and edit block parameter values, you can:

- Double-click the block.
- Right-click the block and select **Block Parameters**.
- Click the block. In the model, from the **Diagram** menu, select **Block Parameters**.

When you double-click `Subsystem` and `Model` blocks, the Simulink Editor opens the contents of the subsystem or the referenced model instead of the block dialog box. When you double-click a masked block, the mask dialog box opens instead of the underlying block dialog box. To open the block dialog box for these blocks, right-click the block and select **Block Parameters**.

You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see “Model Explorer Overview” on page 12-2.

Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to adjust parameter values between simulation runs, or during a simulation, when you simulate a model programmatically.

Suppose you create a model named `myModel` that contains a `Constant` block named My Constant. Next, you use the block dialog box to set the **Constant value** parameter to `15`. To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant','Value')
```

```
paramValue =

15
```

To programmatically change the value, for example to `25`, use the function `set_param`. Use the string `'25'` as the input to the function.

```
set_param('myModel/My Constant','Value','25')
```

For a list of programmatic names of block parameters, see "Block-Specific Parameters".

For more information about programmatic simulation, see "About Programmatic Simulation" on page 24-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See "Share and Reuse Block Parameter Values by Creating Variables" on page 34-12.

Specify Parameter Values

Goal	Block Parameter Value	Description

Store the parameter value in the model file.	`2.3`
	
	`[1.2 2.3 4.5; 7.9 8.7 6.5]`
	
	`2 + 3i`
		Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use `i` to specify complex values.

Goal	Block Parameter Value	Description
• Access the parameter value without having to locate the block in the model. • Change the parameter value without having to modify the model file. • Share the parameter value between blocks or between models. • Identify the parameter by a specific name when sweeping or tuning the value.	`myVar`	MATLAB variable that exists in a workspace. For more information, see "Share and Reuse Block Parameter Values by Creating Variables" on page 34-12.
• Avoid name clashes between workspace variables. • Organize parameter values using hierarchies and meaningful names. • Reduce the number of workspace variables that a model uses.	`myParam.a.SpeedVect`	Field of parameter structure. For more information, see "Organize Related Block Parameter Definitions in Structures" on page 34-20.
Use a portion of a matrix or array variable. For example, set the parameters of a `n-D Lookup Table` block.	`myMatrixParam(:,2)`	Index operation.

Goal	Block Parameter Value	Description
• Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value. • Define a system constant with custom documentation. • Create a tunable parameter in the generated code.	`myParam`	Parameter object. For more information, see "Use Parameter Objects" on page 34-6.

• Model a complicated algorithm or subroutine by using code instead of blocks.
• Reduce block population in a model.
• Use MATLAB operators and functions to perform calculations in a model.
• Write a custom MATLAB function that calculates parameter values.
	`5^3.2 - 1/3`
	
	`myParam * myOtherparam + sin(0.78*pi)`
	
	`myFun(15.23)`
		Expression or custom function.
		
		For more information, see "Use MATLAB Functions and Custom Functions" on page 34-6.

Specify a block parameter value by using a data type other than `double`.	`15.23`
	
	`single(15.23)`
	
	`myParam`
		Typed or untyped expression, numeric MATLAB variable, or parameter object.
		
		For more information about controlling parameter data types, see "Block Parameter Data Types" on page 34-49.

Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

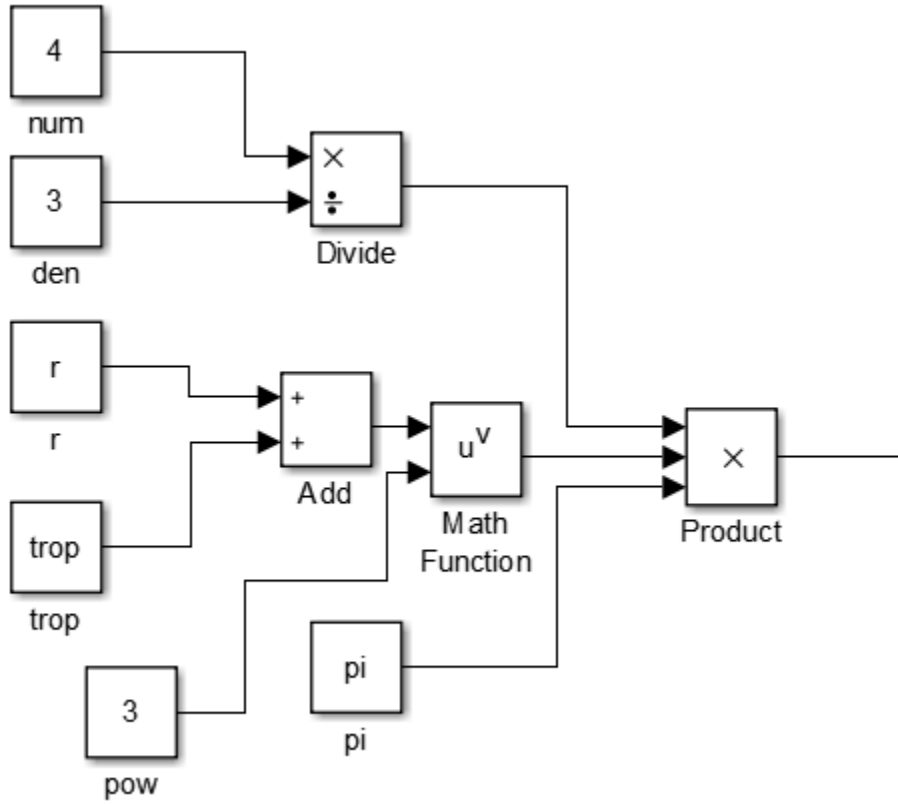
Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 57-54.

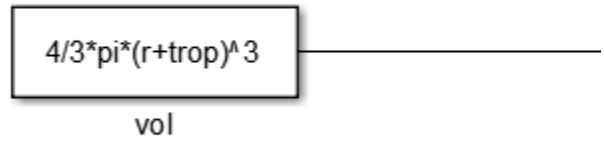
Use MATLAB Functions and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.



Instead, create a single `Constant` block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.



You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a `Gain` block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

paramFcn.m

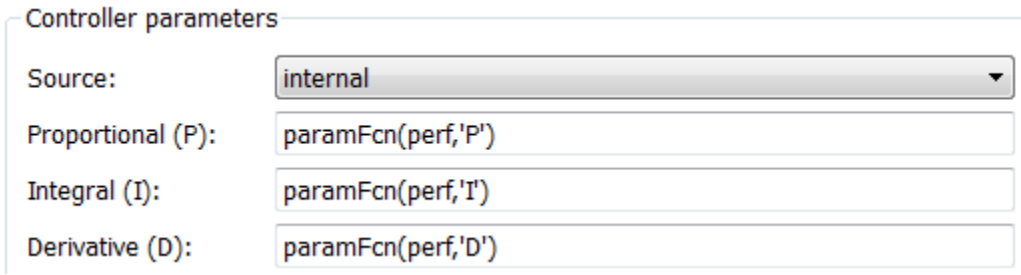
```
function paramValue = paramFcn(performance,parameter)
%PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
%value PARAMVALUE that you request using PARAMETER. Specify performance
%criteria using PERFORMANCE.

% Initialize output.
paramValue = [];

% Calculate parameter value.
switch parameter
    case 'P'
        paramValue = performance*3;
    case 'I'
        paramValue = sqrt(performance)/0.175;
    case 'D'
        paramValue = performance^0.25;

% Validation
```

You can parameterize a `PID Controller` block by using the function to set the parameter values.



Considerations for Other Applications

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	Rapid accelerator simulations, which require Simulink Coder software	Use variables or parameter objects to set block parameter values. This technique helps you to identify tunable parameters when you pass parameter sets to the executable. See "Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode" and `Simulink.BlockDiagram.buildRapidAcceleratorTarget`.
Override parameter values during testing.	Simulink Test™	Use variables or parameter objects to set block parameter values. See "Parameter Overrides".
Estimate and optimize parameter values.	Simulink Design Optimization™	Use variables or parameter objects to set block parameter values. To estimate or optimize a parameter that uses a data type other than `double`, use a parameter object to separate the value from the data type. For parameter estimation, see "Parameter Estimation". For response optimization, see "Optimize Model Response".
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See "Control Parameter Representation and Declare Tunable Parameters in the Generated Code".

Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a `Gain` block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Access the parameter value without having to locate the block in the model.
- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see "Set Block Parameter Values" on page 34-2.

Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

1. At the command prompt, create a numeric variable in the base workspace. For example, create a variable `myParam` whose value is `15.23`.

   ```
   myParam = 15.23;
   ```
2. Open a block dialog box. Set the value of the target parameter to `myParam`.
3. Set the values of parameters in the same block or in other blocks to `myParam`.

If you store the variable in the base workspace, you can use the variable in all open models. For example, if you use model referencing to segment a model into components, you can use the variable in multiple models in a model reference hierarchy.

If you store the variable in a data dictionary, you can use the variable in all of the models that are linked to the dictionary or to other dictionaries that reference the dictionary. If you link multiple models to different data dictionaries, to use a variable in more than one of the models, consider storing the variable in a single separate dictionary to which no models are linked. Then, use dictionary referencing to share the variable between the target models. Models that you link to a data dictionary cannot use variables that are in the base workspace.

Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

To create and use parameter objects in models, see “Data Objects” on page 57-54.

Control Scope of Parameter Values

The *scope* of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models,

Scope	Technique
	create a referenced dictionary. See "What Is a Data Dictionary?" on page 61-2
One model, including all subsystems in the model	Create a variable in the model workspace. See "Model Workspaces" on page 4-86.
Multiple blocks inside a subsystem, including blocks in nested subsystems	Mask the subsystem and create a mask parameter instead of a workspace variable. To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set **Permit Hierarchical Resolution** to `None`. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter. For information about subsystems, see `Subsystem`. For information about masking, see "Masking Fundamentals" on page 36-2.

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see "Organize Related Block Parameter Definitions in Structures" on page 34-20.

For basic information about how blocks use the variable names that you specify, see "Symbol Resolution" on page 4-97.

Permanently Store Workspace Variables

Variables that you create in the base workspace variables do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model *callback* is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

1. In a model that contains a `Gain` block, set the value of the **Gain** parameter to `K`.
2. At the command prompt, create a variable `K` in the base workspace.

   ```
   K = 27;
   ```

3. In the Workspace browser, right-click the variable and select **Save As**.

   To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.
4. In the dialog box, set **Save as type** to `MATLAB Script`. Set **File name** to `loadvar` and click **Save**.

   The script file `loadvar.m` appears in your current folder. You can open the file to view the command that creates the variable `K`.
5. In the model, select **File** > **Model Properties** > **Model Properties**.
6. In the **Callbacks** tab of the Model Properties dialog box, select `PreLoadFcn` as the callback that you want to define. In the **Model pre-load function** pane, enter `loadvar` and click **OK**.
7. Save the model.

The next time that you open the model, the `PreloadFcn` callback loads the variable `K` into the base workspace. You can also save the variable to a MAT-file, for example `loadvar.mat`, and set the model callback to `load loadvar`.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-70 and “Callbacks for Customized Model Behavior” on page 4-70. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 34-15.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model, consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Data for Simulink Models” on page 57-78.

Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

1. At the command prompt, create the variable `K` in the base workspace.

```
K = 27;
```

2 Save the variable to a new script file named `loadvar.m`.

```
matlab.io.saveVariablesToScript('loadvar.m','K')
```

3 Set the model callback to load the script file.

```
set_param('mymodel','PreloadFcn','loadvar')
```

4 Save the model.

```
save_system('myModel')
```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt or the Model Explorer to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use.

The Model Explorer allows you to manage variables by using a graphical interface. You can view and edit the contents of any workspace, including data dictionaries, and transfer variables from one workspace to another. To view and modify a variable whose value is a structure or array, you can launch the Variable Editor from the Model Explorer. For more information, see “Model Explorer Overview” on page 12-2 and “Workspace Variables in Model Explorer” on page 12-51.

You can also create and edit variables directly through block dialog boxes. See “Manage Variables from Block Parameter” on page 34-43.

At the command prompt, you can create variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

Target Workspace	Technique or Interface
Base workspace	Enter commands at the command prompt.

Target Workspace	Technique or Interface
Model workspace	See `Simulink.ModelWorkspace`.
Data dictionary	See "Store Data in Dictionary Programmatically" on page 61-51.

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

Design Parameter Interface for Reusable Components

You can use subsystems, model referencing, and custom block libraries to package models and blocks into components that you can reuse in other models. For guidelines to help you decide how to componentize a system, see "Componentization Guidelines" on page 15-29.

When you design a reusable component, you create the component definition, for example, as a model file if you intend to use model referencing. To use the component in one or more other models, you *instantiate* the component, for example, by adding a `Model` block to a model. Each `Model` block is an instance of the component.

You can design the component so that each instance uses different values for a block parameter. This technique allows you to reuse a block algorithm by varying only the values of block parameters.

Suppose that you create a reusable subsystem by placing it in your own custom block library. The subsystem contains a `Gain` block. You can configure the subsystem so that when you create two instances in a model, the **Gain** parameter in one of the instances uses a value, say `3.12`, while the other instance uses a different value, `5.23`.

Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a `Model` block to a model, you set the values of the arguments in the block. When you add another `Model` block, you can set different values for the same arguments.

If you have a large model with many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see "Parameterize Model References" on page 8-60. For more information about structures, see "Organize Related Block Parameter Definitions in Structures" on page 34-20.

Subsystems

If you use subsystems and custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the `Subsystem` block. When you instantiate the component again, you can set different values for the same mask parameters.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see `Subsystem`. For more information about custom block libraries, see "Create a Custom Block" on page 37-19. For more information about masks, see "Masking Fundamentals" on page 36-2. For more information about structures, see "Organize Related Block Parameter Definitions in Structures" on page 34-20.

Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable, and each field of the structure stores a numeric parameter value, reducing the number of workspace variables that you must maintain.

You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a *namespace* that prevents the field names from conflicting with each other and with other variable names in the same scope. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each parameter value.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see Structures. For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 34-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Signals” on page 63-78.

Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model `f14` uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables `Zw`, `Mw`, and `Mq` in the base workspace. To organize these variables into a single structure variable:

1. At the command prompt, open the example model.

   ```
   f14
   ```

2. At the command prompt, create the parameter structure `myGains`. Set the field values by using the values of the target variables.

   ```
   myGains.Zw = Zw;
   myGains.Mw = Mw;
   myGains.Mq = Mq;
   ```

3. In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
4. In the **Select a system** dialog box, click the node **f14** and click **OK**. Click **OK** when asked about updating the diagram.
5. In the **Contents** pane, right-click the row corresponding to the block labeled Gain1 and select **Properties**. The Gain1 block dialog box opens.
6. Change the value of the **Gain** parameter from `Mq` to `myGains.Mq` and click **OK**.
7. In the **Contents** pane, right-click the row corresponding to the Transfer Fcn.1 block and select **Properties**.
8. Change the value of the **Denominator coefficients** parameter from `[1,-Mq]` to `[1,-myGains.Mq]` and click **OK**.
9. In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables `Mw` and `Zw`. In the block dialog boxes, replace the references to the variable names according to the table.

Variable Name	Replacement Name
Mw	myGains.Mw
Zw	myGains.Zw

10 Clear the old variables.

```
clear Zw Mw Mq
```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can use the functions `Simulink.BlockDiagram.createVarStruct` and `Simulink.BlockDiagram.applyVarStruct` to migrate a model to use a single parameter structure instead of multiple workspace variables. For an example, see "Migration to Structure Parameters".

Manage Structure Variables

To create, modify, and view a variable whose value is a structure, you can use the Model Explorer whether you store the variable in the base workspace, a model workspace, or a data dictionary. To view and modify the field values in the structure, open the Variable Editor. For more information, see "Workspace Variables in Model Explorer" on page 12-51.

Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
```

```
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
    'SubsystemA',struct(...
        'Gain',Gain_SubsystemA,...
        'Offset',Offset_SubsystemA,...
        'Init',Init_SubsystemA),...
    'SubsystemB',struct(...
        'Coeffs',Coeffs_SubsystemB,...
        'Offset',Offset_SubsystemB,...
        'Init1',Init1_SubsystemB,...
        'Init2',Init2_SubsystemB)...
);
```

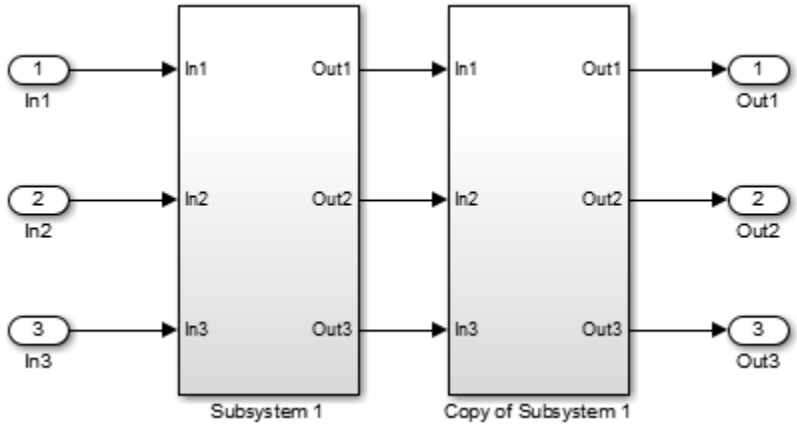
The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.



Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;

myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a `For Each Subsystem` block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 63-108.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model

argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the array as the value of the model argument in a `Model` block. Each structure in the array stores the parameter values for one instance of the referenced model.

The example model `sldemo_mdlref_datamngt` contains three instances (masked `Model` blocks) of the referenced model `sldemo_mdlref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the `Model` blocks. Since `IC1` is structurally identical to `IC2`, and `Param1` to `Param2`, you can combine these four structures into two arrays of structures.

1. Open the example parent model.

   ```
   sldemo_mdlref_datamngt
   ```

   The model creates the four `Simulink.Parameter` objects in the base workspace.
2. Open the example referenced model.

   ```
   sldemo_mdlref_counter_datamngt
   ```

   The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.
3. In the model `sldemo_mdlref_datamngt`, double-click each of the `Model` blocks, which opens the mask dialog boxes. Each mask uses a different combination of the four parameter objects from the base workspace to set the model argument values in the `Model` blocks.
4. At the command prompt, view the values of the parameter objects from the base workspace.

   ```
   Param1.Value
   IC1.Value

   ans =

        Increment: 1
       LowerLimit: -20
       UpperLimit: 20
   ```

```
ans =

            Count: 0
    OverflowState: InRange
```

The value of each parameter object is a structure. The structures in `Param2` and `IC2` have the same fields as the structures in `Param1` and `IC1` but different field values.

5 Combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;

% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.

% Delete the old objects Param1 and Param2.
clear Param1 Param2

% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

6 In the parent model, double-click each of the `Model` blocks. In the mask dialog boxes, replace the parameter values according to the table.

Previous Value	New Value
`Param1`	`Param(1)`
`IC1`	`IC(1)`
`Param2`	`Param(2)`
`IC2`	`IC(2)`

Each `Model` block sets the value of the model argument `CounterICs` by using one of the structures in the array `IC`. Similarly, each block sets the value of `CounterParams` by using one of the structures in `Param`.

Explicitly Specify Field Data Types

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);

% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.

- The shape of the entire structure. The *shape* of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

1. Create a parameter structure `myParams`.

```
myParams = struct(...
    'SubsystemA',struct(...
        'Gain',15.23,...
        'Offset',89,...
        'Init',0.59),...
    'SubsystemB',struct(...
        'Coeffs',[5.32 7.99],...
        'Offset',57,...
        'Init1',1.76,...
        'Init2',2.76)...
);
```

2. Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

   Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `slBus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

3. Rename the bus object `slBus1` as `myParamsType`.

```
myParamsType = slBus1;
clear slBus1
```

4. Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

   The `Value` property of the parameter object contains the structure.

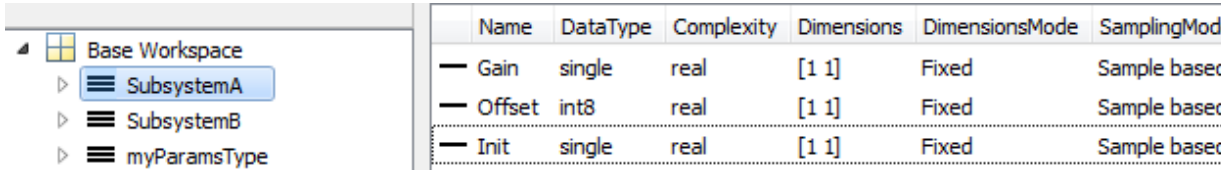
5. Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

6. Open the Bus Editor to view the bus objects.

```
buseditor
```

7. In the **Model Hierarchy** pane, click the node SubsystemA. In the **Contents** pane, set the field data types according to the figure.



8 Optionally, set the field data types for the substructure `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Manage Bus Objects with the Bus Editor” on page 63-33.

Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a `Gain` block. If you want the data type of the field to match the data type of the output signal of the block, consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

1 At the command prompt, create a `Simulink.AliasType` object that represents the data type `single`.

```
myType = Simulink.AliasType;
myType.BaseType = 'single';
```

2. In the `Gain` block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.
3. At the command prompt, open the Bus Editor.

   ```
   buseditor
   ```

4. In the **Model Hierarchy** pane, select the bus object `SubsystemA`. In the **Contents** pane, set the data type of the field `Gain` to `myType`.

Now, both the output signal of the `Gain` block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
```

```
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

Create a Structure of Constant-Valued Signals

You can use a structure in a `Constant` block to create a single bus signal that transmits multiple numeric constants. For more information, see `Constant`. For information about bus signals, see "Buses" on page 63-6.

Considerations Before Migrating to Parameter Structures

Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

To discover all of the blocks that use a variable:

1. Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
2. Right-click the variable in the Model Explorer **Contents** pane and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see "Finding Blocks That Use a Specific Variable" on page 12-54.

Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with structure parameters, see "Structure Parameters and Generated Code".

Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.
- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.
- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:

  - Field name
  - Numeric data type, such as `single` or `int32`
  - Complexity
  - Dimensions

  Suppose that you define an array of two structures.

  ```
  paramStructArray = ...
  [struct('sensor1',int16(7),'sensor2',single(9.23)) ...
   struct('sensor1',int32(9),'sensor2',single(11.71))];
  ```

  You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.
- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a `Transfer Fcn` block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 68-6.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 34-46.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 34-2.

Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to rapidly prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

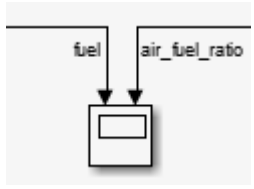
Suppose that you want to change the design value of the ideal air-to-fuel ratio from `14.6` to `17.5` to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

1. Open the example model.

   ```
   sldemo_fuelsys
   ```

2. Set the model simulation time from `2000` to `50` for a faster simulation.
3. In the model, open the `Scope` block dialog box.



4. Simulate the model. Resize the window in the `Scope` block dialog box to see all of the simulation results.

   The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately `0.9` and `1.6`. The `air_fuel_ratio` signal quickly climbs to `15` without overshoot.

5. Navigate to the target subsystem.

   ```
   open_system('sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
   ```

6. Open the block parameter dialog box for the `Constant` block labeled `rich`.
7. Change the **Constant value** parameter from `1/(14.6*0.8)` to `1/(17.5*0.8)`.
8. Similarly, change the **Constant value** parameter of the block labeled `normal` from `1/14.6` to `1/17.5`.
9. Simulate the model.

   The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

1. In the block dialog box for the block labeled `normal`, set **Constant value** to `1/mixture` and click **OK**.
2. In the block dialog box for the block labeled `rich`, set **Constant value** to `1/(mixture*0.8)` and click **Apply**.
3. Right-click the expression `1/(mixture*0.8)` and select **Create Variable** > **mixture**.
4. In the **Create New Data** dialog box, set **Value** to `17.5` and click **Create**. In the **Data properties** dialog box, click **OK**.

   The numeric variable `mixture` appears in the base workspace with value `17.5`. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

Tune Block Parameter Value During Simulation

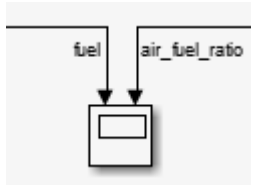
This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a `Constant` block, `Throttle Command`, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

1. Open the example model.

   ```
   sldemo_fuelsys
   ```

2. In the model, open the `Scope` block dialog box.

3. Begin a simulation.

   The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.

4. In the model, when the status bar indicates approximately `1000` (1000 seconds), click the Pause button to pause the simulation.

5. In the scope display, the **fuel** graph plots the simulation output prior to the pause time.

6. Open the block dialog box for the block labeled `Throttle Command`. Change the value of the **Output values** parameter from `[10 20 10]` to `[10 30 10]` and click **OK**.

7. Click the Step Forward button to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

   The plot of the signal `fuel` indicates a sharp increase in fuel demand that corresponds to the increased throttle command.

8. In the model, resume the simulation by clicking the Continue button.

   The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after:

- You change the value of a workspace variable.

- You use the function `set_param` to change the value of a block parameter.

For more information about updating the model diagram, see "Update Diagram and Run Simulation" on page 1-59.

Prepare for Parameter Tuning and Experimentation

- Consider using workspace variables to set block parameter values.

  To access the value of a block parameter, such as the **Constant value** parameter of a `Constant` block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

  Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of the target block parameters use the new value. For more information about accessing and setting block parameter values, see "Set Block Parameter Values" on page 34-2.
- Learn how to visualize simulation output.

  To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the `Scope` block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see "Decide How to Visualize Simulation Data" on page 27-2.
- Consider specifying value ranges for block parameters that you expect to tune during simulation.

  If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see "Control Block Parameter Value Ranges" on page 34-56.
- Learn how to control simulation duration and pace.

  A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a

specific duration or to run forever, and pause and advance the simulation when you want to. For more information about controlling simulation execution, see "Simulate a Model Interactively" on page 23-2. To programmatically control simulations, see "Control Simulation Using the set_param Command" on page 24-8.

Interactively Tune Using Dashboard Blocks

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see "Tune and Visualize Your Model with Dashboard Blocks" on page 26-71.

Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a `Sum` block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a `Discrete-Time Integrator` block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.
- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.

  1 Select the block in the model.

2. At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

   ```
   paramInfo = get_param(gcb,'DialogParameters');
   ```

   Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.

3. View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

   ```
   paramInfo.SampleTime
   ```

   ```
   ans =

           Prompt: 'Sample time:'
             Type: 'string'
             Enum: {}
       Attributes: {'read-write'  'read-only-if-compiled'  'dont-eval'}
   ```

4. Inspect the structure's `Attributes` field, whose value is a cell array of strings. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each `Model` block.

Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

  If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change

the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

To locate the definition of a variable, open a block dialog box that uses the variable. Right-click the block parameter value and select **Explore Variable**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see "Symbol Resolution" on page 4-97.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

  If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that excludes the tuning values that you want to use. To specify value ranges, see "Control Block Parameter Value Ranges" on page 34-56.

- Update the model diagram during a simulation run.

  After you tune a block parameter value during a simulation run, you must update the model diagram if you use:

  - A workspace variable to set the value of one or more block parameters. After you change the value of the variable, update the model diagram.
  - The `set_param` function to change the parameter value.

  To learn how to update a model diagram, see "Update Diagram and Run Simulation" on page 1-59.

Tunability Considerations for Other Applications

Rapid Accelerator Simulations

If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see "Tuning Runtime Parameters" on page 32-9.

Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables and `Simulink.Parameter` objects. For more information, see "Tunable Parameter Storage" in the Simulink Coder documentation.

Stateflow Charts

To debug a Stateflow chart by changing data during simulation, see "Change Data Values During Simulation".

Manage Variables from Block Parameter

In this section...
“Rename Variable” on page 34-43
“Edit Variable Value or Property” on page 34-44
“Navigate to Mask Parameter” on page 34-44
“Create Variable” on page 34-44

Rename Variable

This example shows how to rename a variable by navigating to Model Explorer from a parameter in a block dialog box.

1. Open the model `f14`. The model loads data to the MATLAB base workspace.
2. Open the block dialog box for the `Gain` block that uses variable `Mw`.
3. Right-click the expression `Mw` in the **Gain** box and select **Explore Variable**.

   Model Explorer opens with `Mw` as the selected variable in the base workspace.
4. In Model Explorer, right-click the variable `Mw` and select **Rename All**.
5. In the **Select a system** dialog box, click the name of the model `f14` to select it as the context for renaming the variable `Mw`.
6. Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.

   With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

   The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.
7. Click **OK** when asked to update the model diagram.

   Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram

update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.

9 In the block dialog, click **OK** to accept the change to the block parameter.

Edit Variable Value or Property

This example shows how to edit a variable from a parameter in a block dialog box. You can use this procedure to edit a variable made from a built-in or custom data type or from a class such as `Simulink.Parameter`.

1 Open the model `f14`. The model loads data to the MATLAB base workspace.

2 Open the block dialog box for the `Gain` block that uses the variable `Mw`.

3 Right-click the expression `Mw` in the **Gain** box and select **Open Variable**.

4 In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

Navigate to Mask Parameter

This example shows how to navigate to a mask parameter from a parameter in a block dialog box. When you explore a model that contains multiple masked subsystems and masked blocks, you can find the mask that defines a particular parameter.

1 Open the model masking_example.

2 Open the block dialog box for the `Gain` block that uses the mask parameter `m`.

3 Right-click the expression `m` in the **Gain** box and select **Open Variable**.

The mask dialog box that contains the mask parameter `m` appears.

Create Variable

This example shows how to create a variable from a parameter in a block dialog box.

1 Open the model `sldemo_fuelsys`.

2 Open the block dialog box for the `Constant` block that has value `300`.

3 In the **Constant value** box, replace the expression `300` with `myVar`.

4 Right-click the expression `myVar` and select **Create Variable**.

5 In the **Create New Data** dialog box, type `300` in the **Value** box and click **Create**.

   In the **Create New Data** dialog box you can choose the workspace to define the new variable. If a model is linked to a data dictionary, you can choose to create a variable in the dictionary.

6 In the **Data properties** dialog box, click **OK**.

Optimize, Estimate, and Sweep Block Parameter Values

When you *sweep* one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use block dialog boxes, the Model Explorer, the command prompt, or scripts to change parameter values and execute simulations.

If you want to repeatedly change the value of a block parameter, consider setting the parameter value by creating a variable in a workspace. You can use the Model Explorer or the command prompt to change the value of the variable instead of locating the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 34-34.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 34-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulation Using the sim Command” on page 24-3.

In this section...

“Capture and Visualize Simulation Results” on page 34-46
“Improve Simulation Speed” on page 34-47
“Sweep Parameter Values to Analyze System Robustness” on page 34-47
“Sweep Parameter Values to Test and Verify System” on page 34-48
“Estimate and Calibrate Model Parameters” on page 34-48
“Tune and Optimize PID and Controller Parameters” on page 34-48

Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from `Outport` blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 59-3.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 27-2.

Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. You must have Simulink Coder software to perform acceleration.

If you use the command prompt or a script to execute simulations in rapid accelerator mode, consider setting block parameter values by creating workspace variables. To specify the sweep values for a parameter, you can identify the workspace variable by its name. If you do not create a workspace variable, setting the parameter values is more difficult because the parameter does not have a unique name.

If you also have Parallel Computing Toolbox software, you can use the multiple cores of your processor to simultaneously execute simulations.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Performance”. For information about parallel simulations, see “Run Parallel Simulations” on page 24-11.

Sweep Parameter Values to Analyze System Robustness

You can sweep parameters through a range of values to analyze the robustness of a control algorithm. For example, use the Monte Carlo method to test the efficacy of a wind turbine control algorithm. You can perform many simulation runs, each of which uses a wind speed parameter that you randomly select from a distribution of possible speeds. Analysis of the simulation outputs can indicate the likelihood that the algorithm fails to control the system to your requirements.

For an example that shows how to use acceleration and parallel simulation to sweep parameter values, see “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode”.

Sweep Parameter Values to Test and Verify System

If you have Simulink Test software, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides enable you to set different parameter values for each test case. For more information, see "Parameter Overrides".

Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization software, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a *plant model*, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see "Estimate Parameters from Measured Data".

Tune and Optimize PID and Controller Parameters

If you have Simulink Control Design software, you can use PID Tuner to tune the parameters of a `PID Controller` block. For more information, see "PID Controller Tuning in Simulink".

If you have Simulink Design Optimization software, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see "Design Optimization to Meet Step Response Requirements (GUI)".

Block Parameter Data Types

When Simulink compiles a model, each of the model's blocks determines a data type for storing its parameter values that are specified using MATLAB expressions.

Most blocks use internal rules to determine the data type assigned to a specific parameter. Exceptions include the `Gain` block, whose parameter dialog box allows you to specify the data type assigned to the compiled value of its Gain parameter. You can configure your model to check whether the data type assigned to a parameter can accommodate the parameter value specified by the model. For more information, see "Data Validity Diagnostics Overview".

How Simulink Determines Parameter Data Type

Parameter Specification	Example	Effective Parameter Data Type
Numeric value	`15.3`	The block determines the parameter data type.
Nontunable expression	`1:K`	The block determines the parameter data type.
Variable with double-precision value	`K = 5`	The block determines the parameter data type.
Variable with explicit data type	`K = int8(5)`	The parameter uses the specified data type. However, the block can require a different data type, such as when you specify a type in a `Gain` block dialog box by using the **Parameter Attributes** tab. The block casts the parameter to the required type. In the generated code, the parameter uses the specified data type if the parameter is tunable.
Parameter object	`K = Simulink.Parameter(10.23)`	The parameter object first casts the specified value, `10.23`, to

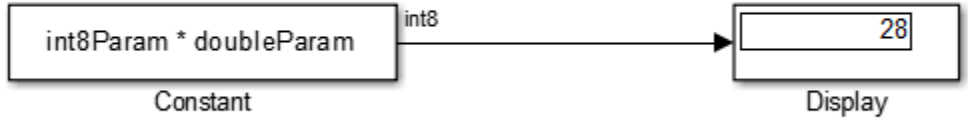
Parameter Specification	Example	Effective Parameter Data Type
	`K.DataType = 'single'`	the specified type, `single`. Then, if the block requires a different data type, it casts the result to the required type.

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a `Constant` block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```



The `Constant` block determines the data type of the **Constant value** parameter using these steps:

1. Each parameter object casts the specified numeric value to the specified data type.

Parameter object	Data type	Numeric value	Result
`int8Param`	`int8`	`3`	`int8(3)`
`doubleParam`	`double`	`9.36`	`double(9.36)`

2. The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

Display Parameter Data Type

You can use `get_param` to find the system and block parameter values for your model. See "Model Parameters" and "Common Block Properties" for arguments `get_param` accepts.

The model's signal attributes and parameter expressions must be evaluated before some parameters are properly reported. This evaluation occurs during the simulation compilation phase. Alternatively, you can compile your model without first running it, and then obtain parameter information. For instance, to access the port width, data types, and dimensions of the blocks in your model, enter the following at the command prompt:

```
modelname([],[],[],'compile')
q=get_param(gcb,'PortHandles');
get_param(q.Inport,'CompiledPortDataType')
get_param(q.Inport,'CompiledPortWidth')
get_param(q.Inport,'CompiledPortDimensions')
modelname([],[],[],'term')
```

Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and Fixed-Point Designer to calculate best-precision scaling for tunable block parameters. A block parameter or `Simulink.Parameter` object is *tunable* if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify value range information for the parameter. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.

- Configure individual block parameters or `Simulink.Parameter` objects to calculate their own scaling.

  When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model. However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types and scaling, see "Fixed-Point Numbers in Simulink".

To specify value ranges for tunable block parameters and parameter objects, see "Control Block Parameter Value Ranges" on page 34-56.

To learn how to use the Data Type Assistant to apply data types to parameters and signals, see "Specify Data Types Using Data Type Assistant" on page 57-40.

For basic information about tunable parameter representation in the generated code, see "Control Parameter Representation and Declare Tunable Parameters in the Generated Code".

Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use `Simulink.Parameter` objects instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

  If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.
- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the

corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see "Control Field Data Types and Characteristics by Creating Parameter Object" on page 34-27.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:

  - Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
  - `Simulink.Parameter` model arguments in a model workspace.

    Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

    Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in `Model` blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.
  - Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale `Simulink.Parameter` objects, see "Autoscale Simulink.Parameter Objects".

Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or parameter object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a `Simulink.Parameter`

object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

1. On the **Data Types** tab of an `n-D Lookup Table` block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.
2. Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
3. If you use a tunable `Simulink.Parameter` object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

1. At the command prompt, create a parameter object in the base workspace whose value is `15.25`.

   ```
   myParam = Simulink.Parameter(15.25);
   ```

2. In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.

3. Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.
4. Set **Data type** to `fixdt(0,16,0)`.
5. Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

   The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a `Gain` block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Set **Parameter data type** to an inherited data type such as `Inherit: Inherit from 'Gain'` so that the block parameter uses the same data type as the parameter object.

Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see "Control Parameter Data Types in the Generated Code".

- "Data Validity Diagnostics Overview"
- "Tune and Experiment with Block Parameter Values" on page 34-34

Control Block Parameter Value Ranges

When you develop a model for other users, you can protect your design by preventing your users from setting block parameter values outside ranges that you specify. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer software enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see "Set Block Parameter Values" on page 34-2.

In this section...

"Specify Block Parameter Value Ranges" on page 34-56

"Restrict Allowed Values for Block Parameters" on page 34-57

"Specify Range Information for Tunable Fixed-Point Parameters" on page 34-58

Specify Block Parameter Value Ranges

You can specify value ranges for some block parameters by using other parameters of the same block. For example, you can control the value range of the **Gain** parameter of a `Gain` block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as `n-D Lookup Table` and `PID Controller`, use the **Data Types** tab of the block dialog box.

To specify value ranges for the parameters of any block, consider using `Simulink.Parameter` objects to set the parameter values. You can specify the range information in the object instead of the block by using the `Min` and `Max` properties.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a `Gain` block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify

in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see “Data Objects” on page 57-54.

Specify Valid Range Information

The minimum and maximum values that you specify for a parameter must evaluate to a finite, scalar, real number that uses the data type `double`. For example, you can set the **Parameter minimum** parameter of a `Gain` block to a literal number such as `15.23`, or to the name of a workspace variable whose value is `15.23`. Use a workspace variable to apply the same minimum or maximum to multiple block parameters. However, you cannot use variables to set the `Min` or `Max` properties of a `Simulink.Parameter` object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

Specify Range Information for Nonscalar Parameters

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a parameter object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 34-27.

Specify Range Information for Complex-Valued Parameters

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

Restrict Allowed Values for Block Parameters

To protect your design by preventing your users from setting block parameter values outside of a design range, you can specify the range information by using other

parameters of the same block. If your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a `Simulink.Parameter` object to set the value of the target parameter. Use the properties of the object to specify the range information. This technique helps you to specify range information for a variable that you use to set multiple block parameter values.

Specify Range Information for Tunable Fixed-Point Parameters

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 34-51. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges Using Design Ranges for Simulink.Parameter Objects”.

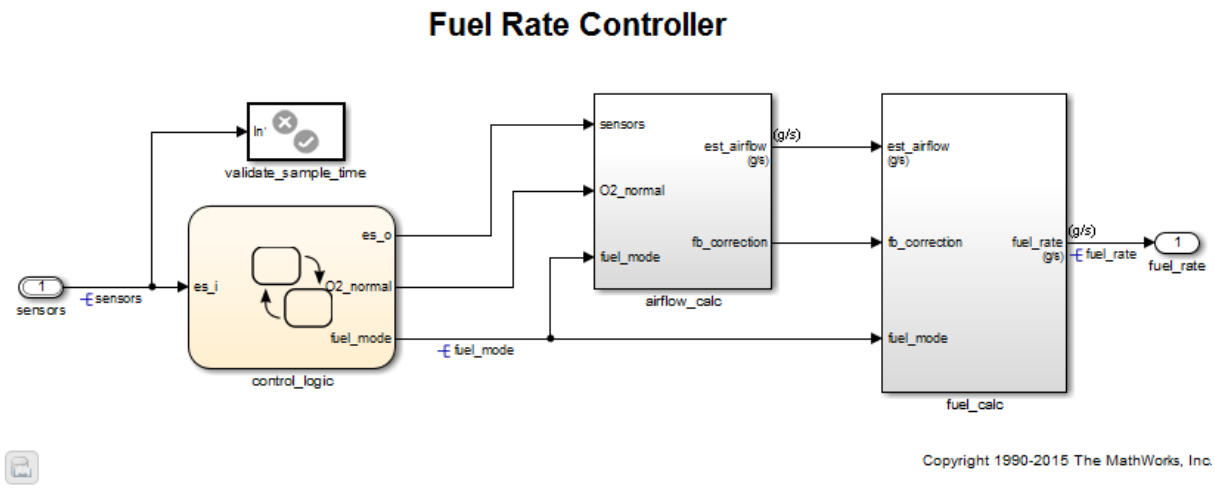
Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open this example model:

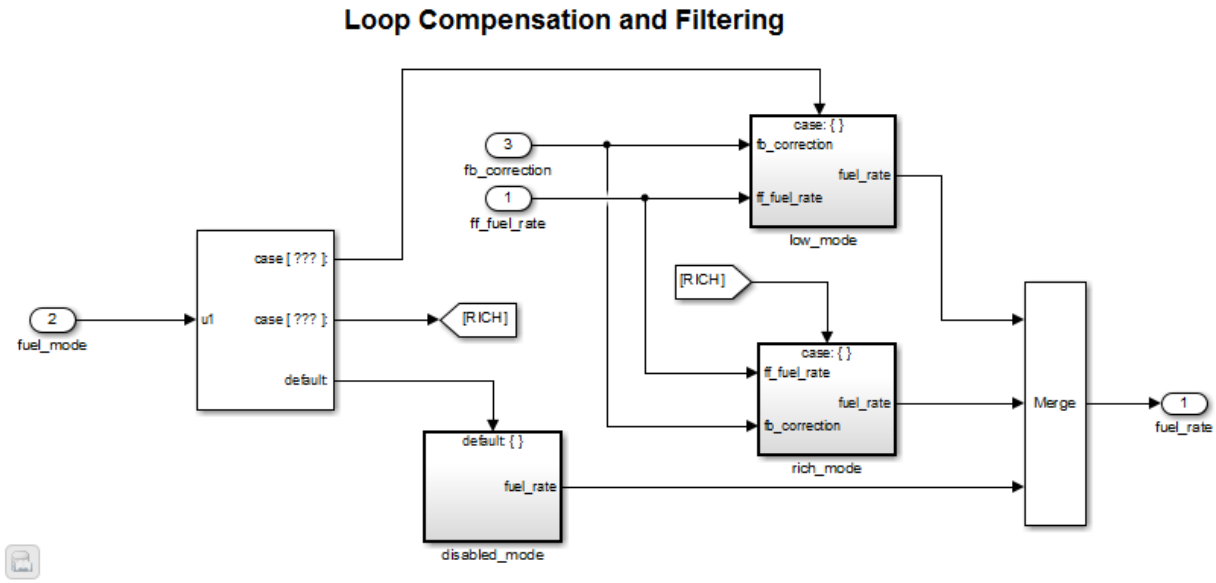
```
open_system('sldemo_fuelsys_dd_controller')
```



This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

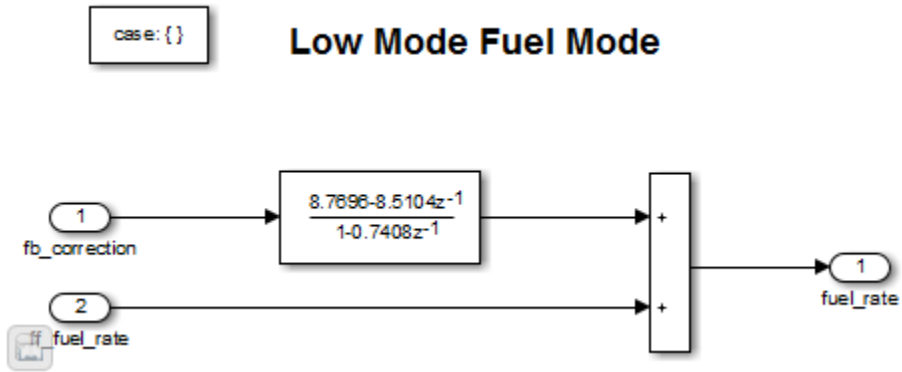
```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation'])
```



This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation/low_mode'])
```



The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/low_mode/Discrete Filter'];
```

```
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock,'Numerator'));
params.richNumerator = eval(get_param(richBlock,'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock,'Numerator','params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock,'Numerator','params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index `2`.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

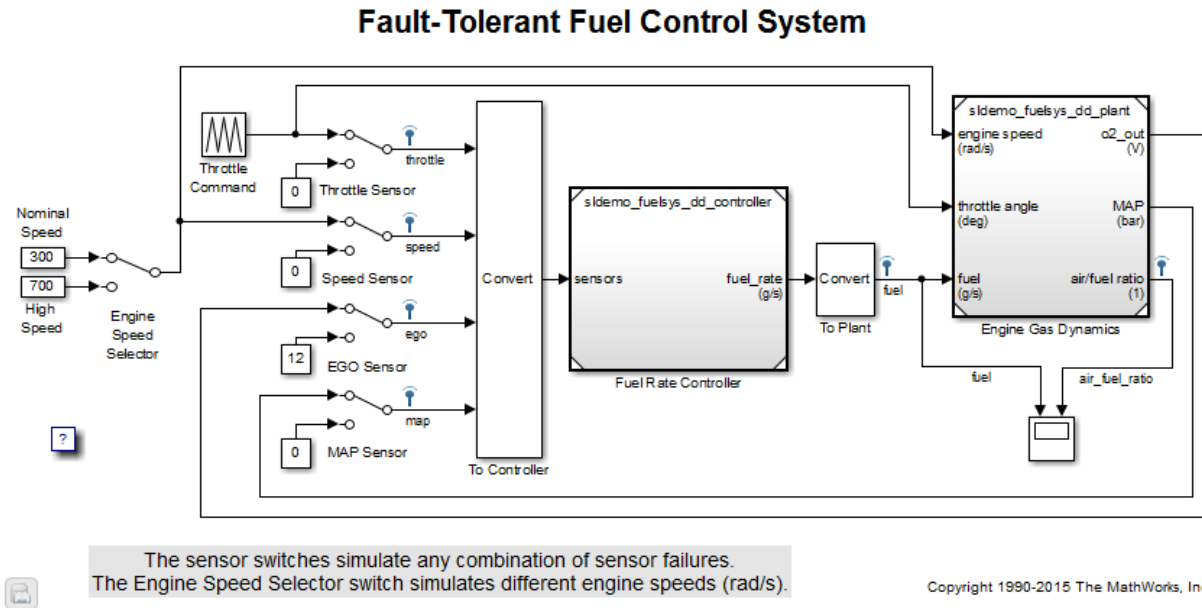
```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see "Enumerations in Data Dictionary".

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```



Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to `Storage Class`.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj,'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,params);

tempEntryObj = getEntry(sectObj,'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
```

```
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
  Weak = 1,                            /* Default value */
  Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
  real32_T lowNumerator[2];
  real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
```

```
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
    '/* Block signals (auto storage) */',1,0)

FilterCoeffs Ctrl = Aggressive;        /* Variable: Ctrl
                                        * Referenced by:
                                        *   '<S12>/Discrete Filter'
                                        *   '<S13>/Discrete Filter'
                                        */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file,'/* Exported block parameters */',...
    '/* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
  }, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
  } } ;                                /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

```
rtwdemodbtype(file,...
    'fuel_rate = ','rtDWork.DiscreteFilter_states_g) + rtb_Product2;',1,1)

    fuel_rate = (params[Ctrl - 1].lowNumerator[0] * rtb_MultiportSwitch +
                 params[Ctrl - 1].lowNumerator[1] *
                 rtDWork.DiscreteFilter_states_g) + rtb_Product2;
```

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

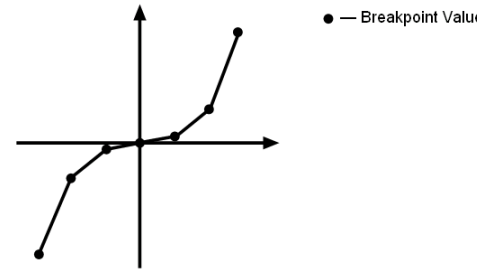
About Lookup Table Blocks

A *lookup table* block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a "lookup" operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function $y = x^3$. The lookup table defines its output (y) data discretely over the input (x) range `[-3, 3]`. The following table and graph illustrate the input/output relationship:

x	-3	-2	-1	0	1	2	3
y	-27	-8	-1	0	1	8	27

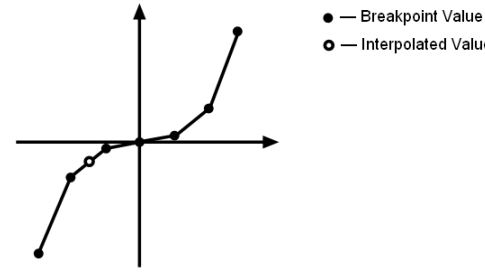


An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's x values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest data points (-2, -8) and (-1, -1) to estimate and return a value of -4.5.

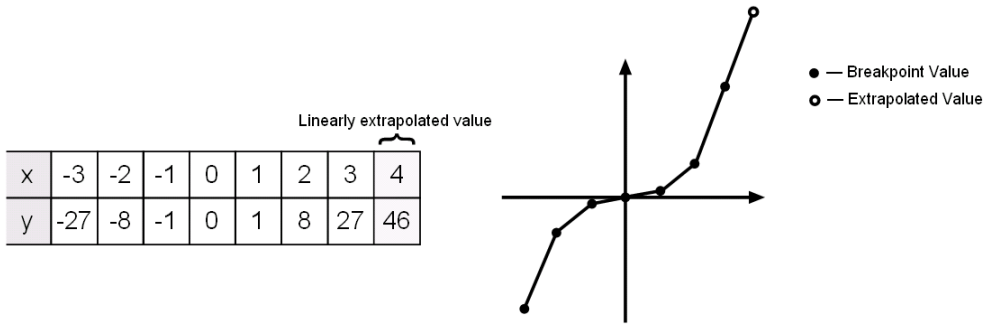
Linearly interpolated value

x	-3	-2	-1.5	-1	0	1	2	3
y	-27	-8	-4.5	-1	0	1	8	27



Similarly, although the lookup table does not include data for x values beyond the range of `[-3, 3]`, the block can extrapolate values using a pair of data points at either end

of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points (2, 8) and (3, 27) to estimate an output value of 46.



Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

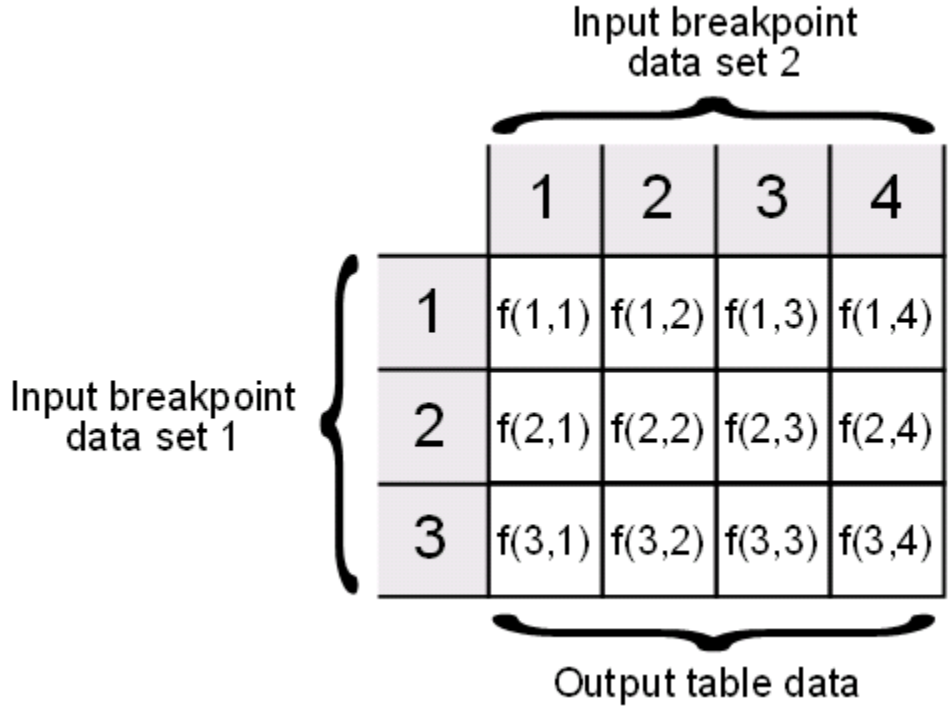
Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or *breakpoint data sets* and an array, referred to as *table data*, constitute the lookup table.



Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

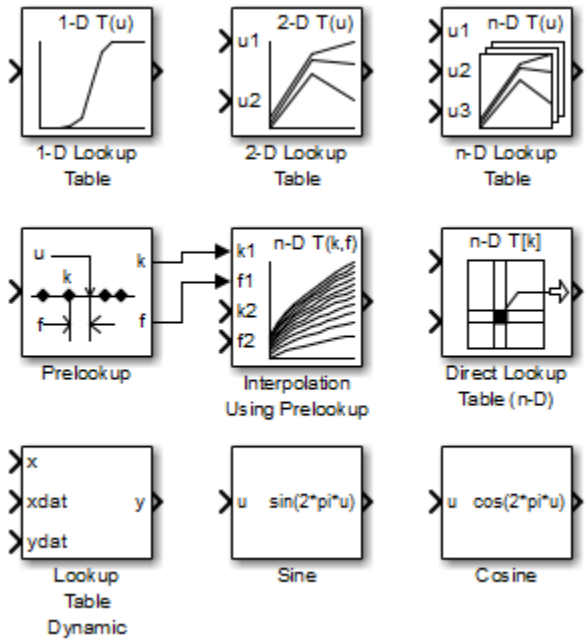
Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.



The following table summarizes the purpose of each block in the library.

Block Name	Description
`1-D Lookup Table`	Approximate a one-dimensional function.
`2-D Lookup Table`	Approximate a two-dimensional function.
`n-D Lookup Table`	Approximate an N-dimensional function.
`Prelookup`	Compute index and fraction for Interpolation Using Prelookup block.
`Interpolation Using Prelookup`	Use precalculated index and fraction values to accelerate approximation of N-dimensional function.
`Direct Lookup Table (n-D)`	Index into an N-dimensional table to retrieve the corresponding outputs.

Block Name	Description
`Lookup Table Dynamic`	Approximate a one-dimensional function using a dynamically specified table.
Sine	Use a fixed-point lookup table to approximate the sine wave function.
`Cosine`	Use a fixed-point lookup table to approximate the cosine wave function.

Guidelines for Choosing a Lookup Table

In this section...
"Data Set Dimensionality" on page 35-8
"Data Set Numeric and Data Types" on page 35-8
"Data Accuracy and Smoothness" on page 35-8
"Dynamics of Table Inputs" on page 35-9
"Efficiency of Performance" on page 35-9
"Summary of Lookup Table Block Features" on page 35-10

Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the `1-D Lookup Table` or `Lookup Table Dynamic` block. If you are approximating a two-dimensional function, consider the `2-D Lookup Table` block. Blocks such as the `n-D Lookup Table` and `Direct Lookup Table (n-D)` allow you to approximate a function of *N* variables.

Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the `Direct Lookup Table (n-D)`, `1-D Lookup Table`, `2-D Lookup Table`, and `n-D Lookup Table` blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to `double` and `single` data types.

Note: For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation

and extrapolation, improving the accuracy of values that fall between or outside of the table data, respectively. For instance, the `Lookup Table Dynamic` block performs linear interpolation and extrapolation, while the `n-D Lookup Table` block performs either linear or cubic spline interpolation and extrapolation. In contrast, the `Direct Lookup Table (n-D)` block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the `Prelookup` block with the `Interpolation Using Prelookup` block.

Dynamics of Table Inputs

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The `1-D Lookup Table`, `2-D Lookup Table`, `n-D Lookup Table`, and `Prelookup` blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the `Prelookup` block with the `Interpolation Using Prelookup` block.

Efficiency of Performance

When the efficiency with which lookup tables operate is important, consider using the `Prelookup` block with the `Interpolation Using Prelookup` block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the `Interpolation Using Prelookup` block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

Enter Breakpoints and Table Data

In this section...
"Entering Data in a Block Parameter Dialog Box" on page 35-12
"Entering Data in the Lookup Table Editor" on page 35-12
"Entering Data Using Inports of the Lookup Table Dynamic Block" on page 35-14

Entering Data in a Block Parameter Dialog Box

This example shows how to populate a `1-D Lookup Table` block using the parameter dialog box. The lookup table in this example approximates the function $y = x^3$ over the range `[-3, 3]`.

1. Copy a `1-D Lookup Table` block from the Lookup Tables block library to a Simulink model.
2. In the 1-D Lookup Table block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:
   - Set **Number of table dimensions** to `1`.
   - Set **Table data** to `[-27 -8 -1 0 1 8 27]`.
3. Enter the breakpoint data set using either of two methods:
   - To specify evenly spaced data points, set **Breakpoint specification** to `Even spacing`. Set **First point** to `-3` and **Spacing** to `1`. The block calculates the number of evenly spaced breakpoints based on the table data.
   - To specify breakpoint data explicitly, set **Breakpoint specification** to `Explicit values` and set **Breakpoints 1** to `[-3:3]`.

Entering Data in the Lookup Table Editor

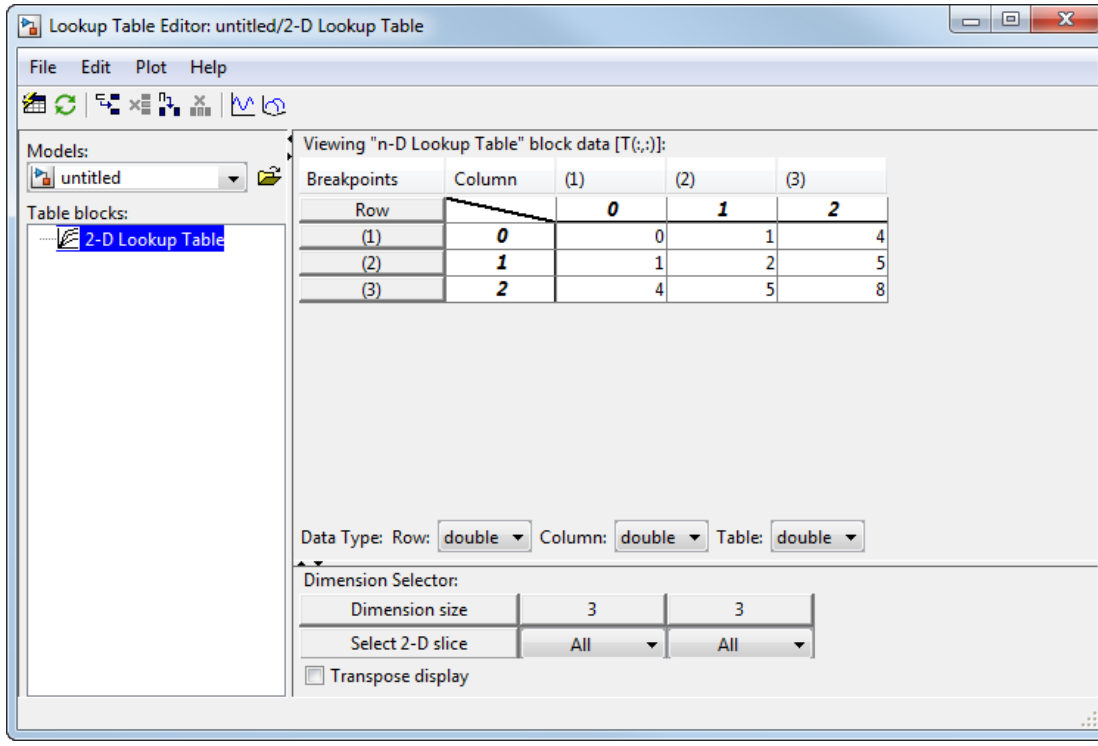
Use the following procedure to populate a `2-D Lookup Table` block using the Lookup Table Editor. In this example, the lookup table approximates the function $z = x^2 + y^2$ over the input ranges `x = [0, 2]` and `y = [0, 2]`.

1. Copy a `2-D Lookup Table` block from the Lookup Tables block library to a Simulink model.

2. Open the Lookup Table Editor by selecting **Lookup Table Editor** from the Simulink **Edit** menu or by clicking **Edit table and breakpoints** on the dialog box of the `2-D Lookup Table` block.
3. Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.

   - In the cells associated with the **Row Breakpoints**, enter each of the values `[0 1 2]`.
   - In the cells associated with the **Column Breakpoints**, enter each of the values `[0 1 2]`.
   - In the table data cells, enter the values in the array `[0 1 4; 1 2 5; 4 5 8]`.

   The Lookup Table Editor looks like this:



4 In the Lookup Table Editor, select **File** > **Update Block Data** to update the data in the `2-D Lookup Table` block.

5 Close the Lookup Table Editor.

Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a `Lookup Table Dynamic` block using that block's inports. In this example, the lookup table approximates the function $y = 3x^2$ over the range `[0, 10]`.

1 Copy a `Lookup Table Dynamic` block from the Lookup Tables block library to a Simulink model.

2 Copy the blocks needed to implement the equation $y = 3x^2$ to the Simulink model:

- One `Constant` block to define the input range, from the Sources library
- One `Math Function` block to square the input range, from the Math Operations library
- One `Gain` block to multiply the signal by 3, also from the Math Operations library

3 Assign the following parameter values to the Constant, Math Function, and Gain blocks using their dialog boxes:

Block	Parameter	Value
Constant	**Constant value**	`0:10`
Math Function	**Function**	`square`
Gain	**Gain**	`3`

4 Input the breakpoint data set to the `Lookup Table Dynamic` block by connecting the outport of the Constant block to the inport of the `Lookup Table Dynamic` block labeled **xdat**. This signal is the input breakpoint data set for x.

5 Input the table data to the `Lookup Table Dynamic` block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the inport of the `Lookup Table Dynamic` block labeled **ydat**. This signal is the table data for y.

Characteristics of Lookup Table Data

In this section...
"Sizes of Breakpoint Data Sets and Table Data" on page 35-16
"Monotonicity of Breakpoint Data Sets" on page 35-17
"Representation of Discontinuities in Lookup Tables" on page 35-17
"Formulation of Evenly Spaced Breakpoints" on page 35-19

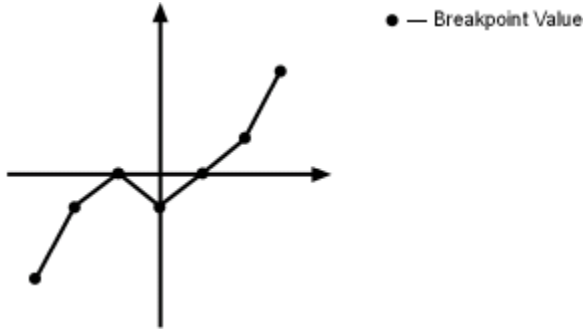
Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

```
Vector of input values:   [-3 -2 -1  0 1 2 3]
Vector of output values:  [-3 -1  0 -1 0 1 3]
```



In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

```
Row index input values:    [1 2 3]
Column index input values: [1 2 3 4]
Table data:                [11 12 13 14; 21 22 23 24; 31 32 33 34]
```

	1	2	3	4
1	11	12	13	14
2	21	22	23	24
3	31	32	33	34

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be *strictly monotonically increasing*, that is, each successive element is greater than its preceding element. For example, the vector

```
A = [0  0.5  1  1.9  2.1  3]
```

is a valid breakpoint data set as each element is larger than its predecessors.

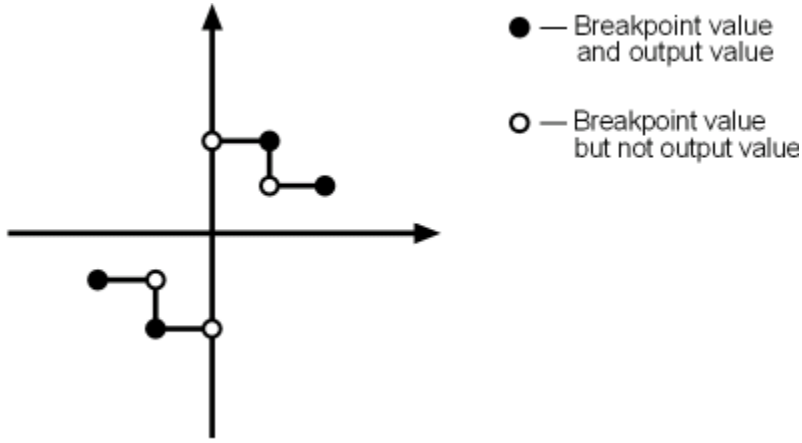
Note: Although a breakpoint data set is strictly monotonic in `double` format, it might not be so after conversion to a fixed-point data type.

Representation of Discontinuities in Lookup Tables

You can represent discontinuities in lookup tables that have monotonically increasing breakpoint data sets. To create a discontinuity, repeat an input value in the breakpoint data set with different output values in the table data. For example, these vectors

of input (*x*) and output (*y*) values associated with a 1-D lookup table create the step transitions depicted in the plot that follows.

```
Vector of input values:   [-2 -1 -1  0 0 1 1 2]
Vector of output values:  [-1 -1 -2 -2 2 2 1 1]
```



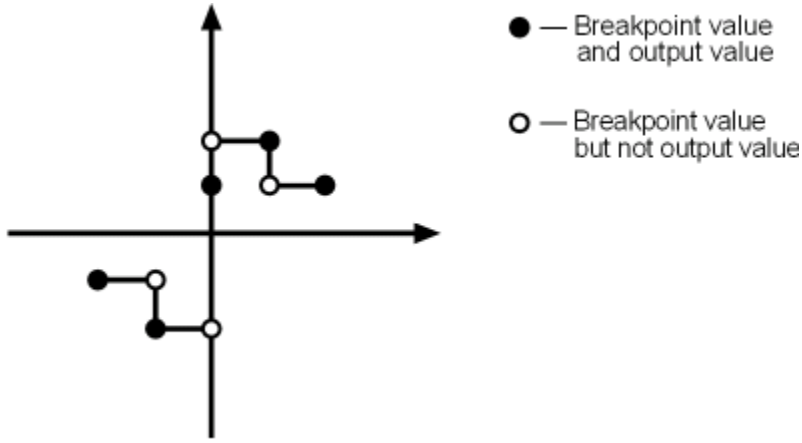
This example has discontinuities at $x = -1$, 0, and +1.

When there are two output values for a given input value, the block chooses the output according to these rules:

- If the input signal is less than zero, the block returns the output value associated with the last occurrence of the input value in the breakpoint data set. In this example, if the input is –1, *y* is –2, marked with a solid circle.
- If the input signal is greater than zero, the block returns the output value associated with the first occurrence of the input value in the breakpoint data set. In this example, if the input is 1, *y* is 2, marked with a solid circle.
- If the input signal is zero and there are two output values specified at the origin, the block returns the average of those output values. In this example, if the input is 0, *y* is 0, the average of the two output values –2 and 2 specified at $x = 0$.

When there are three points specified at the origin, the block generates the output associated with the middle point. The following example demonstrates this special rule.

```
Vector of input values:   [-2 -1 -1  0 0 0 1 1 2]
Vector of output values:  [-1 -1 -2 -2 1 2 2 1 1]
```



In this example, three points define the discontinuity at the origin. When the input is 0, *y* is 1, the value of the middle point.

You can apply this same method to create discontinuities in breakpoint data sets associated with multidimensional lookup tables.

Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

Formulation	Example	When to Use This Formulation
`[first_value:spacing:last_value]`	`[10:10:200]`	The lookup table does *not* use `double` or `single`.
`first_value + spacing * [0: (last_value-first_value)/spacing]`	`1 + (0.02 * [0:450])`	The lookup table uses `double` or `single`.

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for `double` and `single`. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see "Summary of Lookup Table Block Features" on page 35-10.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- "Effects of Spacing on Speed, Error, and Memory Usage" in the Fixed-Point Designer documentation
- "Identify questionable fixed-point operations" in the Simulink Coder documentation

---

Tip Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

Methods for Estimating Missing Points

In this section...
"About Estimating Missing Points" on page 35-21
"Interpolation Methods" on page 35-21
"Extrapolation Methods" on page 35-22
"Rounding Methods" on page 35-23
"Example Output for Lookup Methods" on page 35-24

About Estimating Missing Points

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- `Flat` — Disables interpolation and uses the rounding operation titled `Use Input Below`. For more information, see "Rounding Methods" on page 35-23.
- `Nearest` — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- `Linear` — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input.
- `Cubic spline` — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.

Note: The `Lookup Table Dynamic` block does not let you select an interpolation method. The `Interpolation-Extrapolation` option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces the smoothest results.

Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- `Clip` — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- `Linear` — If the interpolation method is `Linear`, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is `Cubic spline`, this extrapolation method fits a linear surface using the slope of the interpolant at the first or last break point, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.
- `Cubic spline` — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

Note: The `Lookup Table Dynamic` block does not let you select an extrapolation method. The `Interpolation-Extrapolation` option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

In addition to these methods, some lookup table blocks, such as the `n-D Lookup Table` block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or

an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

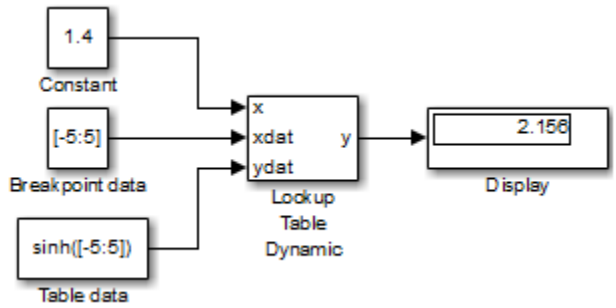
Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the `Lookup Table Dynamic` block lets you select one of the following rounding methods:

- `Use Input Nearest` — Returns the output value corresponding to the nearest input value.
- `Use Input Below` — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- `Use Input Above` — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

Example Output for Lookup Methods

In the following model, the `Lookup Table Dynamic` block accepts a vector of breakpoint data given by `[-5:5]` and a vector of table data given by `sinh([-5:5])`.



The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
`Interpolation-Extrapolation`	`1.4`	`2.156`	N/A
	`5.2`	`83.59`	N/A
`Interpolation-Use End Values`	`1.4`	`2.156`	N/A
	`5.2`	`74.2`	The block uses the value for `sinh(5.0)`.
`Use Input Above`	`1.4`	`3.627`	The block uses the value for `sinh(2.0)`.
	`5.2`	`74.2`	The block uses the value for `sinh(5.0)`.
`Use Input Below`	`1.4`	`1.175`	The block uses the value for `sinh(1.0)`.
	`-5.2`	`-74.2`	The block uses the value for `sinh(-5.0)`.
`Use Input Nearest`	`1.4`	`1.175`	The block uses the value for `sinh(1.0)`.

- "Edit Lookup Tables" on page 35-26
- "Guidelines for Choosing a Lookup Table" on page 35-8

Edit Lookup Tables

In this section...
“Edit N-Dimensional Lookup Tables” on page 35-26
“Edit Custom Lookup Table Blocks” on page 35-28

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

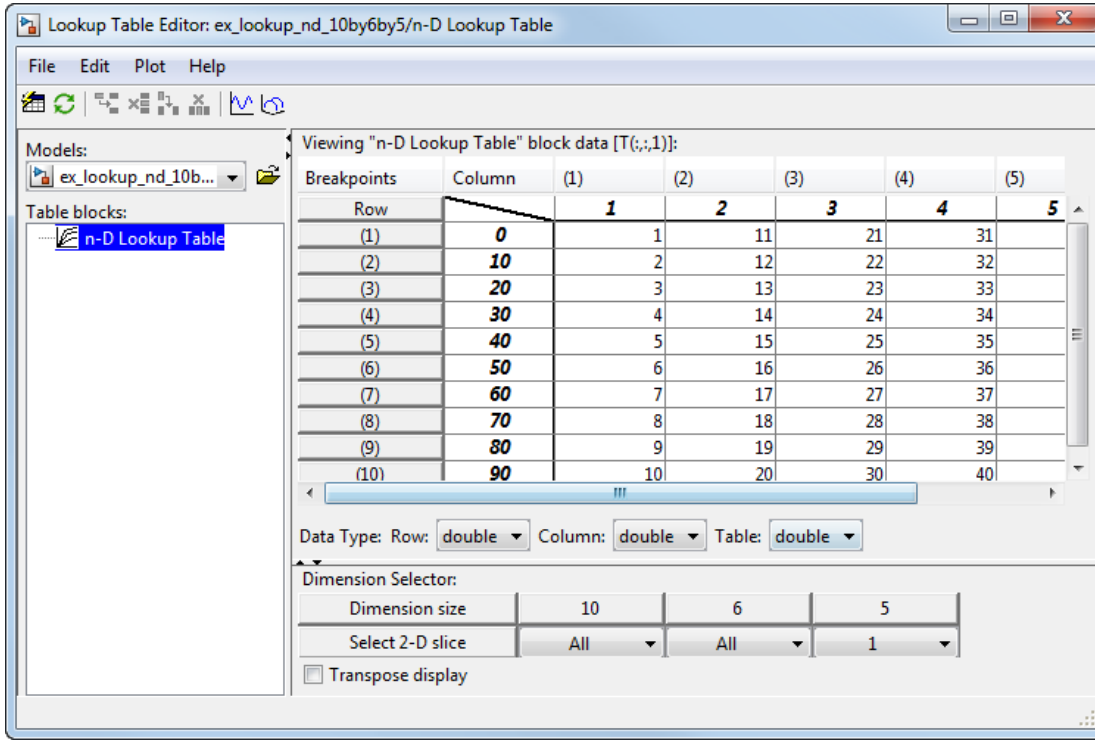
To edit the lookup table in a block:

1. Open the subsystem that contains the lookup table block.
2. Open the lookup table block’s dialog box.
3. In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.



The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-N array of controls, where N is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

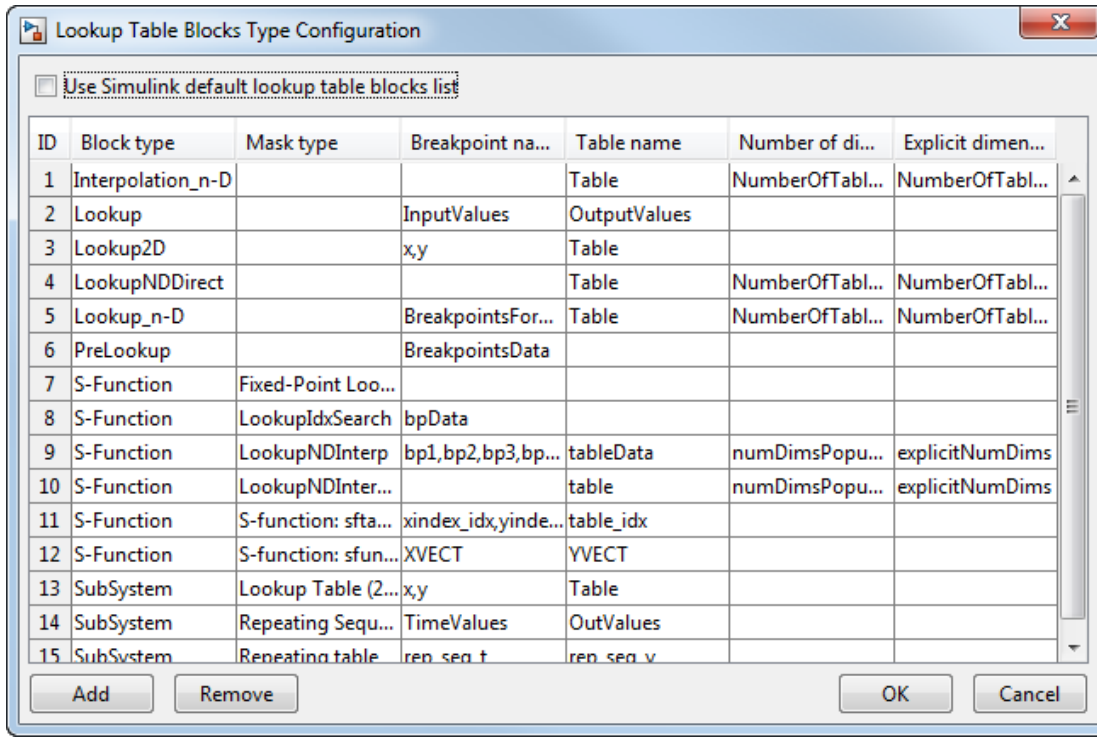
For example, the following selector displays slice (:,:,1) of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

1 Select **File** > **Configure**. The Lookup Table Blocks Type Configuration dialog box appears.



The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.

3 Enter information for the custom block in the new row under these headings.

Field Name	Description
Block type	Block type of the custom block. The block type is the value of the block's `BlockType` parameter.
Mask type	Mask type of the custom block. The mask type is the value of the block's `MaskType` parameter.
Breakpoint name	Names of the block parameters that store the breakpoints.
Table name	Name of the block parameter that stores the table data.
Number of dimensions	Leave empty.
Explicit dimensions	Leave empty.

4 Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

More About

Import Lookup Table Data from MATLAB

In this section...
“Import Standard Format Lookup Table Data” on page 35-30
“Propagate Standard Format Lookup Table Data” on page 35-31
“Import Nonstandard Format Lookup Table Data” on page 35-32
“Propagate Nonstandard Format Lookup Table Data” on page 35-33

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

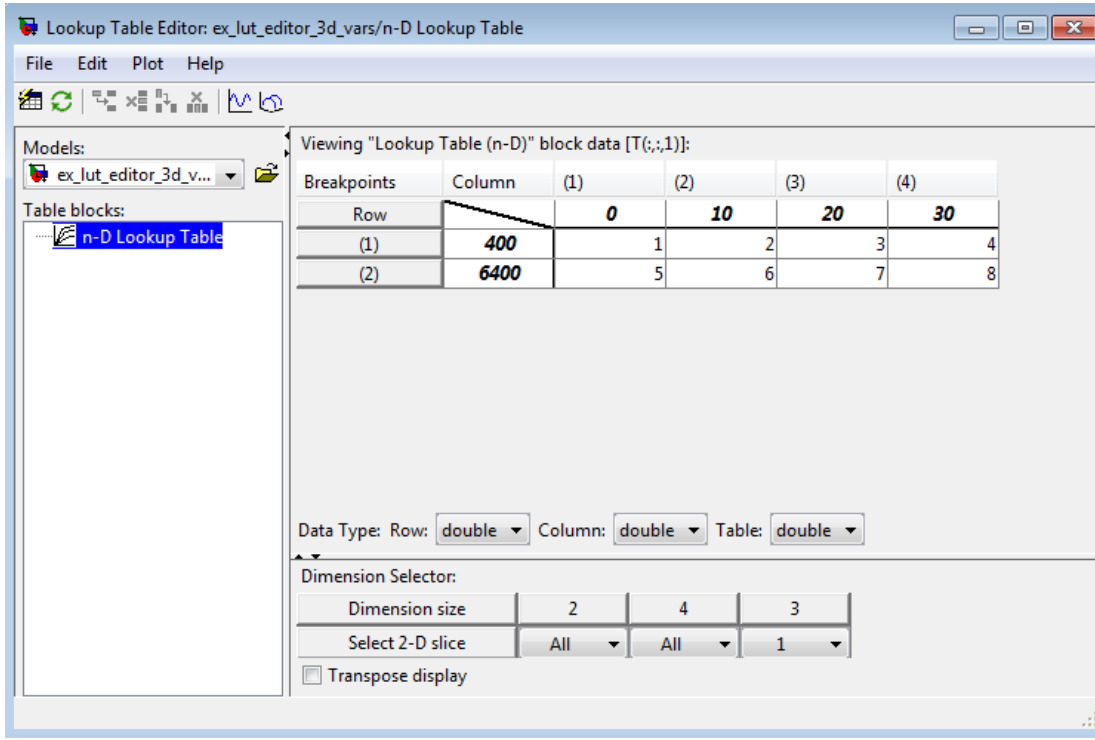
Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [     1     2     3     4;      5     6     7     8];
table3d_map(:,:,2) = [    11    12    13    14;     15    16    17    18];
table3d_map(:,:,3) = [   111   112   113   114;   115   116   117   118];
bp3d_z =[  0    10    20];
bp3d_x =[     0    10    20    30];
bp3d_y =[   400  6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d_map
- Breakpoints 1: bp3d_y
- Breakpoints 2: bp3d_x
- Breakpoints 3: bp3d_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.



Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File** > **Update Block Data**.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in "Import Standard Format Lookup Table Data" on page 35-30. For example, change the value of the data in (1,1,1) from `1` to `33`. To propagate this change back to `table3d_map` in the workspace, select **File** > **Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

Import Nonstandard Format Lookup Table Data

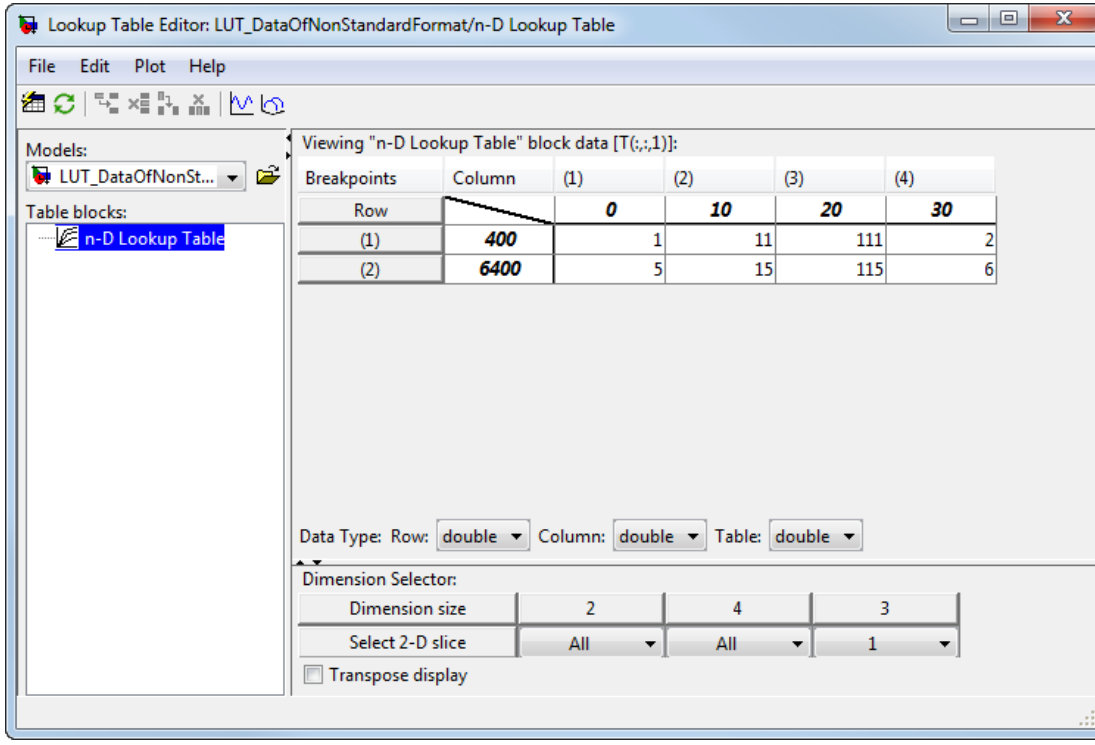
Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [     1     2     3     4;       5     6     7     8;
11      12     13      14;         15      16      17     18;
111   112    113    114;     115    116    117    118];
bp3d_z =[  0    10    20];
bp3d_x =[  0    10    20    30];
bp3d_y =[  400  6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the `reshape` command below.

- Table data: `reshape(table3d_map_custom,[2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.



Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 35-33.

Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 35-32 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable

`table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

1. Create a file named `sl_customization.m` with these contents.

```
function sl_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

   In this function:

   - The argument `cm` is the handle to a customization manager object.
   - The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

2. In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk,tableStr)
        blkInfo.allowTableConvertLocal = true;
        blkInfo.tableWorkSpaceVarName = 'table3d_map_custom';
        blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

   The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

   - `allowTableConvertLocal` — Allows table data conversion for a block.
   - `tableWorkSpaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
   - `tableConvertFcnHandle` — Specifies the handle for the conversion function.

   When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkSpaceVarName`. The conversion function corresponds to the handle that `tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

3. In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* * *Columns* * *Height* to a two-dimensional variable of size *(Rows*Height)* * *Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)

% Determine the row and column number of the 3D table data
    mapDim = size(data);
    numCol = mapDim(2);
    numRow = mapDim(1)*mapDim(3);
    cMap = zeros(numRow, numCol);
   % Transform data back to a 2-dimensional matrix
    cMap = reshape(data,[numRow,numCol]);
end
```

4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see "Behavior with Multiple Customization Functions" on page 35-36.

5 Refresh Simulink customizations at the MATLAB command prompt.

```
sl_refresh_customizations
```

6 Open the Lookup Table Editor for your lookup table block and select **File** > **Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.

7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

Note: If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

- "Import Lookup Table Data from Excel" on page 35-37

Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

1. Save the Excel file in a folder on the MATLAB path.
2. Open the model containing the lookup table block and select **File** > **Model Properties** > **Model Properties**.
3. In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
4. Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet','Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

5. Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

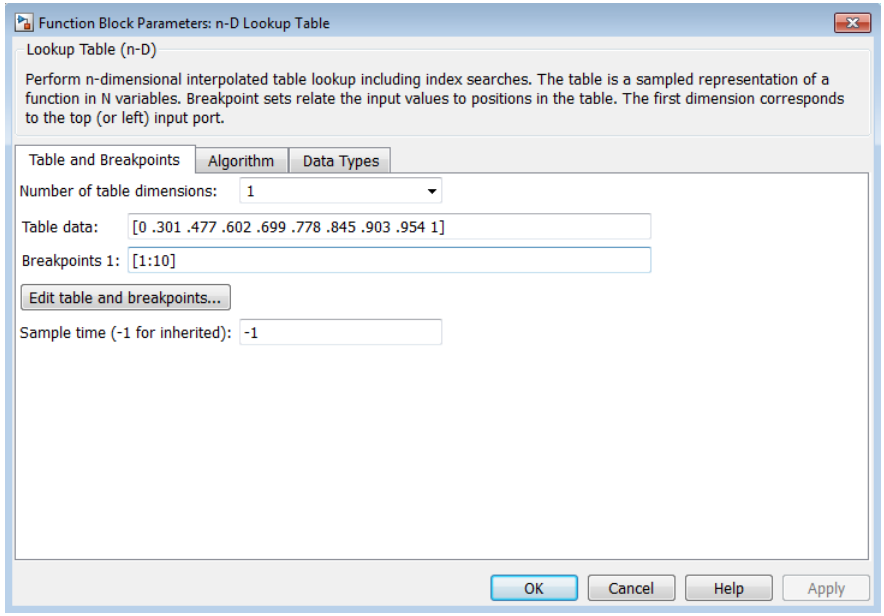
- "Import Lookup Table Data from MATLAB" on page 35-30

Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

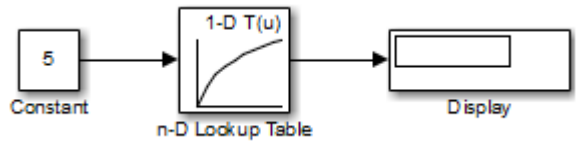
1. Copy the following blocks to a Simulink model:
   - One `Constant` block to input the signal, from the Sources library
   - One `n-D Lookup Table` block to approximate the common logarithm, from the Lookup Tables library
   - One `Display` block to display the output, from the Sinks library
2. Assign the table data and breakpoint data set to the `n-D Lookup Table` block:
   a. In the **Number of table dimensions** field, enter `1`.
   b. In the **Table data** field, enter `[0 .301 .477 .602 .699 .778 .845 .903 .954 1]`.
   c. In the **Breakpoints 1** field, enter `[1:10]`.
   d. Click **Apply**.

   The dialog box looks something like this:



3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to `5`. Click **OK** to apply the changes and close the dialog box.

4 Connect the blocks as follows.



5 Start simulation.

The following behavior applies to the `n-D Lookup Table` block.

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Equals a breakpoint	Returns the corresponding output value	5	0.699
Falls between breakpoints	Linearly interpolates the output value using neighboring breakpoints	7.5	0.874
Falls outside the range of the breakpoint data set	Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set	10.5	1.023

For the `n-D Lookup Table` block, the default settings for **Interpolation method** and **Extrapolation method** are both `Linear`.

Prelookup and Interpolation Blocks

The following examples show the benefits of using `Prelookup` and `Interpolation Using Prelookup` blocks.

Action	Benefit	Example
Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs	Enables reuse of index search results to look up data in multiple tables, which reduces simulation time	To open the model, type `sldemo_bpcheck` at the command prompt.
Set breakpoint and table data types explicitly	Lowers memory required to store: • Breakpoint data that uses a smaller type than the input signal • Table data that uses a smaller type than the output signal	To open the model, type `sldemo_interp_memory` at the command prompt.
	Provides easier sharing of: • Breakpoint data among `Prelookup` blocks • Table data among `Interpolation Using Prelookup` blocks	To open the model, type `fxpdemo_lookup_shared_param` at the command prompt.
	Enables reuse of utility functions in the generated code	To open the model, type `fxpdemo_prelookup_utilfcn` at the command prompt.
Set the data type for intermediate results explicitly	Enables use of higher precision for internal computations than for table data or output data	To open the model, type `fxpdemo_interp_precision` at the command prompt.

Optimize Generated Code for Lookup Table Blocks

In this section...
"Remove Code That Checks for Out-of-Range Inputs" on page 35-43
"Optimize Breakpoint Spacing in Lookup Tables" on page 35-45

Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- `1-D Lookup Table`
- `2-D Lookup Table`
- `n-D Lookup Table`
- `Prelookup`
- `Interpolation Using Prelookup`

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

Block	Check Box to Select
`1-D Lookup Table`	**Remove protection against out-of-range input in generated code**
`2-D Lookup Table`	
`n-D Lookup Table`	
`Prelookup`	
`Interpolation Using Prelookup`	**Remove protection against out-of-range index in generated code**

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

Model Advisor Check	When to Run the Check
By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code	For code efficiency
By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks	For safety-critical applications

For more information about the Model Advisor, see “Consulting the Model Advisor” on page 5-2 in the Simulink documentation.

Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Execution speed	The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation.	The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.	The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations.
Error	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.
ROM usage	Uses less command ROM, but more data ROM.	Uses less command ROM, but more data ROM.	Uses more command ROM, but less data ROM.
RAM usage	Not significant.	Not significant.	Not significant.

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see "Consulting the Model Advisor" on page 5-2 in the Simulink documentation.

Update Lookup Table Blocks to New Versions

In this section...
"Comparison of Blocks with Current Versions" on page 35-47
"Compatibility of Models with Older Versions of Lookup Table Blocks" on page 35-48
"How to Update Your Model" on page 35-49
"What to Expect from the Model Advisor Check" on page 35-49

Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

Block	Changes	Enhancements

Lookup Table	• Block renamed as `1-D Lookup Table`
	• Icon changed
		• Default integer rounding mode changed from `Floor` to `Simplest`
		• Support for the following features:
		  • Specification of parameter data types different from input or output signal types
		  • Reduced memory use and faster code execution for nontunable breakpoints with even spacing
		  • Cubic-spline interpolation and extrapolation
		  • Table data with complex values
		  • Fixed-point data types with word lengths up to 128 bits
		  • Specification of data types for fraction and intermediate results
		  • Specification of index search method
		  • Specification of diagnostic for out-of-range inputs

Lookup Table (2-D)	• Block renamed as `2-D Lookup Table` • Icon changed	• Default integer rounding mode changed from `Floor` to `Simplest` • Support for the following features:

Block	Changes	Enhancements
		• Specification of parameter data types different from input or output signal types • Reduced memory use and faster code execution for nontunable breakpoints with even spacing • Cubic-spline interpolation and extrapolation • Table data with complex values • Fixed-point data types with word lengths up to 128 bits • Specification of data types for fraction and intermediate results • Specification of index search method • Specification of diagnostic for out-of-range inputs • Check box for **Require all inputs to have the same data type** now selected by default
Lookup Table (n-D)	• Block renamed as `n-D Lookup Table` • Icon changed	• Default integer rounding mode changed from `Floor` to `Simplest`

Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

Block	Old Block Path	New Block Path
Lookup Table	`simulink/Lookup Tables/Lookup Table`	`simulink/Lookup Tables/1-D Lookup Table`

Block	Old Block Path	New Block Path
Lookup Table (2-D)	`simulink/Lookup Tables/Lookup Table (2-D)`	`simulink/Lookup Tables/2-D Lookup Table`
Lookup Table (n-D)	`simulink/Lookup Tables/Lookup Table (n-D)`	`simulink/Lookup Tables/n-D Lookup Table`

How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

Step	Action	Reason
1	Run the Upgrade Advisor.	Identify blocks that do not have compatible settings with the `1-D Lookup Table` and `2-D Lookup Table` blocks.
2	For each block that does not have compatible settings: • Decide how to address each warning. • Adjust block parameters as needed.	Modify each `Lookup Table` or `Lookup Table (2-D)` block to ensure compatibility with the current versions.
3	Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.	Ensure that block replacement works for the entire model.

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the `1-D Lookup Table` and `2-D Lookup Table` blocks. For more information about the Upgrade Advisor, see "Model Upgrades".

What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the `1-D Lookup Table` and `2-D Lookup Table` blocks
- Blocks that have incompatible settings with the `1-D Lookup Table` and `2-D Lookup Table` blocks

- Blocks that have repeated breakpoints

Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

Lookup Method in the Lookup Table or Lookup Table (2-D) Block	Parameter Settings After Automatic Block Replacement	
	Interpolation	Extrapolation
`Interpolation-Extrapolation`	`Linear`	`Linear`
`Interpolation-Use End Values`	`Linear`	`Clip`
`Use Input Below`	`Flat`	Not applicable

Depending on breakpoint spacing, one of two index search methods can apply.

Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block	Index Search Method After Automatic Block Replacement
Not evenly spaced	`Binary search`
Evenly spaced and tunable	A prompt appears, asking you to select `Binary search` or `Evenly spaced points`.
Evenly spaced and not tunable	

Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
The **Lookup Method** is `Use Input Nearest` or `Use Input`	Change the lookup method to one of the following options:	The **Lookup Method** changes to `Interpolation - Use End Values`.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
`Above`. The replacement block does not support these lookup methods.	• `Interpolation - Extrapolation` • `Interpolation - Use End Values` • `Use Input Below`	In the replacement block, this setting corresponds to: • **Interpolation** set to `Linear` • **Extrapolation** set to `Clip` You also see a message that explains possible numerical differences.
The **Lookup Method** is `Interpolation - Extrapolation`, but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.	Change the extrapolation method or the port data types of the block.	
The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.	None	You see a message that explains possible numerical differences.

Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

Lookup Table Glossary

The following table summarizes the terminology used to describe lookup tables in the Simulink user interface and documentation.

Term	Meaning
breakpoint	A single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped.
breakpoint data set	A vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.
extrapolation	A process for estimating values that lie beyond the range of known data points.
interpolation	A process for estimating values that lie between known data points.
lookup table	An array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a “lookup” operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding.
monotonically increasing	The elements of a set are ordered such that each successive element is greater than or equal to its preceding element.
rounding	A process for approximating a value by altering its digits according to a known rule.
strictly monotonically increasing	The elements of a set are ordered such that each successive element is greater than its preceding element.

Term	Meaning
table data	An array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value.

Masking Fundamentals

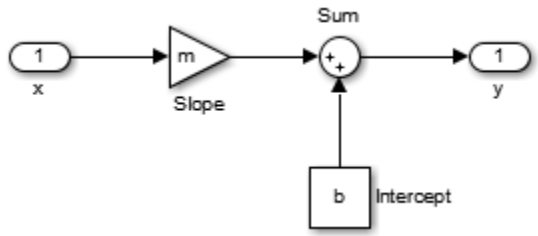
Mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and is saved along with it. A mask changes only the interface to the block, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

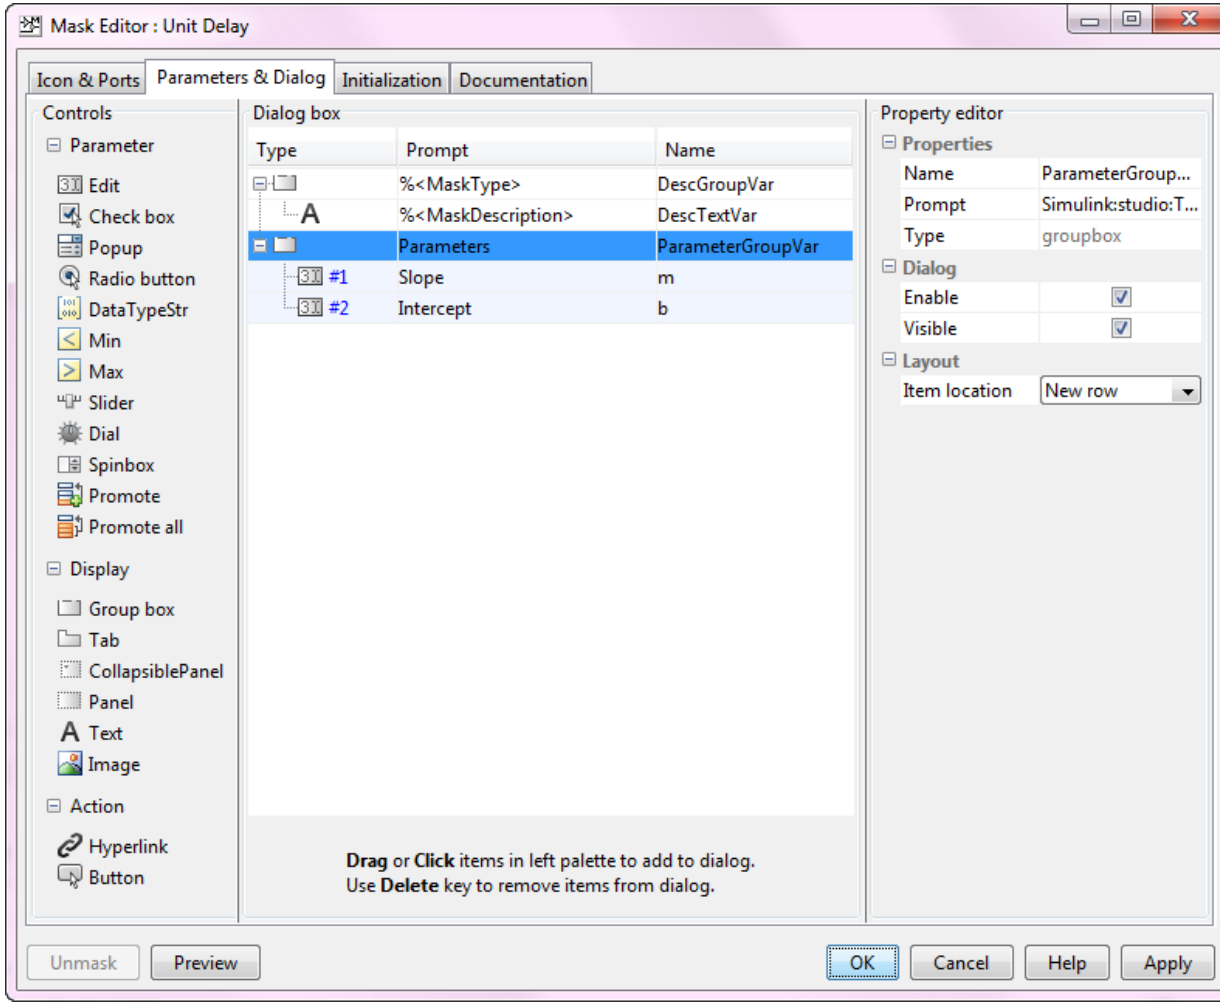
You can mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model masking_example that governs the equation of line `y = mx + b`.

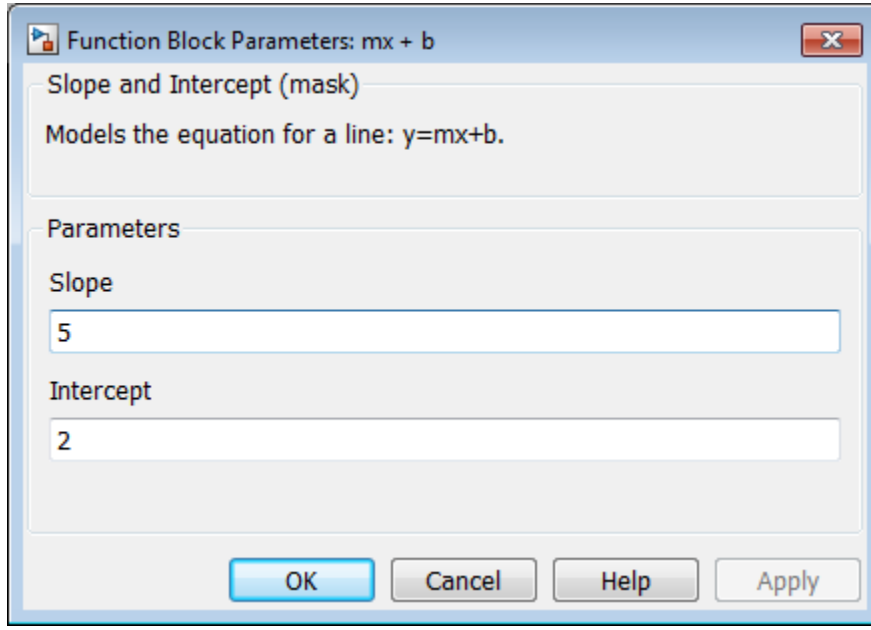


Each block has its own block dialog box making it complicated to specify the values for the variables for the line equation. To simplify the user interface, a mask is applied on the top-level subsystem block.



Here the variable `m` represents slope and the variable `b` represents the intercept for the line equation `y = mx + b`.

The mask dialog box displays the fields for Slope and Intercept that are internally mapped to variables `m` and `b`.



If you use a mask only to represent the contents of a subsystem, consider using content preview instead. Masked blocks do not support content preview. For details, see “Preview Content of Hierarchical Items” on page 1-51 .

Tip To view the masking examples, see Simulink Masking Examples. Notice that the examples of similar type are grouped. In an example model,

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Masking Terminology

Terminology Table

Term	Description
Mask icon	The masked block icon generated using drawing commands. Mask icon can be static or change dynamically with underlying block parameter values.
Mask parameters	The parameters that are defined in Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.
Mask initialization code	MATLAB code that initializes a masked block or reflects current parameter values. Add mask initialization code in the **Initialization** pane of Mask Editor dialog box. For examples, add initialization code to set a parameter value automatically.
Mask dialog callback code	MATLAB code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically to reflect current parameter values. For example, enable visible parameters on the dialog box.
Mask documentation	Description and usage information for a masked block defined in the Mask Editor.
Mask dialog box	A dialog box that contains fields for setting mask parameter values and provides mask description.
Mask workspace	Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.

More About

- “Block Masks”
- “Create a Simple Mask” on page 36-6
- “Mask Editor Overview”
- Set mask parameters
- Group parameters under tabs

Create a Simple Mask

You can mask a block interactively by using the **Mask Editor** or mask it programmatically. This example describes how to mask a block with the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 36-36.

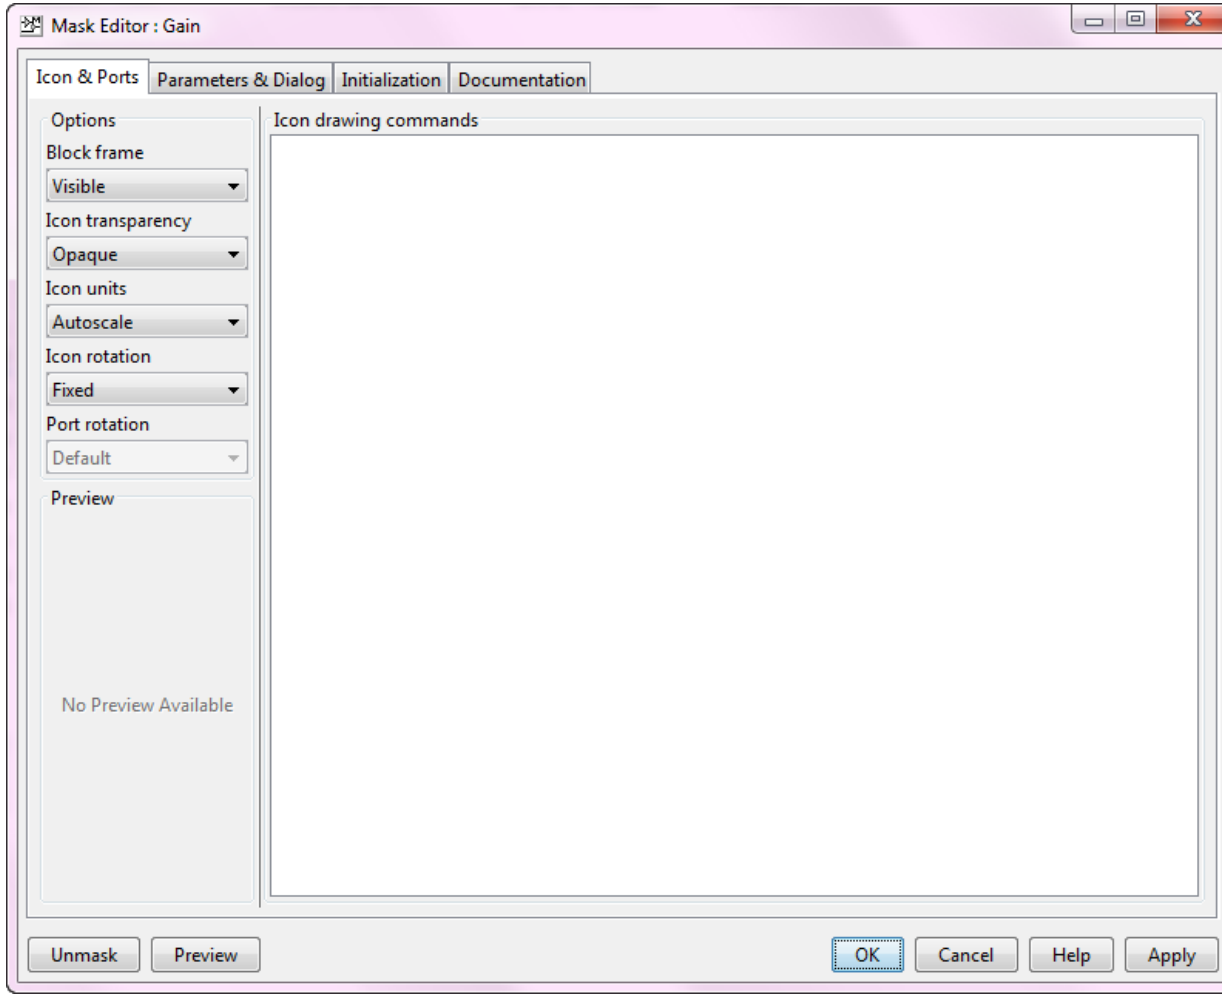
To view masking examples, see Simulink Masking Examples.

Step 1: Open Mask Editor

1. Open the model in which you want to mask a block. For example, open `subsystem_example`.

   This model contains a Subsystem block that models the equation for a line: `y = mx + b`.

2. Right-click the Subsystem block and select **Mask** > **Create Mask**.



Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

For detailed information on each pane, see “Mask Editor Overview”.

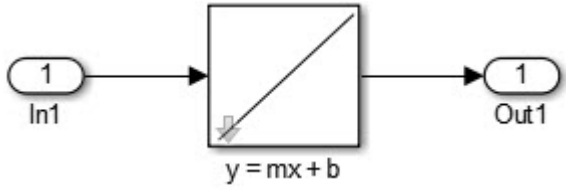
Icon & Ports Tab

Use this tab to create an icon for the block mask. You can use the **Options** pane on the left to specify icon properties and icon visibility.

Add an image to the block mask.

1. In the **Block frame** drop-down box, select **Visible**.
2. In the **Icon transparency** drop-down box, select **Opaque**.
3. In the **Icon units** drop-down box, select **Autoscale**.
4. In the **Icon rotation** drop-down box, select **Fixed** to restrict the icon rotation.
5. In the **Icon drawing commands** text box, type `plot(y,x)`.

   For more information on drawing command syntax, see "Icon drawing commands".
6. To save the changes, click **Apply**.
7. To preview the block mask icon without exiting the **Mask Editor**, click **Preview**.



Note: For detailed information, see "Icon & Ports Pane".

You can create static or dynamic block mask icons. For more information, see "Draw Mask Icon" on page 36-20 and slexMaskDisplayAndInitializationExample.

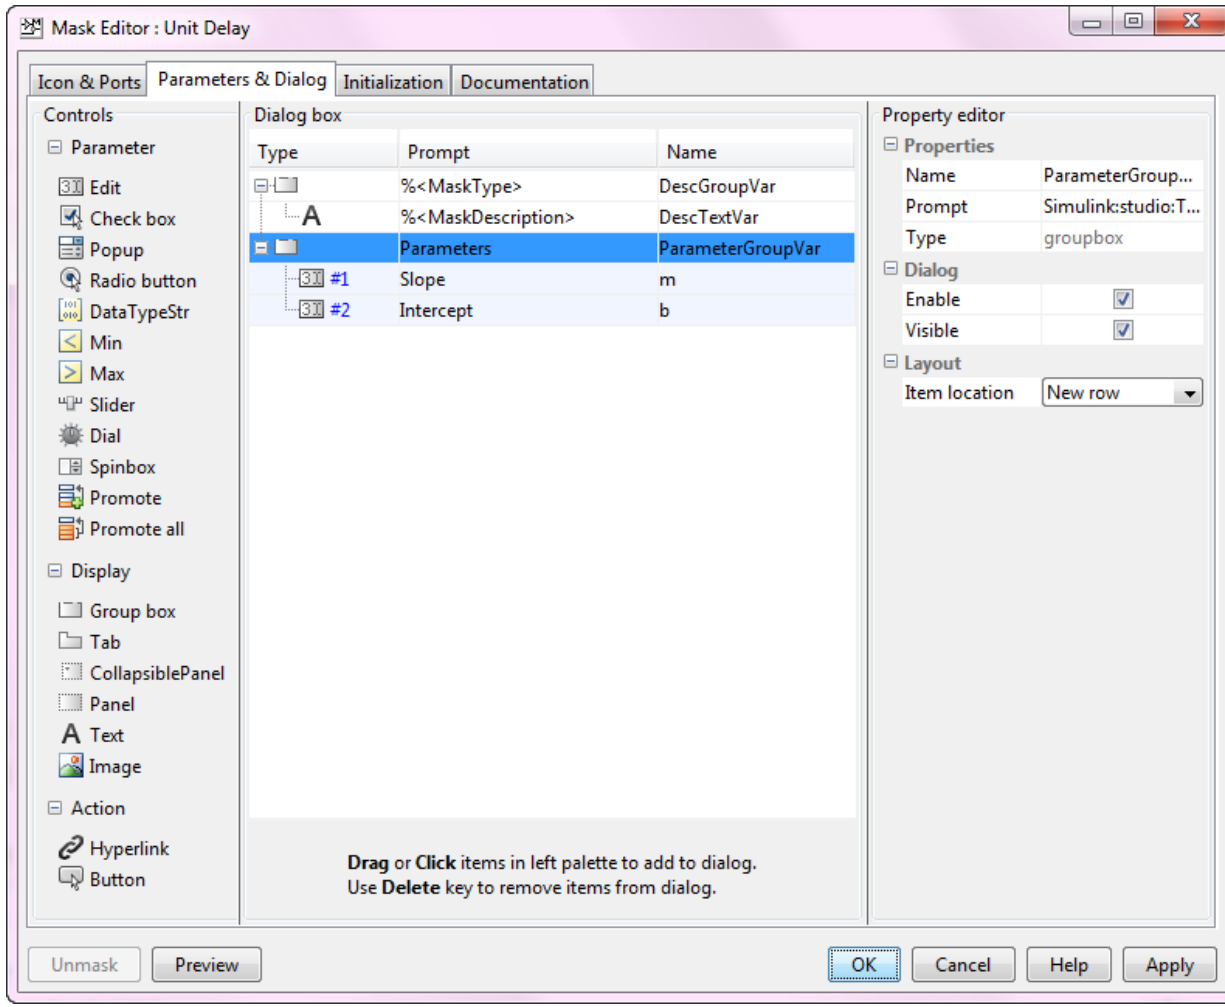
Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

Add **Edit** boxes to the block mask.

1. In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.

2. Type `Slope` and `Intercept` in the **Prompt** and **Name** columns, respectively. The value that you enter in **Prompt** column appears on the mask dialog box. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
3. In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
4. Click **Apply**.



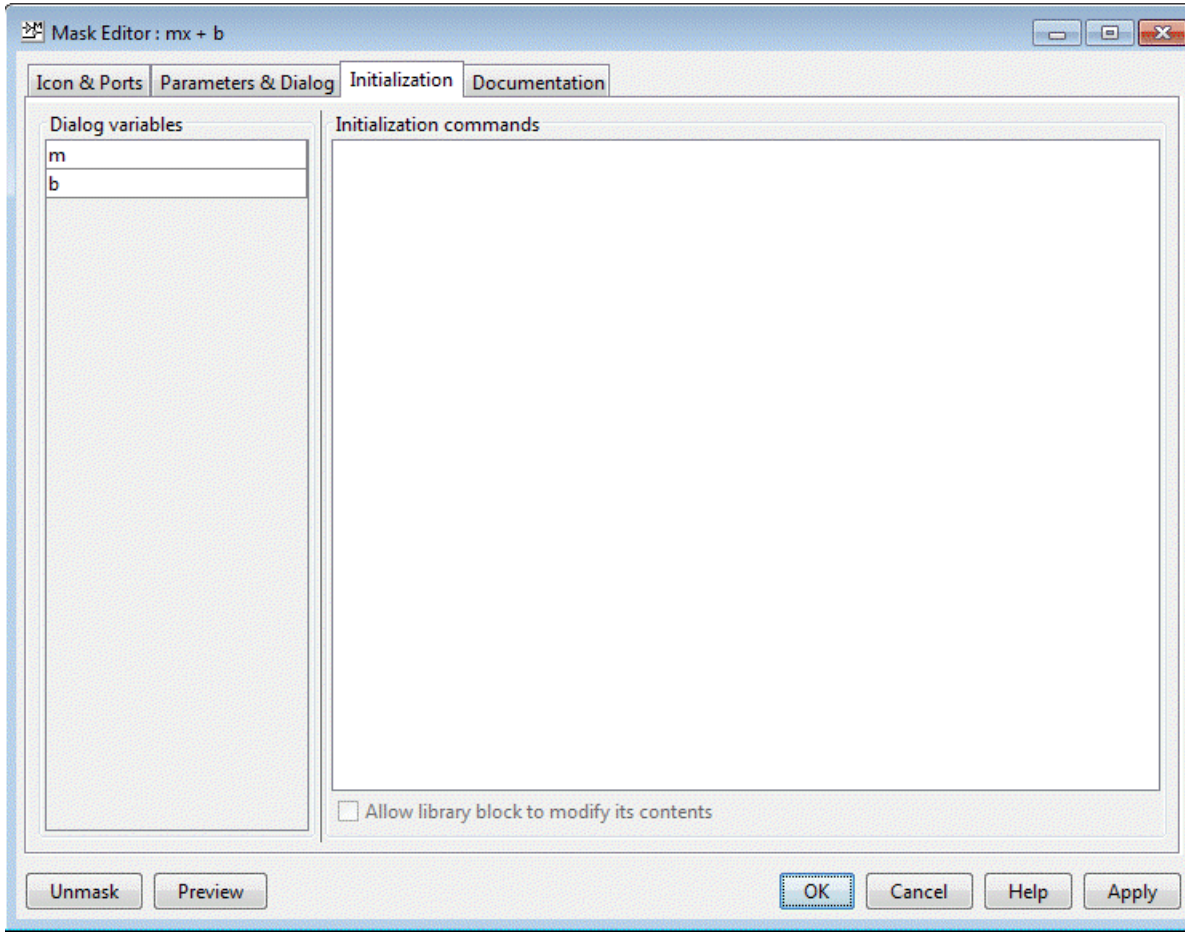
5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

Note: For detailed information, see "Parameters & Dialog Pane".

Initialization Tab

Use this pane to specify MATLAB code to control the mask parameters. You can add conditions for the user specified values, provide a predefined value for a mask parameter, and so on.

For example, consider the equation `y = mx + b`. To allow positive value for `m`, you can add MATLAB code in initialization pane to specify the acceptable range for `m` as greater than zero.



Note: For detailed information, see “Initialization Pane”.

Documentation Tab

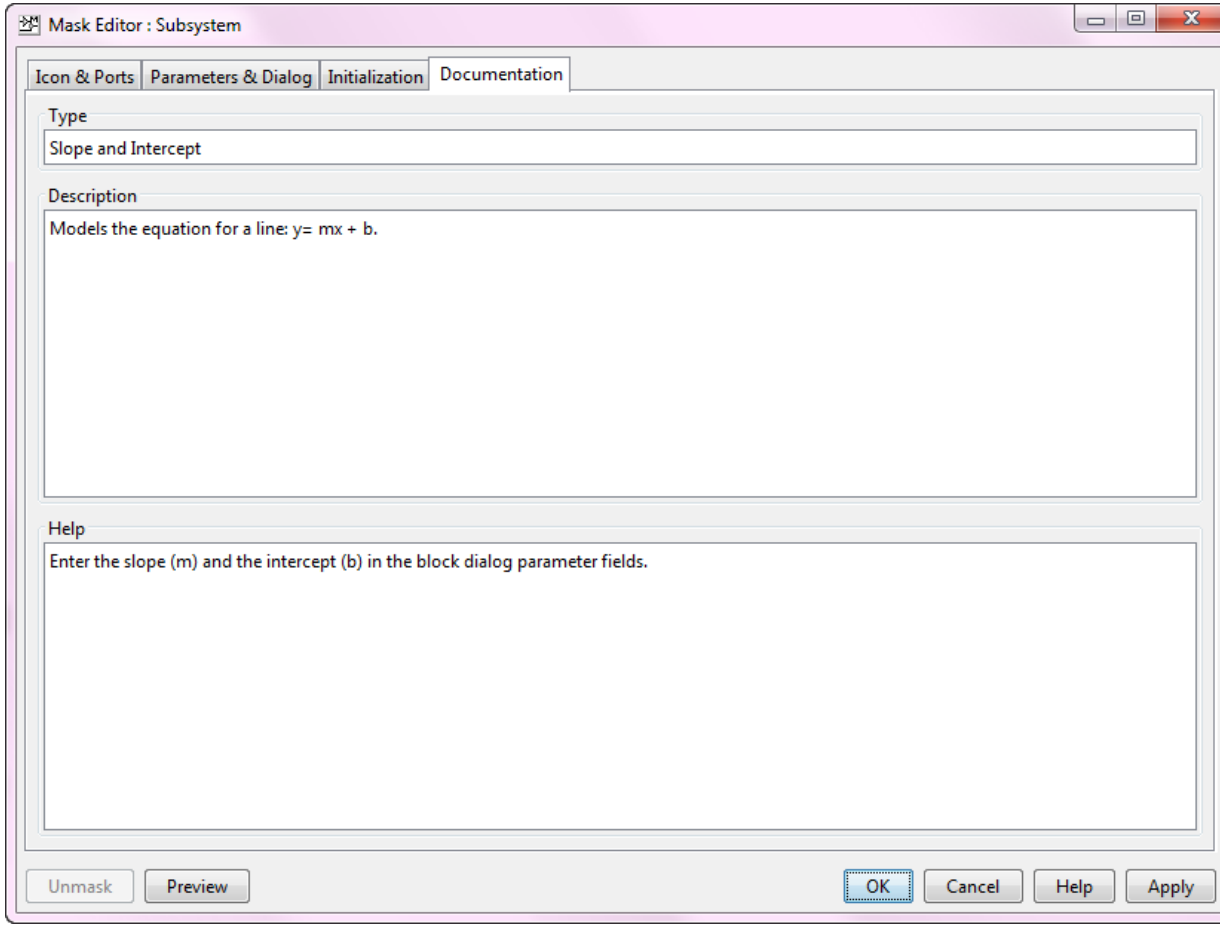
Use this tab to add a name, description, and additional information for the mask.

The **Documentation** tab contains these fields:

1. **Type**: You can add a name for the block mask in this box. The mask name appears on top of the mask dialog box. You cannot add new lines.
2. **Description**: You can add a description for the block mask in this box. By default, the description is displayed below the mask name, and it can contain new lines and spaces.
3. **Help**. You can add additional information for the block mask in this box. You click **Help** on the mask dialog box, this information is displayed. You can use plain text, HTML and graphics, URLs, and web or eval commands to add information in the **Help** field.

   After you have added information in the **Mask Editor**, click **Apply** or **OK**.

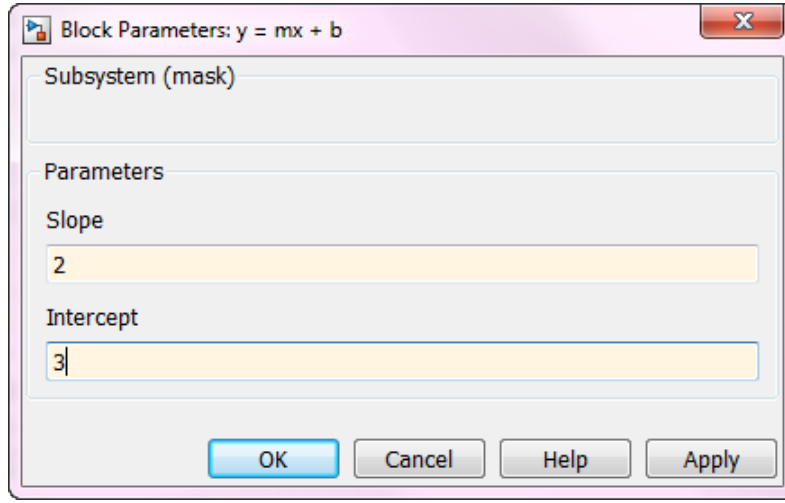
   The block is now masked.



Note: For detailed information, see “Documentation Pane”.

Step 3: Operate on Mask

1. You can preview the mask and choose to unmask the block or edit the block mask.
2. Double-click the masked block.



The mask dialog box appears.

3 Type values in the `Slope` and `Intercept` boxes of the mask dialog box. To view the output, simulate the model.

4 Click **OK**.

5 To edit the mask definition, right-click the block and select **Mask > Edit Mask**. For more information, see "Operate on Existing Masks" on page 36-15.

6 Right-click the masked block and select **Mask > Look Under Mask** to view:

- The blocks inside the masked subsystem
- The built-in block dialog box of a masked block
- The base mask dialog box of a linked masked block

See Also

"Block Masks" | "Mask Editor Overview" | "Masking Fundamentals" on page 36-2

Operate on Existing Masks

Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

1. Select the masked block.
2. Select **Mask > Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, be sure to save the model before closing it, or the changes will be lost.

View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, right-click the block and select **Mask > Mask Parameters** or click **Diagram > Mask > Mask Parameters**.

Tip Each block has a block parameter dialog box its own block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

Look Under Block Mask

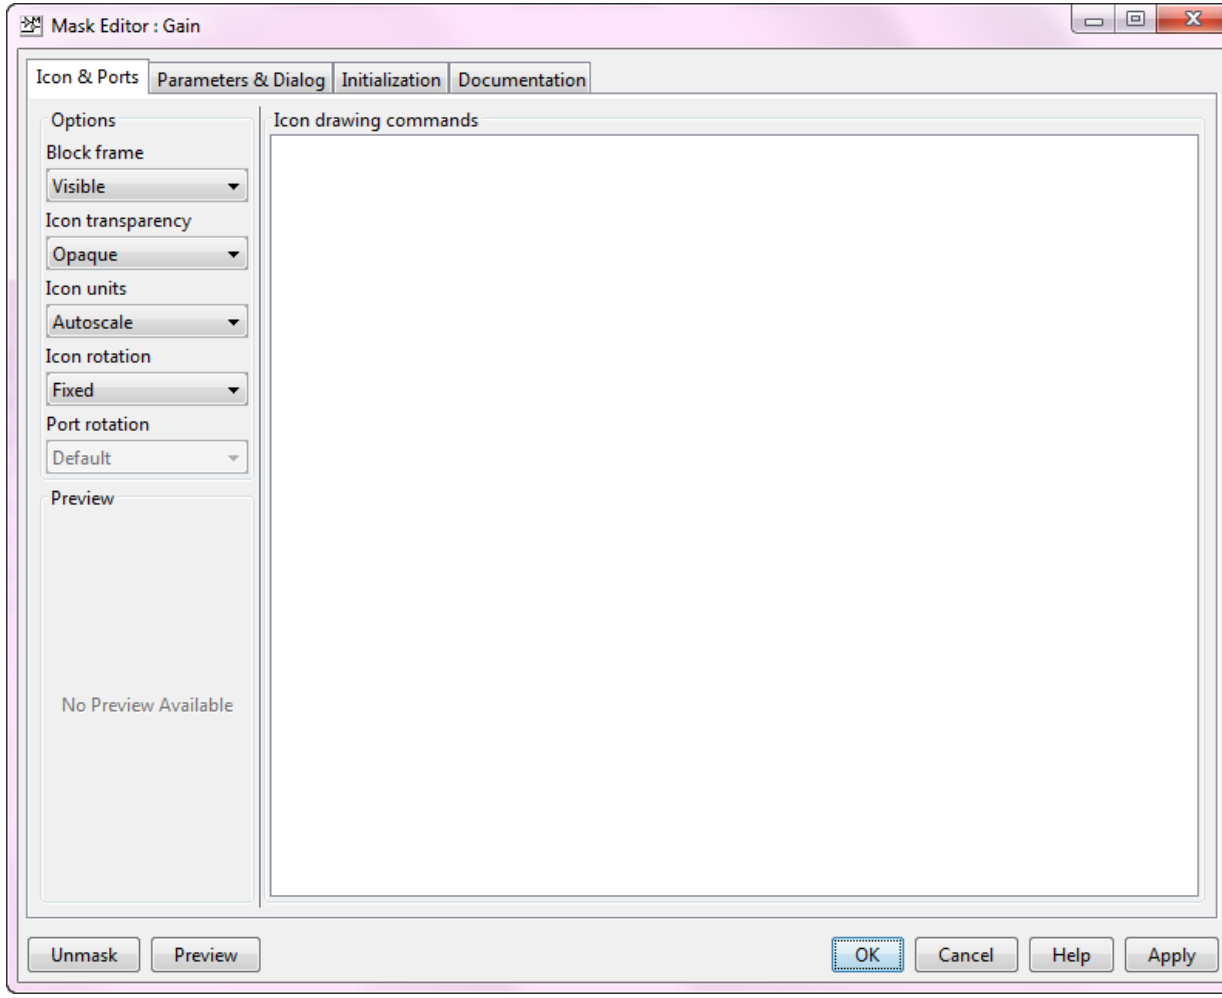
To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, right-click the block and select **Mask > Look Under Mask**.

Remove Mask

To remove a mask from a block and delete:

1. Right-click the block.
2. Select **Mask > Edit Mask**.

   The Mask Editor opens and displays the existing mask, for example:



3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block.

Mask Code Execution

In this section...
“Adding Mask Code” on page 36-17
“Drawing Command Execution” on page 36-17
“Initialization Command Execution” on page 36-18
“Callback Code Execution” on page 36-18

Adding Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

Purpose	Add in Mask Editor	Programmatic Specification
Initialize the mask	**Initialization** pane	`MaskInitialization` parameter
Draw mask icon	**Icon & Ports** pane	`MaskDisplay` parameter
Callback code for mask parameters	**Parameters & Dialog** pane	`MaskCallbacks` parameter

Drawing Command Execution

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon in the following cases:

- Block is rendered first on the Mask Editor canvas
- Drawing commands depend mask parameters and the values of these mask parameters change
- Block appearance is altered due to rotation or other changes.

Note: Model performance is affected if you place MATLAB code for drawing mask icons in the **Initialization** pane. This is because Simulink redraws the icon each time the masked block is evaluated in the model.

Initialization Command Execution

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as `MaskDisplay` and `MaskInitialization`, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.
- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

  Note: Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-14 and `load_system` for information about loading a model without displaying it.

Callback Code Execution

Simulink executes the callback commands in the following cases:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor's focus (that is, you press the **Tab** key or click into another field in the dialog box).

  Note: When you modify the parameter value by using the `set_param` command, the callback commands do not execute.
- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands (See "Initialization Pane").
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

  Note: Callback commands do not execute if the mask dialog box is open when the block tool tip appears.
- Update a diagram (for example, by pressing **Ctrl+D** or by selecting **Simulation** > **Update diagram** in the Simulink Editor).
- If you close a mask dialog box without saving the changes, the Callback command for parameters is sequentially executed.

Note: Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

To view related examples, see

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

See Also

"Block Masks" | "Initialize Mask" on page 36-25

Draw Mask Icon

This example shows how to use drawing commands to create a mask icon. You can create icons that update when you change the mask parameters, thus reflecting the purpose of the block.

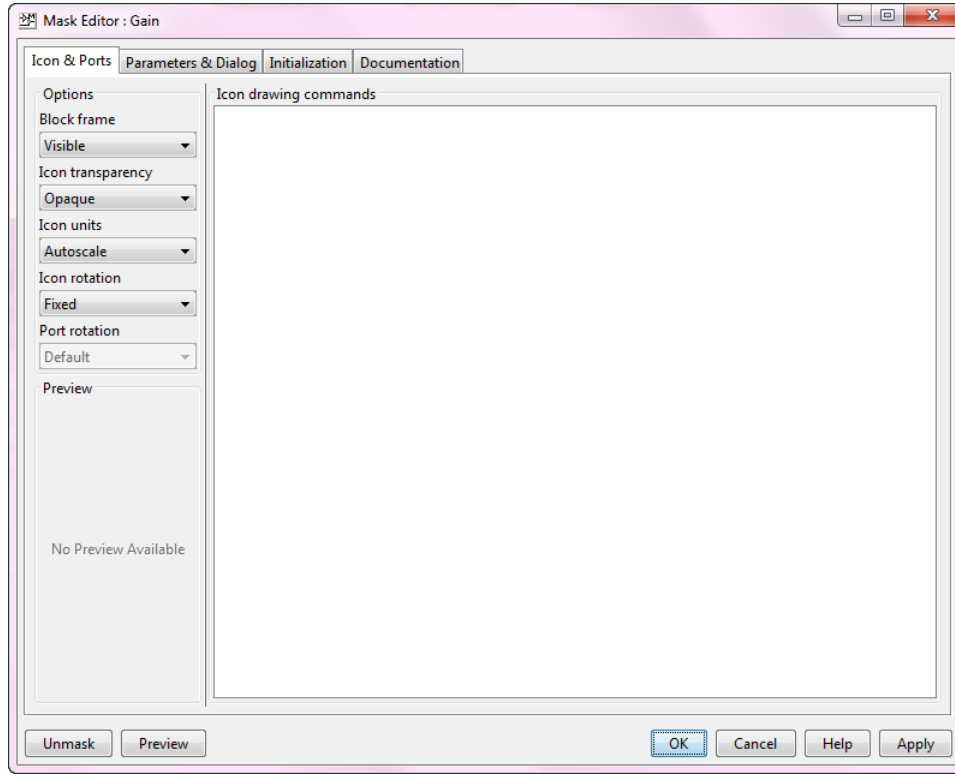
In this section...
“Draw Static Icon” on page 36-20
“Draw Dynamic Icon” on page 36-22
“Additional Examples” on page 36-24

Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.



2 In the **Icons & Ports** tab, enter the following command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

It is recommended that the image file must be on the MATLAB path. You can use images in `.svg` format as block mask image.

For more examples of drawing command syntax, explore the **Command** drop-down list in the **Examples of drawing commands** pane.

Images in formats: `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd` cannot be used as block mask images. However, you can use images in these formats if you wrap the file

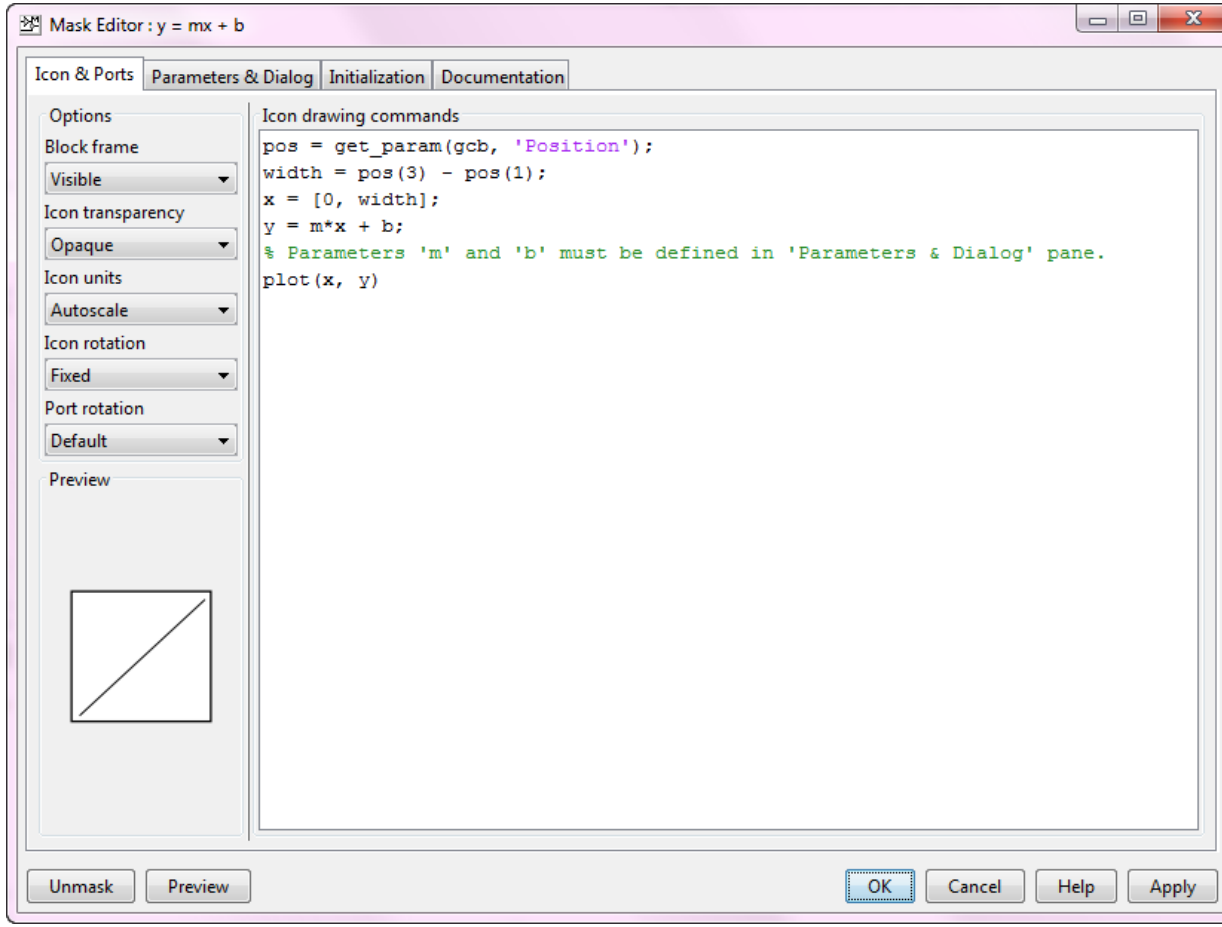
name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient, however it is still supported for backward compatibility.

Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

1 Right-click the masked block that requires the icon and select **Mask** > **Edit Mask**.

The Mask Editor opens.



2 In the **Icons & Ports** tab, enter the following command in the **Icon Drawing commands** pane:

```
pos = get_param(gcb, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)
```

3 Under **Options**, set **Icon Units** to `Pixels`.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

4 Click **Apply**. If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (`? ? ?`) appear on the mask. See model `masking_example` to view the icon generated.

Additional Examples

See model `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- a static mask
- a dynamic shape mask
- a dynamic text mask
- an image mask

"Block Masks"

Initialize Mask

You can add MATLAB code in the initialization pane of Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run (See "Initialization Command Execution" on page 36-18).

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter `a`, type `a = 5` in the initialization pane.
- To specify an acceptable range of inputs for mask parameter. For example, to specify the range between `0` and `10` as the acceptable values for parameter `a`, type `0 = a >= 10`.
- To specify value of a child block. For example,

  ```
  set_param('Child block Name','Parameter name','Parameter Value')
  ```

- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

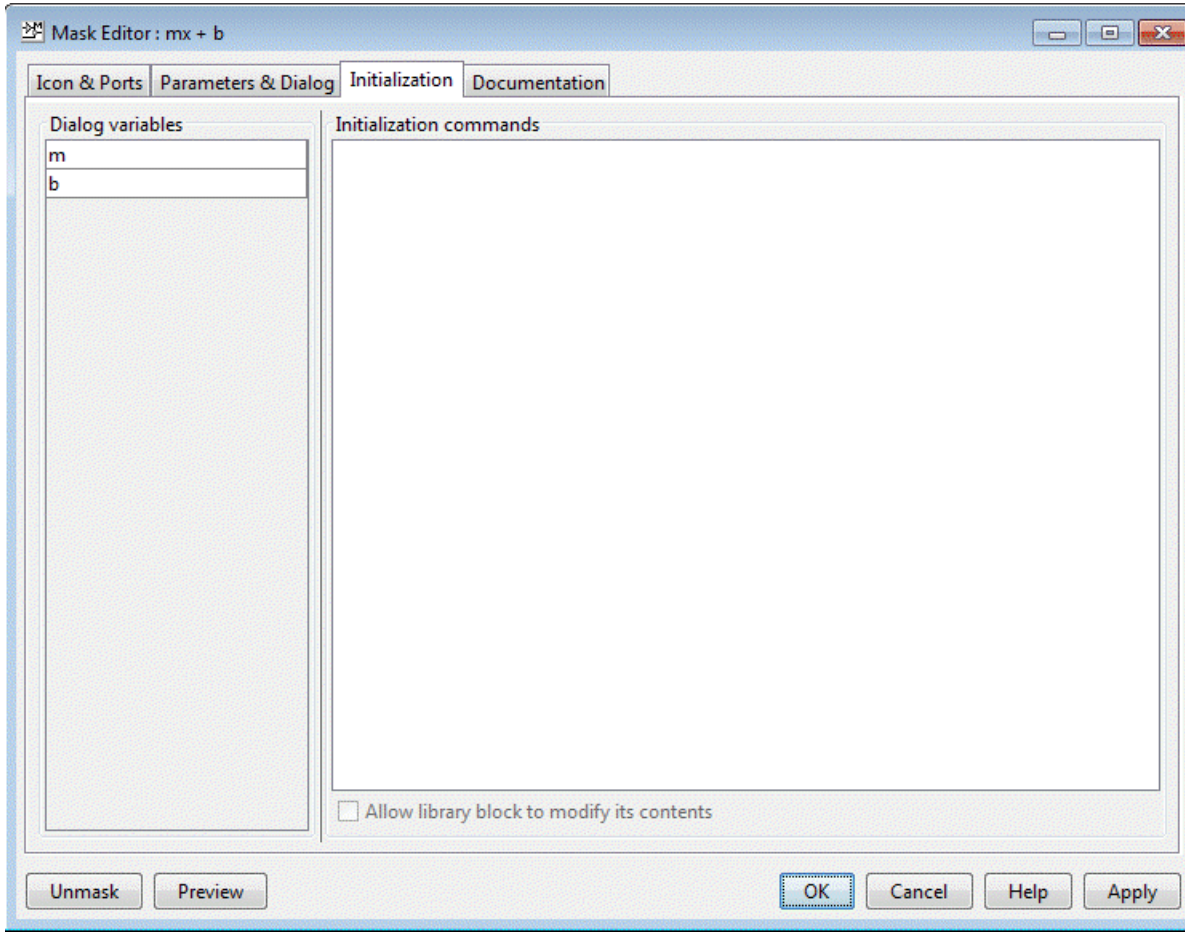
Note: Blocks that contain initialization code do not work as expected when using model reference.

Mask Editor Initialization Pane

Use the Mask Editor **Initialization** pane to add MATLAB commands that initialize a masked block.

The **Initialization** pane contains these sections:

- **Dialog variables**
- **Initialization commands**



Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization commands** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

Initialization Commands

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

Terminate initialization commands with a semicolon to avoid echoing results to the MATLAB Command Window.

To view related examples, see

- Define mask display and initialization
- Use handle graphics in masking

Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (that is, dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are specifically for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 36-52.
- Do not use `set_param` commands on blocks residing in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems. Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains the following command:

  ```
  set_param([gcb '/B/C'], 'SampleTime', '-1');
  ```

  Simulating or updating a model containing A causes an unresolved symbol error.
- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
  - `Simulink.Parameter` and subclasses
  - `Simulink.Signal` and subclasses
- Do not add initialization code to delete the same masked block.

- Use mask initialization code to control direct child blocks only.

Promote Parameter to Mask

In this section...
“Promote Underlying Parameters to Block Mask” on page 36-31
“Promote Underlying Parameters to Subsystem Mask” on page 36-33
“Best Practices” on page 36-35

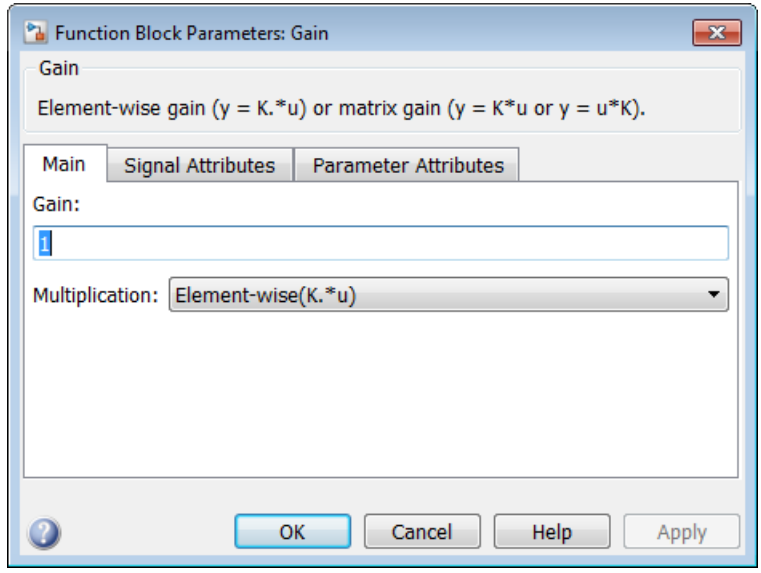
Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

Promote button on the Mask Editor enables you to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, allowing you to edit the parameter value from the mask dialog box.

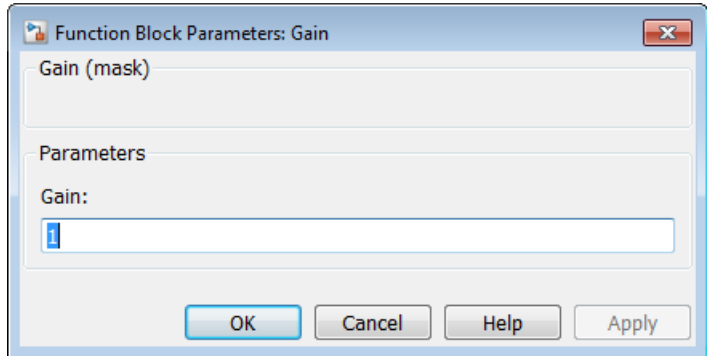
Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- In the case of library blocks, you can reuse a block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.



To expose only the Gain parameter, mask the Gain block and promote the Gain parameter to the mask dialog box.



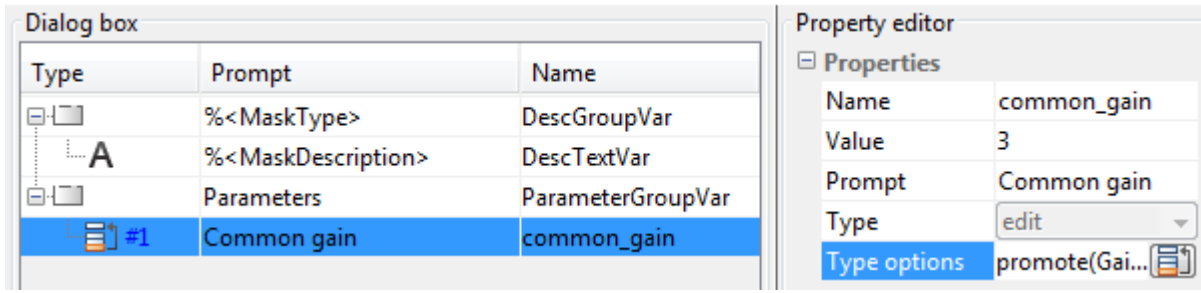
Similarly, you can mask a subsystem block and promote parameters to the mask from child blocks of the subsystem block. If the data type of subsystem child block parameters is same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

If the parameter is of data type `popup` or, `DataType` then the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

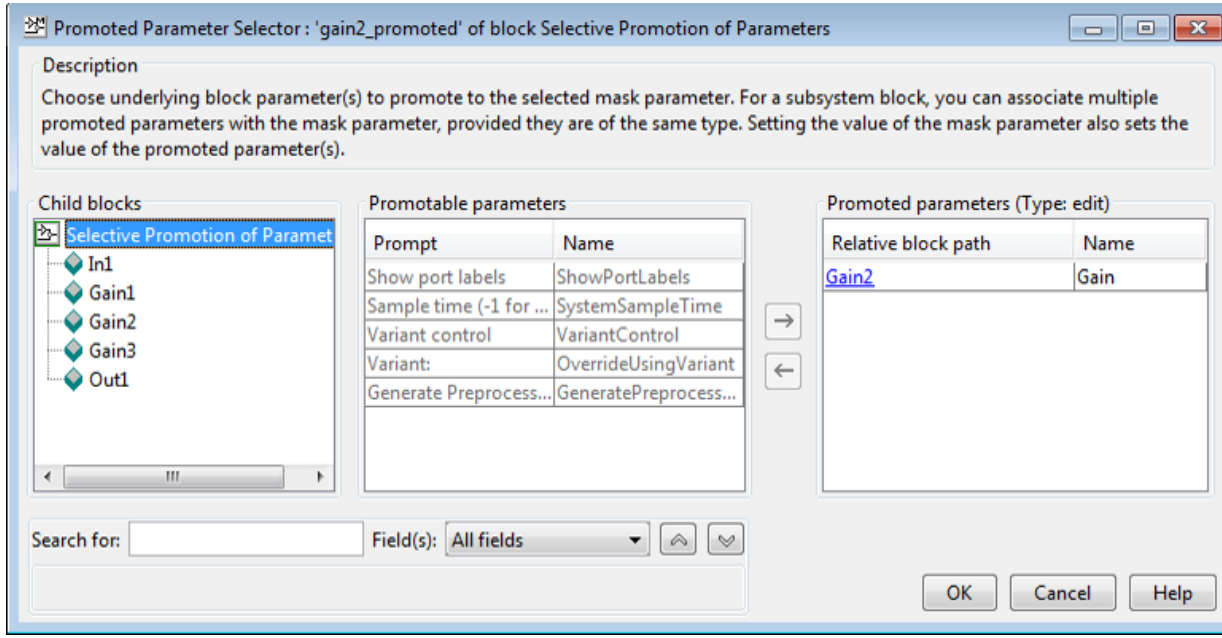
To view related example, see Promote mask parameters.

Promote Underlying Parameters to Block Mask

1. Right-click the block whose parameter you want to promote and select **Mask** > **Create Mask**.
2. In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
3. In the **Controls** pane, click **Promote**.
4. In the **Property editor** pane, next to **Type options**, click .



Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.



5 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

Tip

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
- To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.

6 Click **OK**.

7 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.

8 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Note:

- You can use **Promote all** to promote all parameters. **Promote all** is available for all block masks except for subsystem masks.
- To remove a promoted parameter, select the parameter and press **Delete** key.
- You cannot view or promote parameters of a nested masked or linked child block.

Promote Underlying Parameters to Subsystem Mask

1 Right-click the subsystem and select **Mask > Create Mask**.

2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.

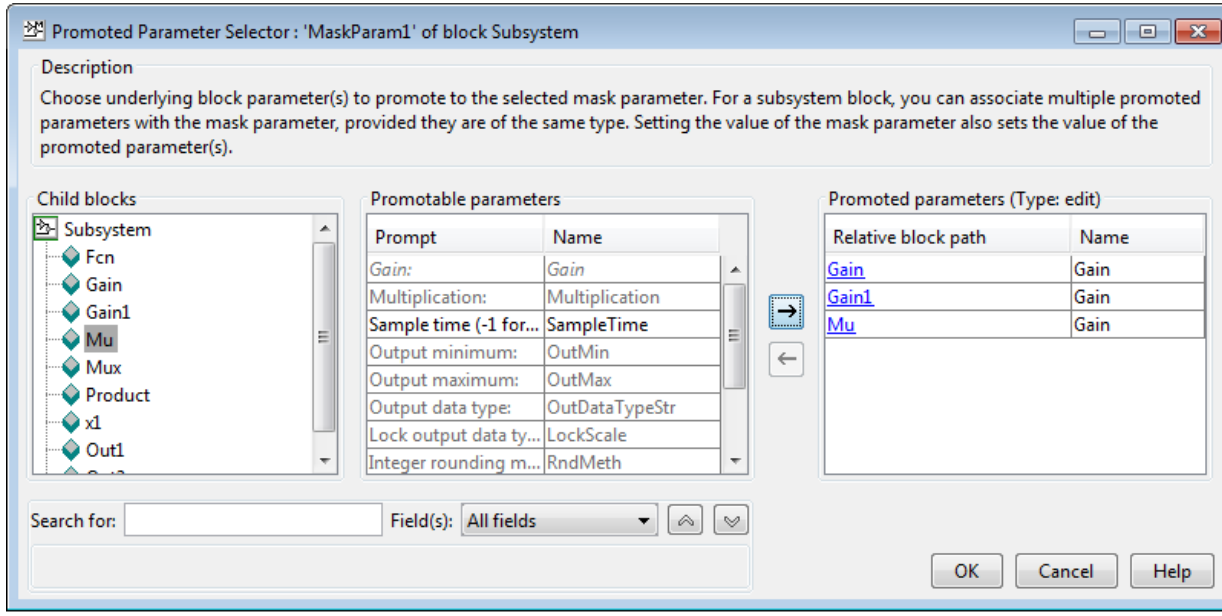
3 In the **Controls** pane, click **Promote**.

4 In the **Property editor** pane, next to **Type options**, click .

5 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.

6 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

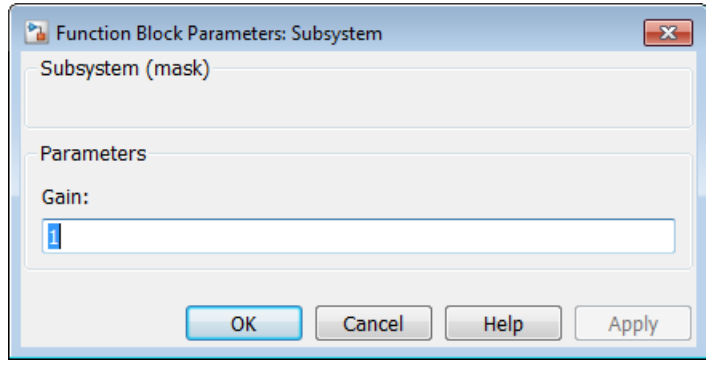
You can add parameters of the same data type, from different child blocks, to the **Promoted parameters** list. For example, the Gain parameter from different child block can be added to the **Promoted parameters** list to promote to the single Gain parameter on the mask.



7 Click **OK**.

8 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.

9 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.



Best Practices

- Set the value of a promoted parameter only in the mask dialog box and not in the underlying block dialog box or from the command line.
- Promote a parameter only once. You cannot promote a parameter from one mask to another.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. User-defined callbacks are sequentially executed after the dynamic dialog callback execute.

"Block Masks" | "Masking Fundamentals" on page 36-2 | "Design Parameter Interface for Reusable Components" on page 34-18

Control Masks Programmatically

In this section...
"Use Simulink.Mask and Simulink.MaskParameter" on page 36-36
"Use `get_param` and `set_param`" on page 36-37
"Programmatically Create Mask Parameters and Dialogs" on page 36-38

Simulink defines a set of parameters that help in setting and editing masks. To set and edit mask from the MATLAB command line, you can use methods of the `Simulink.Mask` and `Simulink.MaskParameter` classes. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode (Non English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` classes to control masks.

Use `Simulink.Mask` and `Simulink.MaskParameter`

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask

1 In this example the `Simulink.Mask.create` method is used to create a block mask:

```
maskObj = Simulink.Mask.create(gcb);
```

```
maskObj =
     Simulink.Mask handle
     Package: Simulink
     Properties:
                  Type: ''
           Description: ''
                  Help: ''
        Initialization: ''
        SelfModifiable: 'off'
```

```
                  Display: ''
                IconFrame: 'on'
               IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
               IconRotate: 'none'
               PortRotate: 'default'
                IconUnits: 'autoscale'
               Parameters: []
  Methods, Events, Superclasses
```

2 In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcb)
```

```
maskObj =
    Simulink.Mask handle
    Package: Simulink
    Properties:
                      Type: ''
               Description: ''
                      Help: ''
            Initialization: ''
            SelfModifiable: 'off'
                   Display: ''
                IconFrame: 'on'
               IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
               IconRotate: 'none'
               PortRotate: 'default'
                IconUnits: 'autoscale'
               Parameters: [1x1 Simulink.MaskParameter]
     Methods, Events, Superclasses
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see Simulink.Mask and Simulink.MaskParameter .

Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcb,'MaskStyleString','edit,edit',..
```

```
'MaskVariables','maskparameter1=@1;maskparameter2=&2;',..
'MaskPromptString','Mask Parameter 1:|Mask Parameter 2:',..
'MaskValues',{'1','2'});

get_param(gcb,'MaskStyleString');

set_param(gcb,'MaskStyles',{'edit','edit'},'MaskVariables',..
'maskparameter1=@1;maskparameter2=&2;','MaskPrompts',..
{'Mask Parameter 1:','Mask Parameter 2:'},..
'MaskValueString','1|2');

get_param(gcb,'MaskStyles');
```

where

- `|` separates individual string values for the mask parameters
- `@` indicates that the parameter field is evaluated
- `&` indicates that the parameter field is not evaluated but assigned as a string

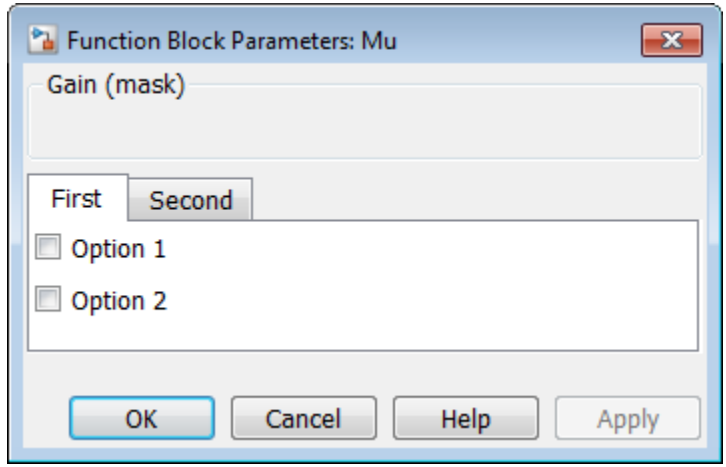
---

Note: When you use `get_param` to get the `Value` of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog but not applied are not reflected when you use the `get_param` command.

To control the mask properties programmatically for a release before R2014a, see Mask Parameters.

Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.



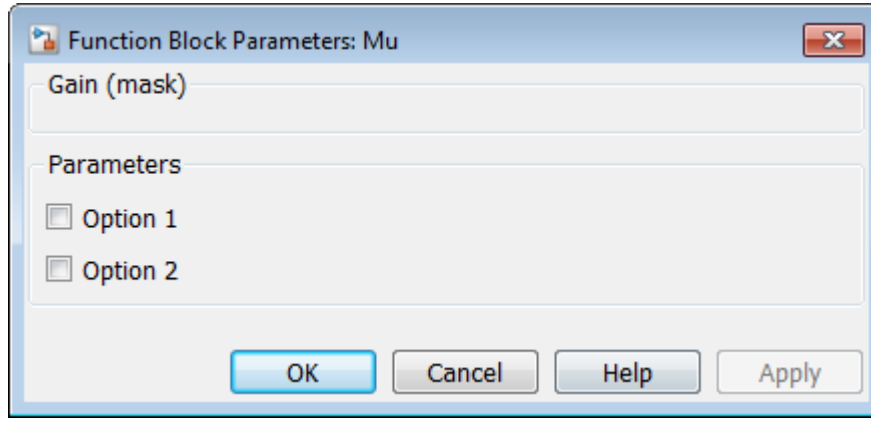
1. Create the mask for a block you selected in the model.

   ```
   maskobj = Simulink.Mask.create(gcb);
   ```

2. Create parameters for the mask. You can change the location of these parameters on the dialog in a subsequent step.

   ```
   maskobj.addParameter('Type','checkbox','Prompt','Option 1',...
   'Name','option1');
   maskobj.addParameter('Type','checkbox','Prompt','Option 2',...
   'Name','option2');
   ```

   These commands create a mask dialog with the default layout. Simulink adds the two parameters to the Parameters group, which is internally named as `ParameterGroupVar` by default.



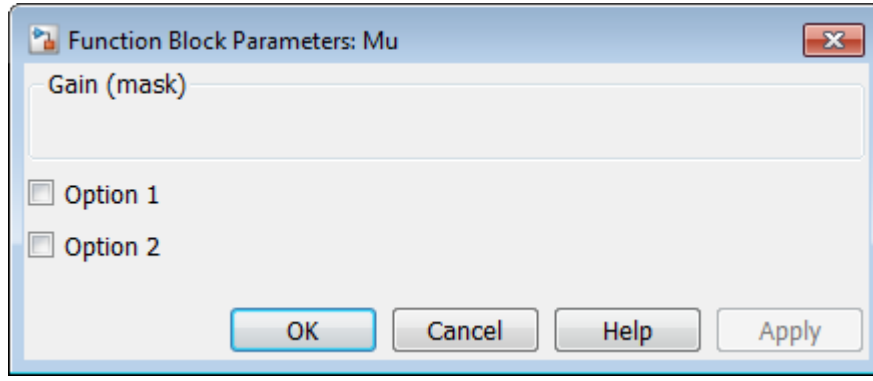
You can verify the group name programmatically.

```
dlg = maskobj.getDialogControls();
dlg(2)
```

```
ans =
  Group with properties:
     Name: 'ParameterGroupVar'
     Prompt: 'Simulink:studio:ToolBarParametersMenu'
     Row: 'new'
     Enabled: 'on'
     Visible: 'on'
    DialogControls: [1x1 Simulink.dialog.parameter.CheckBox]
```

3 To customize the dialog and to use tabs instead of the default group, remove the Parameters group box.

```
maskobj.removeDialogControl('ParameterGroupVar');
```



Simulink preserves the child dialog controls, the two check boxes in this example, even when you delete the `ParametersGroupVar` group surrounding them. This is because these controls are parameters, which cannot be deleted using the dialog control methods.

You can delete parameters using methods such as Simulink.Mask.removeAllParameters, which belongs to the Simulink.Mask class.

4 To create tabs, first create a tab container and get its handle.

```
tabgroup = maskobj.addDialogControl('tabcontainer','tabgroup');
```

5 Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab','tab1');
tab1.Prompt = 'First';
tab2 = tabgroup.addDialogControl('tab', 'tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab','tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off'
```

```
tab3 =

  Tab with properties:

              Name: 'tab3'
```

```
             Prompt: 'Third (invisible)'
            Enabled: 'on'
            Visible: 'on'
    DialogControls: []
```

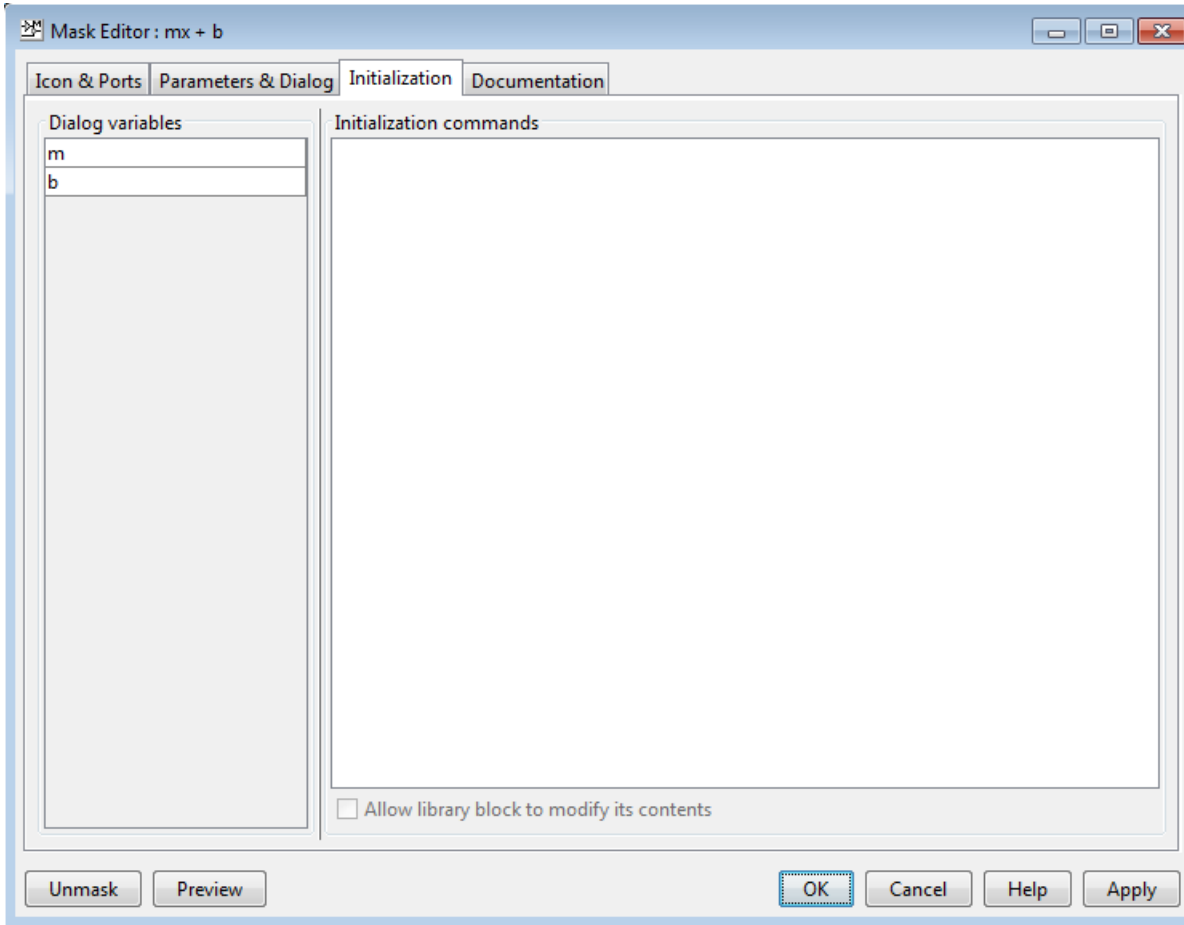
Pass Values to Blocks Under the Mask

The `masking_example` assigns the values input using the mask dialog box directly to block parameters underneath the mask, as described in "Masking Fundamentals" on page 36-2. The assignment occurs because the block parameter and the mask parameter have the same name, so the search that always occurs when a block parameter needs a value finds the mask parameter value automatically, as described in "Symbol Resolution" on page 4-97.

You can use the Mask Editor to insert any desired calculation between a value in the mask dialog box and an underlying block parameter

See the "Initialization Pane" reference for reference information about all **Initialization** pane capabilities. This section shows you how to use it for calculating block parameter values.

To calculate a value for a block parameter, first break the link between the mask and block parameters by giving them different names. To facilitate such changes, the Dialog variables subpane lists all mask parameters.



You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

You can use the initialization code for a masked block to link mask parameters indirectly to block parameters. In this approach, the initialization code creates variables in the mask workspace whose values are functions of the mask parameters and that appear in expressions that set the values of parameters of blocks concealed by the mask.

If you need both the string entered and the evaluated value, clear the **Evaluate** option. To get the value of a base workspace variable entered as the literal value of the mask

parameter, use the MATLAB `evalin` command in the mask initialization code. For example, suppose the user enters the string `'gain'` as the literal value of the mask parameter `k` where `gain` is the name of a base workspace variable. To obtain the value of the base workspace variable, use the following command in the initialization code for the mask:

```
value = evalin('base', k)
```

These values are stored in variables in the *mask workspace*. A masked block can access variables in its mask workspace. A workspace is associated with each masked subsystem that you create. The current values of the subsystem's parameters are stored in the workspace as well as any variables created by the block's initialization code and parameter callbacks.

To use a masked subsystem in a referenced model that uses model arguments, do not create in the mask workspace a variable that derives its value from a mask parameter. Instead, use blocks under the masked subsystem to perform the calculations for the mask workspace variable.

Masks on Blocks in User Libraries

In this section...
“About Masks and User-Defined Libraries” on page 36-46
“Masking a Block for Inclusion in a User Library” on page 36-46
“Masking a Block that Resides in a User Library” on page 36-46
“Masking a Block Copied from a User Library” on page 36-47

About Masks and User-Defined Libraries

You can mask a block that is included in a user library or already resides in a user library, or you can mask an instance of a user library block that you have copied into a model. For example, a user library block might provide the capabilities that a model needs, but its native interface might be inappropriate or unhelpful in the context of the particular model. Masking the block could give it a more appropriate user interface.

Masking a Block for Inclusion in a User Library

You can create a custom block by encapsulating a block diagram that defines the block's behavior in a masked subsystem and then placing the masked subsystem in a library. You can also apply a mask to any other type of block that supports masking, then include the block in a library.

Masking a block that is later included in a library requires no special provisions. Create the block and its mask as described in this section, and include the block in the library as described in “Create a Custom Library” on page 38-3.

Masking a Block that Resides in a User Library

Creating or changing a library block mask immediately changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that already exist as separate copies.

To apply or change a library block mask, open the library that contains the block. Apply, change, or remove a mask as you could if the block did not reside in a library. In addition, you can specify non-default values for block mask parameters. When the block is referenced within or copied into a model, the specified default values appear on

the block's mask dialog box. By default, edit fields have a value of zero, check boxes are cleared, and drop-down lists select the first item in the list. To change the default for any field:

1. Fill in the desired default values or change check box or drop-down list settings
2. Click **Apply** or **OK** to save the changed values into the library block mask.

Be sure to save the library after changing the mask of any block that it contains. Additional information relating to masked library blocks appears in “Create a Custom Library” on page 38-3.

To view related example, see Use self-modifying library masks.

Masking a Block Copied from a User Library

A block that was copied from a user library, as distinct from a block accessed by using a library reference, has no special status with respect to masking. You can add a mask to the copied block, or change or remove any mask that it already has.

Masking Linked Blocks

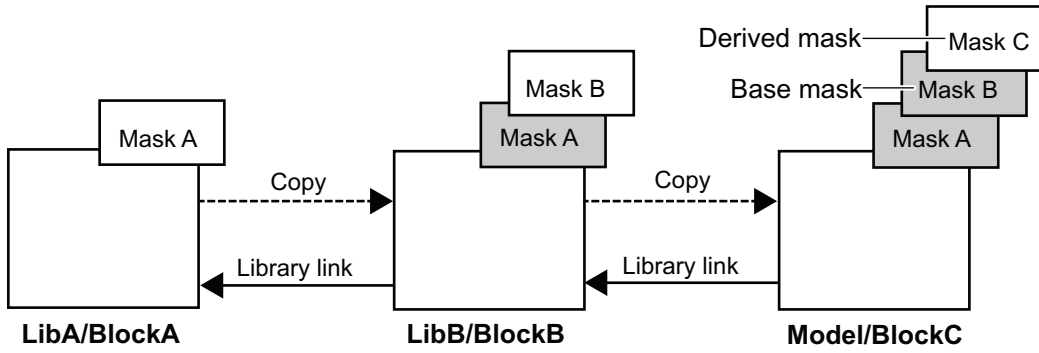
In this section...
“Guidelines for Mask Parameters” on page 36-49
“Mask Behavior for Masked, Linked Blocks” on page 36-50
“How to Mask a Linked Block” on page 36-50

Simulink libraries can contain blocks that have masks. An example of this type of block is the `Ramp` block. These blocks become library links when copied to a model or another library. You can add a new mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Library B to Block C. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.



Note that for Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.
- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the `Promote` type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- Mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- Mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **File > Export Model to > Previous Version**, the `Sourceblock` parameter is modified to point to the library block having the bottom most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
  - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
  - If you break the link to the library block, the block becomes a standalone block.
  - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

How to Mask a Linked Block

Step 1: Create a Custom Library With Mask on Link Block

1. In **Simulink Library Browser**, click the arrow next to and select **New Library**. The Library editor window opens.
2. Open the `Ramp` block in the Library editor window.
3. Right-click the `Ramp` block and select **Mask > Create Mask**.

The **Mask Editor** opens.

4 In the **Icon drawing commands** section of the **Icons & Ports** pane, type;

```
plot ([0:10],[0,1:10])
```

5 In the **Parameter & Dialog** pane, select **Promote** to promote the `Slope` and `Initial Output` parameters.

6 Click **OK**.

7 Rename the block to Derived Ramp Block.

Step 2: Add a Mask to the Masked, Link Block

1 In **Simulink Library Browser**, click the arrow next to and select **New Model**. The Model editor window opens.

2 Drag the Derived Ramp Block from the Library editor to the Model editor.

The Derived Ramp Block in the model has multiple masks on it. You can set parameters of the derived mask.

Step 3: View Masks Below the Top Mask

- Right click the Derived Ramp Block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

Dynamic Mask Dialog Box

In this section...
“About Dynamic Masked Dialog Box” on page 36-52
“Show Parameter” on page 36-53
“Enable Parameter” on page 36-53
“Create Dynamic Mask Dialog Box” on page 36-53
“Setting Nested Masked Block Parameters” on page 36-54

About Dynamic Masked Dialog Box

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include

- Visibility of parameter controls

  Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls

  Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values

  Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

Creating a dynamic masked dialog box entails using the Mask Editor in combination with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Callback Code Execution” on page 36-18). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 36-53). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see Create dynamic mask dialog boxes.

Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: `2`, `5`, or `User-defined`. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

1. Mask a subsystem by right-clicking the block and selecting **Mask** > **Create Mask**.
2. Select the **Parameters & Dialog** pane on the Mask Editor.
3. Drag and drop a **Popup** parameter and select it in the Dialog box pane.
   - In the **Prompt** field, enter `Gain`.
   - In the **Name** field, enter `gainpopup`.
   - In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
   - In the **Type options** field, click the edit button to enter the following three values in the Popup Options dialog box:

     ```
     2
     5
     User-defined
     ```
4. Enter the following code in the **Dialog callback** field:

   ```
   % Get the mask parameter values. This is a cell
   ```

```
%   array of strings.
maskStr = get_param(gcb,'gainpopup');

% The pop-up menu is the first mask parameter.
%   Check the value selected in the pop-up
if strcmp(maskStr(1),'U'),

    % Set the visibility of both parameters on when
    %   User-defined is selected in the pop-up.

    set_param(gcb,'MaskVisibilities',{'on';'on'}),

else

    % Turn off the visibility of the Value field
    %   when User-defined is not selected.

    set_param(gcb,'MaskVisibilities',{'on';'off'}),

    % Set the string in the Values field equal to the
    % string selected in the Gain pop-up menu.

    %maskStr{2}=maskStr{1};
    set_param(gcb,'editvalue',maskStr);
end
```

5 Drag and drop an **Edit** parameter and select it in the Dialog box pane.

- In the **Prompt** field, enter `Value`.
- In the **Name** field, enter `editvalue`.
- In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.

6 Click **Apply**.

7 Double-click the masked subsystem to open the mask dialog box.

If you select `2` or `5` as the **Gain**, Simulink hides the **Value**. If you select `User-defined` as the **Gain** the **Value** is visible.

Setting Nested Masked Block Parameters

Avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying to set

parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems. Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains the command

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

Dynamic Masked Subsystem

In this section...
“Allow Library Block to Modify Its Contents” on page 36-56
“Create Self-Modifying Masks for Library Blocks” on page 36-56
“Evaluate Blocks Under Self-Modifying Mask” on page 36-60

Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcb, 'MaskSelfModifiable', 'on');
```

Then save the block.

Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

1. Unlock the library (see “Lock and Unlock Libraries” on page 38-6).
2. Right-click the block in the library.
3. Select **Mask > Edit Mask**. The Mask Editor opens.

4. In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.
5. Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

   Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see "Adding Mask Code" on page 36-17). Doing so triggers an error when a user edits the parameter.
6. Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.
7. Lock the library.

Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

1. Unlock the library using the following command:

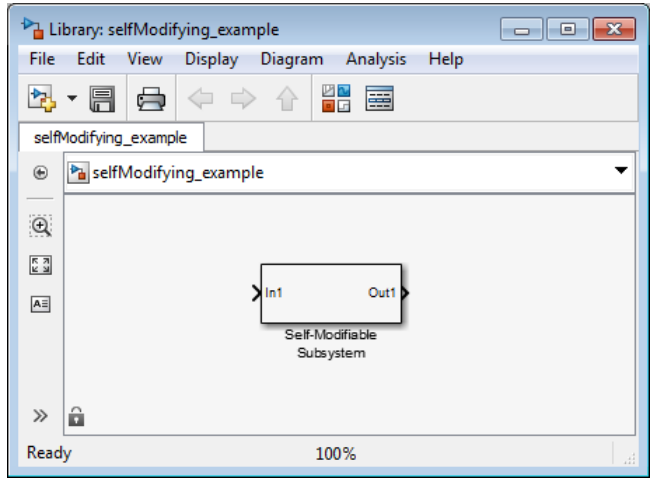
   ```
   set_param(gcs,'Lock','off')
   ```
2. Specify that the block is self-modifying by using the following command:

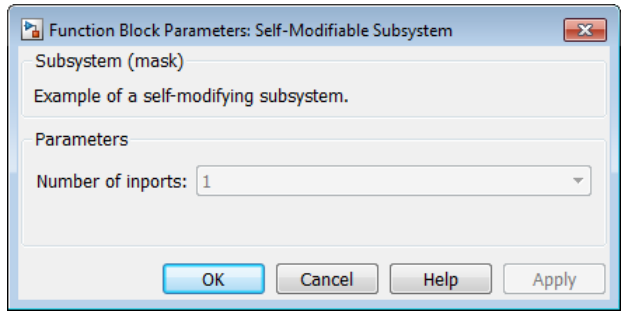
   ```
   set_param(block_name,'MaskSelfModifiable','on')
   ```

   where `block_name` is the full path to the block in the library.

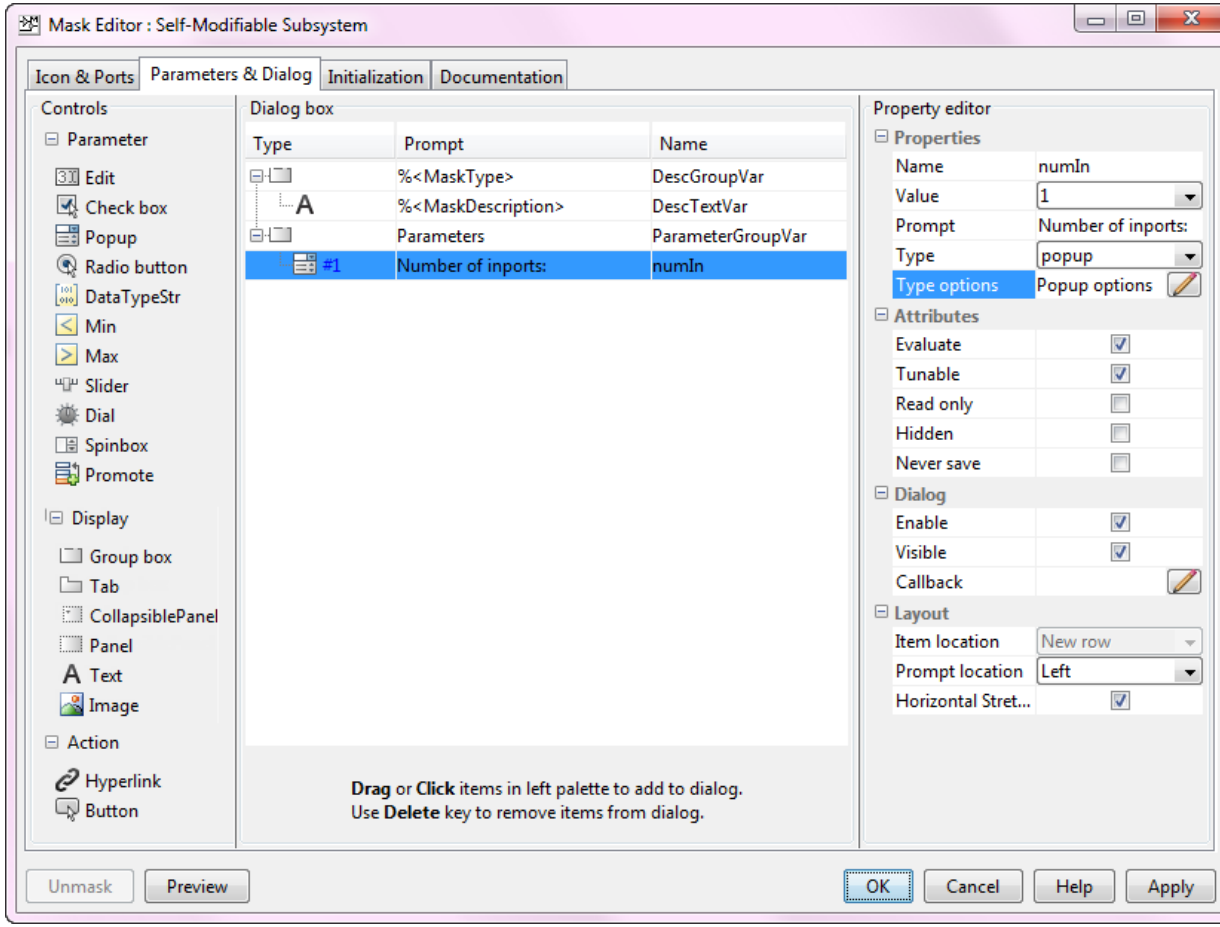
Self-Modifying Mask Example

The library selfModifying_example contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

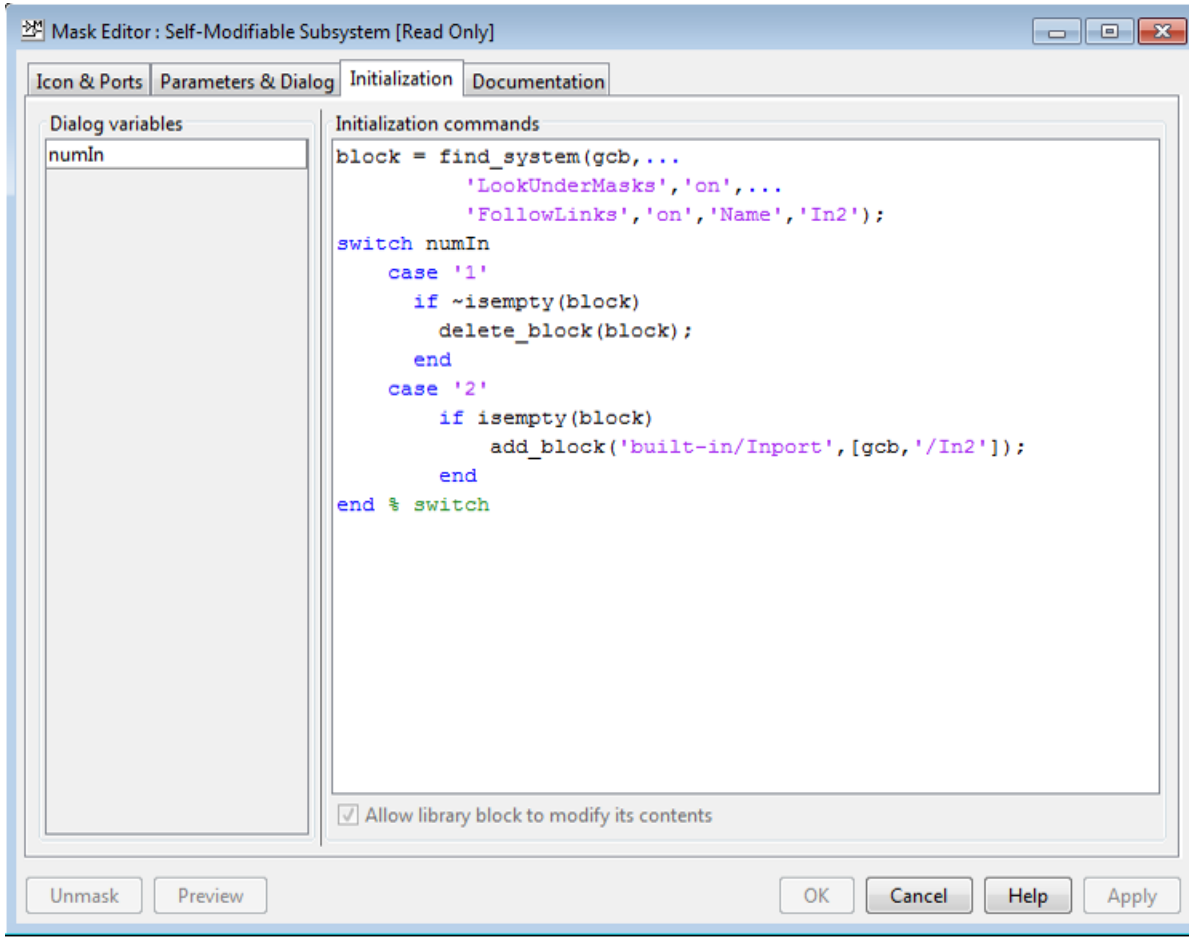




Right-click the subsystem then select **Mask > Edit Mask**. The Mask Editor opens. The Mask Editor **Parameters & Dialog** pane defines a parameter `numIn` that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.



To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option were not selected, copies of the library block could not modify their structural contents and changing the selection in the **Number of inports** list would produce an error.



Evaluate Blocks Under Self-Modifying Mask

This example shows how to force Simulink to evaluate blocks inside self-modifying masks.

Simulink evaluates elements of models containing masks in the following order:

1. Mask dialog box
2. Mask initialization code

3 Blocks or masked subsystems under the mask

Consider the following case:

A block named `myBlock` inside subsystem `mySubsys` masked by a self-modifying mask depends on mask parameter `myParam` to update itself.

`myParam` is exposed to the user through the **Mask Parameters** dialog box. `mySubsys` is updated through MATLAB code written in the **Mask Initialization** pane.

In this model, the sequence of updates is as follows:

1 You modify `myParam` through the mask dialog box.

2 The mask initialization code receives this change and modifies `mySubsys` under the mask.

3 `myBlock`, which lies under `mySubsys`, modifies itself based on the change to `myParam`.

In this sequence, Simulink does not evaluate `myBlock`, which lies under `mySubsys`, when the mask initialization code executes. Instead, Simulink only evaluates and updates the masked subsystem `mySubsys`. Meanwhile, `myBlock` remains unmodified.

You can force Simulink to evaluate such blocks earlier by using the `Simulink.Block.eval` method in the initialization code of the masked subsystem.

```
Simulink.Block.eval('mySubsys/myBlock');
```

Debug Masks That Use MATLAB Code

In this section...
“Code Written in Mask Editor” on page 36-62
“Code Written Using MATLAB Editor/Debugger” on page 36-62

Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor in one of the following ways:

- Remove the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Place a `keyboard` command in the code to stop execution and give control to the keyboard.

Code Written Using MATLAB Editor/Debugger

Note: You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

More About

- “Initialize Mask” on page 36-25
- “Mask Code Execution” on page 36-17

Masking Example Models

The Simulink Masking Example models help understand and configure mask parameters, properties, and features. Notice that the examples of similar type are grouped. In an example model,

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Types of Custom Blocks

In this section...
"MATLAB Function Blocks" on page 37-2
"MATLAB System Blocks" on page 37-2
"Subsystem Blocks" on page 37-3
"S-Function Blocks" on page 37-3
"Masked Blocks" on page 37-5

MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The `Fcn` block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.
- The `Interpreted MATLAB Function` block allows you to use a MATLAB function to define a SISO block.
- The `MATLAB Function` block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing `MATLAB Function` blocks, whereas you cannot generate code for models containing an `Fcn` block.

MATLAB System Blocks

A `MATLAB System` block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object™ that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

1. Masking the block to hide the block contents and provide a custom block dialog box.
2. Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Libraries” and “Block Masks”.

S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The `Level-2 MATLAB S-Function` block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The `S-Function` block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “C/C++ S-Functions”.)
- The `S-Function Builder` block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “C/C++ S-Functions”.)
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”.)

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” in the Simulink Coder User's Guide for details and limitations on using the S-function target.

Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC-file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 44-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

Using S-Function Blocks to Incorporate Legacy Code

Each S-function block allows you to incorporate legacy code into your model, as follows.

- A MATLAB S-function accesses legacy code through its TLC-file. Therefore, the legacy code is available only in the generated code, not during simulation.

- A C MEX S-function directly calls legacy C or C++ code.
- The S-Function Builder generates a wrapper function that calls the legacy C or C++ code.
- The Legacy Code Tool generates a C MEX S-function to call the legacy C or C++ code, which is optimized for embedded systems. See “Integrate C Functions Using Legacy Code Tool” for more information.

See “About External Code Integration” in the Simulink Coder User's Guide for more information.

See “S-Functions Incorporate Legacy C Code” in the Simulink Developing S-Functions for an example.

Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Block Masks”.

Comparison of Custom Block Functionality

In this section...
“Custom Block Considerations” on page 37-6 “Modeling Requirements” on page 37-10 “Speed and Code Generation Requirements” on page 37-13

Custom Block Considerations

When creating a custom block, consider the following.

- Does the custom block need multiple input and output ports?
- Does the block model continuous or discrete state behavior?
- Do the block inputs and outputs have various data attributes, such as data types or complexity?
- How important is the effect of the custom block on the speed of updating the Simulink diagram or simulating the Simulink model?
- Do you need to generate code for a model containing the custom block?

The following two tables provide an overview of how each custom block type addresses the previous questions. More detailed information for each consideration follows these two tables.

Modeling Requirements

Custom Block Type	Supports Multiple Inputs and Outputs	Models State Dynamics	Supports Various Data Attributes
Subsystem	Yes, including bus signals.	Yes.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
`Fcn`	No. Must have a single vector input and scalar output.	No.	Supports only real scalar signals with a data type of double or single.

Custom Block Type	Supports Multiple Inputs and Outputs	Models State Dynamics	Supports Various Data Attributes
`Interpreted MATLAB Function`	No. Must have a single vector input and output.	No.	Supports only n-D, real, or complex signals with a data type of double.
`MATLAB Function`	Yes, including bus signals.	No.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
`MATLAB System`	Yes, including bus signals.	Yes.	Yes, including all data types (except buses and enumerated), numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
Level-2 MATLAB S-function	Yes.	Yes, including limited access to other S-function APIs.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
C MEX S-function	Yes, including bus signals if using the Legacy Code Tool to generate the S-function.	Yes, including full access to all S-function APIs.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.

Speed and Code Generation Requirements

Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
Subsystem	Proportional to the complexity of the subsystem. For library blocks, can be slower the first time the library is loaded.	Proportional to the complexity of the subsystem. Library blocks introduce no additional overhead.	Natively supported.

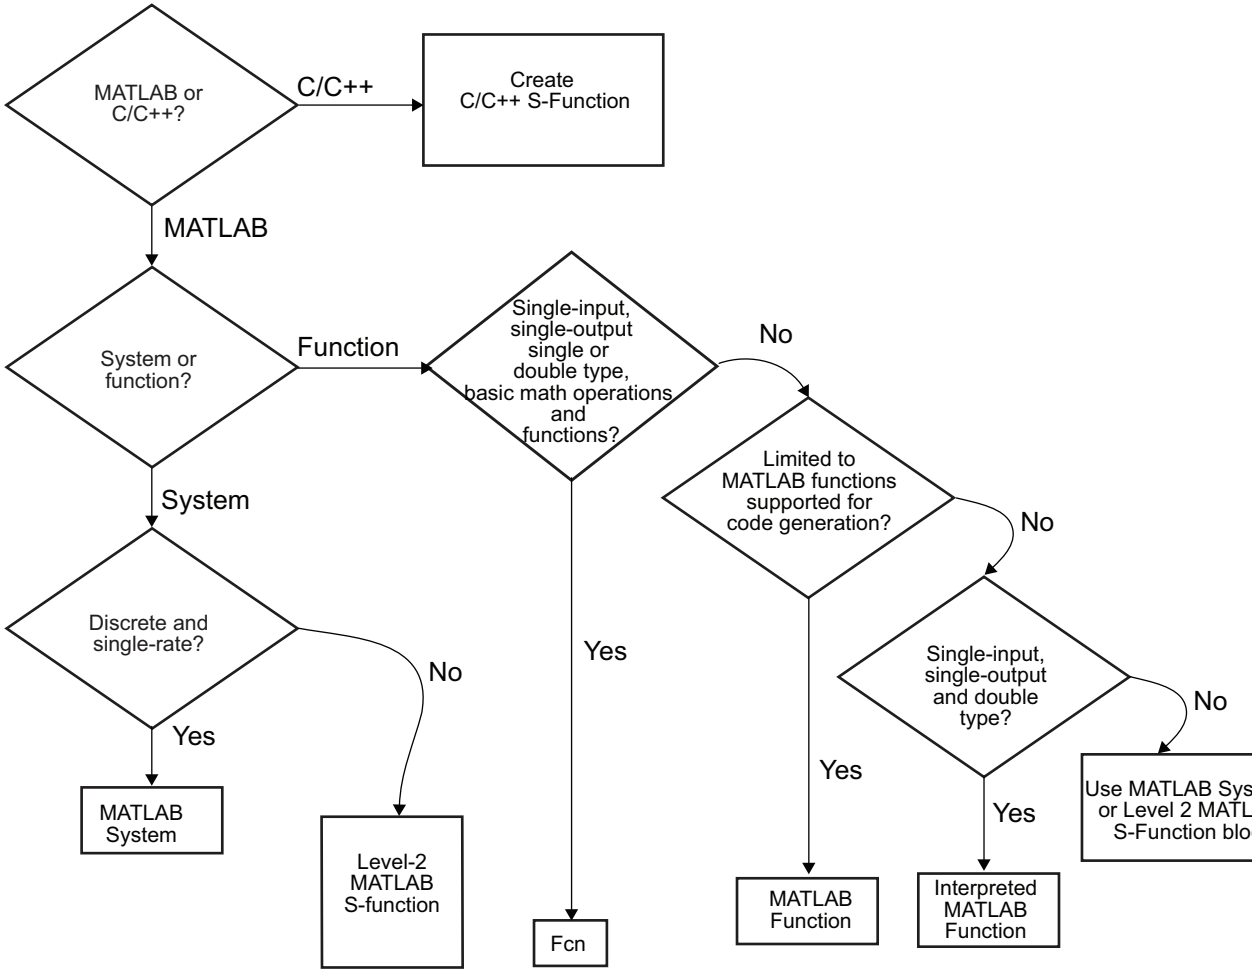
Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
`Fcn`	Very fast.	Minimal, but these blocks also provide limited functionality.	Natively supported.
`Interpreted MATLAB Function`	Fast.	High and incurred when calling out to the MATLAB execution engine. Avoid these calls if simulation speed is a concern.	Not supported.
`MATLAB Function`	Can be slower if code must be generated to update the diagram.	Minimal if the MATLAB execution engine is not called. Simulation speed is equivalent to C MEX S-functions when the MATLAB execution engine is not called.	Natively supported, with exceptions. See "Code Generation" on page 37-16 for more information.
`MATLAB System`	Faster than `MATLAB Function` because code is not generated to update the diagram.	In interpreted execution mode, the simulation has the overhead of calling the MATLAB execution engine. In code generation mode, the first simulation incurs code generation overhead. However, in subsequent runs, the block simulation speed is equivalent to C MEX S-functions.	Natively supported, with exceptions.
Level-2 MATLAB S-function	Can be slower if the S-function overrides methods executed when updating the diagram.	Higher than for `Interpreted MATLAB Function` blocks because the MATLAB execution engine is called for every S-function method used.	MATLAB S-functions initialized as a `SimViewingDevice` do not generate code. Otherwise, MATLAB S-functions require a TLC-file for code generation.

Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
		Very flexible, but very costly.	
C MEX S-function	Can be slower if the S-function overrides methods executed when updating the diagram.	Minimal, but proportional to the complexity of the algorithm and the efficiency of the code.	Might require a TLC-file.

Block Type Flowchart

The diagram shows how to decide which block to use. One deciding factor is whether you need the block for a function or a system. In this context:

- A function defines the relationship between a set of inputs and outputs.
- A system defines the relationship between a set of inputs and outputs. It can also define a set of states, parameters, and System object processing methods for initialization, output, update, termination, and so forth.



Modeling Requirements

Multiple Input and Output Ports

The following types of custom blocks support multiple input and output ports.

Custom Block Type	Multiple Input and Output Port Support
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See "Self-Modifying Linked Subsystems" on page 38-15 for more information.
`Fcn`, `Interpreted MATLAB Function`	Supports only a single input and a single output port. Use a `Mux` block to combine the inputs and a `Demux` block to separate the outputs if you pass multiple signals into or out of these blocks.
`MATLAB Function`	Supports multiple input and output ports, including bus signals. See "How Structure Inputs and Outputs Interface with Bus Signals" on page 39-77 for more information.
`MATLAB System`	Supports multiple input and output ports, including bus signals. See "Define System Objects" for more information.
S-function (MATLAB or C MEX)	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. S-functions generated using the Legacy Code Tool also accept Simulink bus signals. See "Integrate C Functions Using Legacy Code Tool" for more information.

State Behavior and the S-Function API

Simulink blocks communicate with the Simulink engine through the S-function API, a set of methods that fully specifies the behavior of blocks. Each custom block type accesses a different set of the S-function APIs, as follows.

Custom Block Type	S-Function API Support
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the Continuous and Discrete Simulink block libraries.
`Fcn`, `Interpreted MATLAB Function`, `MATLAB Function`	All create a `mdlOutputs` method to calculate the value of the outputs given the value of the inputs. You cannot access any other S-function API methods using one of these blocks and, therefore, cannot model state behavior.

Custom Block Type	S-Function API Support
`MATLAB System`	Uses System object methods for S-function APIs: `mdlOutputs` (`stepImpl`, `outputImpl`), `mdlUpdate` (`updateImpl`), `mdlInitializeConditions` (`resetImpl`), `mdlStart` (`setupImpl`), `mdlTerminate` (`releaseImpl`).
MATLAB S-function	Accesses a larger subset of the S-function APIs, including methods you can use to model continuous and discrete states. For a list of supported methods, see "Level-2 MATLAB S-Function Callback Methods" in "Writing S-Functions".
C MEX S-function	Accesses the complete set of S-function APIs.

Data Attribute Support

All custom block types support real scalar inputs and outputs with a data type of double.

Custom Block Type	Data Attribute Support
Subsystem	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
`Fcn`	Supports only double or single data types. In addition, the input and output cannot be complex and the output must be a scalar signal. Does not support frame-based signals.
`Interpreted MATLAB Function`	Supports 2-D, n-D, and complex signals, but the signal must have a data type of double. Does not support frame-based signals.
`MATLAB Function`	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
`MATLAB System`	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
S-function (MATLAB or C MEX)	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.

Speed and Code Generation Requirements

Updating the Simulink Diagram

The Simulink software updates the diagram before every simulation and whenever requested by the user. Every block introduces some overhead into the "update diagram" process.

Custom Block Type	Speed of Updating the Diagram
Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when the Simulink software loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, the Simulink software does not subsequently reload the library and compiling the model becomes faster than if the model did not use libraries.
`Fcn`, `Interpreted MATLAB Function`	Does not incur greater update cost than other Simulink blocks.
`MATLAB Function`	Performs simulation through code generation, so these blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
`MATLAB System`	Faster than `MATLAB Function` because code is not generated to update the diagram. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
S-function (MATLAB or C MEX)	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in "Simulink Engine Interaction with C S-Functions". When updating the diagram, the Simulink software invokes all relevant methods in the model initialization phase up to, but not including, `mdlStart`.

Simulation Overhead

For most applications, any of the custom block types provide acceptable simulation performance. Use the Simulink profiler to obtain an indication of the actual performance. See“How Profiler Captures Performance Data” on page 28-5 for more information.

You can break simulation performance into two categories. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Simulation Overhead
Subsystem	If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.
`Fcn`	Has the least simulation overhead. The block is tightly integrated with the Simulink engine and implements a rudimentary expression language that is efficiently interpreted.
`Interpreted MATLAB Function`	Has a higher interface cost than most blocks and the same algorithm cost as a MATLAB function. When block data (such as inputs and outputs) is accessed or returned from an `Interpreted MATLAB Function` block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as, frames or arrays, this overhead can be substantial. Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function. Efficient code can be competitive with C code if MATLAB is able to optimize it, or if the code uses the highly optimized MATLAB library functions.
`MATLAB Function`	Performs simulation through code generation and so incurs the same interface cost as standard blocks. The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and a MATLAB function run at about the same speed. To reduce the algorithm cost, you can disable debugging for all the `MATLAB Function` blocks. If the `MATLAB Function` block uses simulation-only capabilities to call out to the MATLAB execution engine, it incurs all the costs that

Custom Block Type	Simulation Overhead
	a MATLAB S-function or `Interpreted MATLAB Function` block incur. Calling out to the MATLAB execution engine from a `MATLAB Function` block produces a warning to prevent you from doing so unintentionally.
`MATLAB System`	Performs simulation through one of the following: • Interpreted execution, the model simulates the block using the MATLAB execution engine. • Code generation, the model simulates the block using generated code. For more information, see the `MATLAB Function` entry in this table.
MATLAB S-function	Incurs the same algorithm costs as the `Interpreted MATLAB Function` block, but with a slightly higher interface cost. Because MATLAB S-functions can handle multiple inputs and outputs, the packaging is more complicated than for the `Interpreted MATLAB Function` block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement whereas for the `Interpreted MATLAB Function` block, it calls the MATLAB execution engine only for the `mdlOutputs` method.
C MEX S-function	Simulates via the compiled code and so incurs the same interface cost as standard blocks. The algorithm cost depends on the complexity of the S-function.

Code Generation

Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Code Generation Support
Subsystem	Supports code generation.
`Fcn`	Supports code generation.
`Interpreted MATLAB Function`	Does not support code generation.
`MATLAB Function`	Supports code generation. However, if your `MATLAB Function` block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
`MATLAB System`	Supports code generation. However, if your `MATLAB System` block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
MATLAB S-function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-function in interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-function is a `SimViewingDevice`, the Simulink Coder product automatically omits the block during code generation.
C MEX S-function	Supports code generation. For noninlined S-functions, the Simulink Coder product uses the C MEX function during code generation. However, you must write a TLC-file for the S-function if you need to either inline the S-function or create a wrapper for hand-written code. See “S-Functions and Code Generation” in the Simulink Coder User's Guide for more information.

Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and Handle Graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Create Block Callbacks” on page 4-77.

GUIDE, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” for more information on using GUIDE.

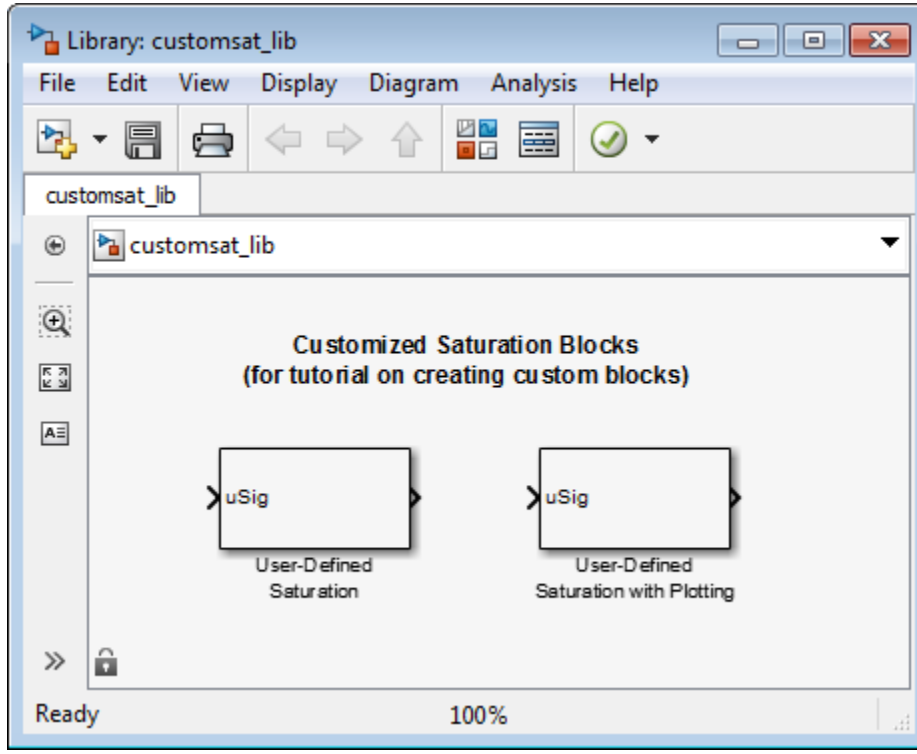
How to Design a Custom Block

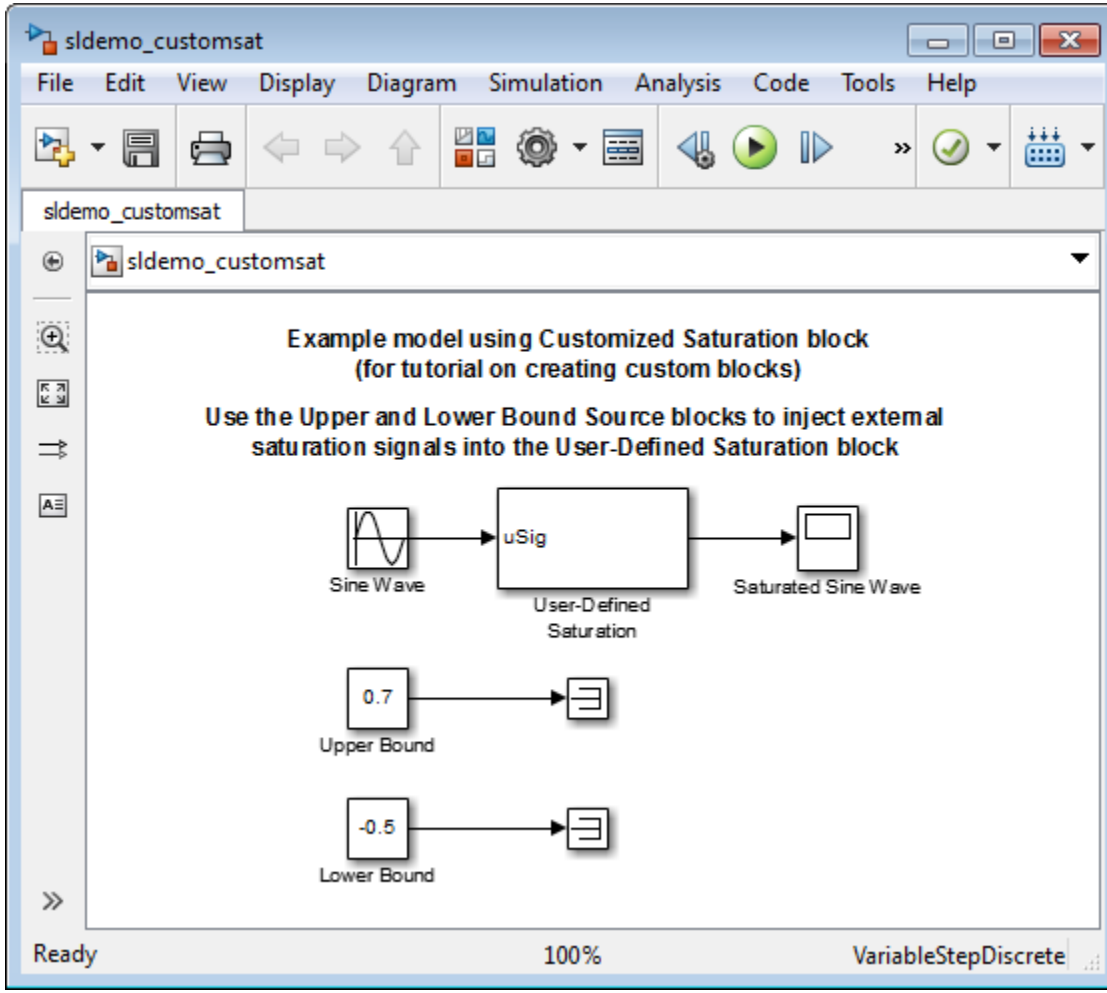
In general, use the following process to design a custom block:

1. “Defining Custom Block Behavior” on page 37-21
2. “Deciding on a Custom Block Type” on page 37-22
3. “Placing Custom Blocks in a Library” on page 37-26
4. “Adding a User Interface to a Custom Block” on page 37-29

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `customsat_lib` contains the two versions of the customized saturation block.



The example model `sldemo_customsat` uses the basic version of the block.



Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.

- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 37-6 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template msfuntmpl.m provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file custom_sat.m. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID  = 0;  % double
```

```
block.InputPort(1).Complexity  = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID  = 0; % double
block.OutputPort(1).Complexity  = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms     = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----------------------------------------------------------------
%% Options
%% -----------------------------------------------------------------
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----------------------------------------------------------------
%% Register methods called during update diagram/compilation
%% -----------------------------------------------------------------

block.RegBlockMethod('CheckParameters',      @CheckPrms);
block.RegBlockMethod('ProcessParameters',    @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs',              @Outputs);
block.RegBlockMethod('Terminate',            @Terminate);
%end setup function
```

- The `CheckParameters` method verifies the values entered into the Level-2 MATLAB S-Function block.

```
function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal  = block.DialogPrm(2).Data;
upMode  = block.DialogPrm(3).Data;
upVal   = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end
```

```
if ~any(lowMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

% If the upper or lower bound is specified via a dialog, make sure there
% is a specified bound. Also, check that the value is of type double
if isequal(upMode,2),
    if isempty(upVal),
        error('Enter a value for the upper saturation limit.');
    end
    if ~strcmp(class(upVal), 'double')
        error('The upper saturation limit must be of type double.');
    end
end

if isequal(lowMode,2),
    if isempty(lowVal),
        error('Enter a value for the lower saturation limit.');
    end
    if ~strcmp(class(lowVal), 'double')
        error('The lower saturation limit must be of type double.');
    end
end

% If a lower and upper limit are specified, make sure the specified
% limits are compatible.
if isequal(upMode,2) && isequal(lowMode,2),
    if lowVal >= upVal,
        error('The lower bound must be less than the upper bound.');
    end
end

%end CheckPrms function
```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```
function ProcessPrms(block)

%% Update run time parameters
block.AutoUpdateRuntimePrms;

%end ProcessPrms function

function DoPostPropSetup(block)

%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;

%end DoPostPropSetup function
```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
lowPortNum = 2; % Initialize potential input number for lower saturation limit

% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3), % Set via an input port
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

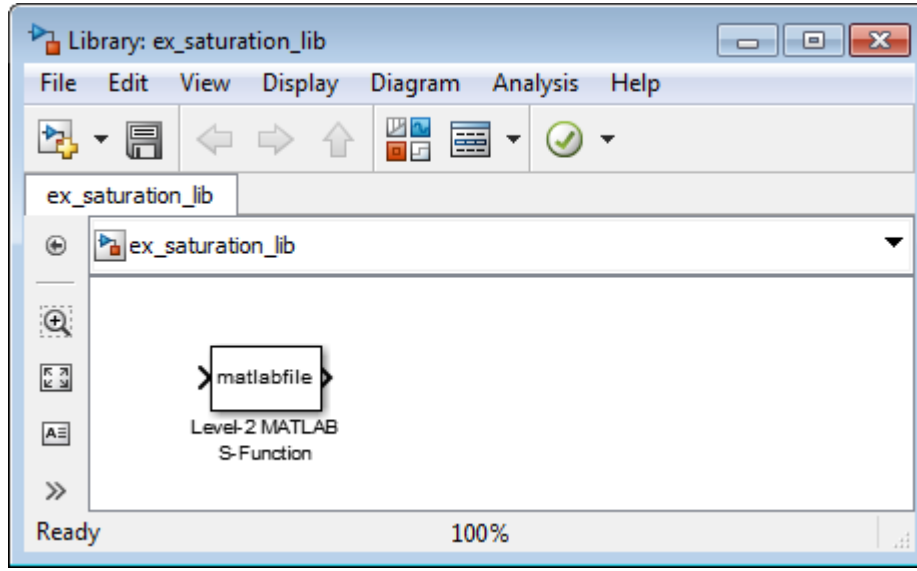
block.OutputPort(1).Data = sigVal;

%end Outputs function
```

Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. This example places the custom saturation block into a library.

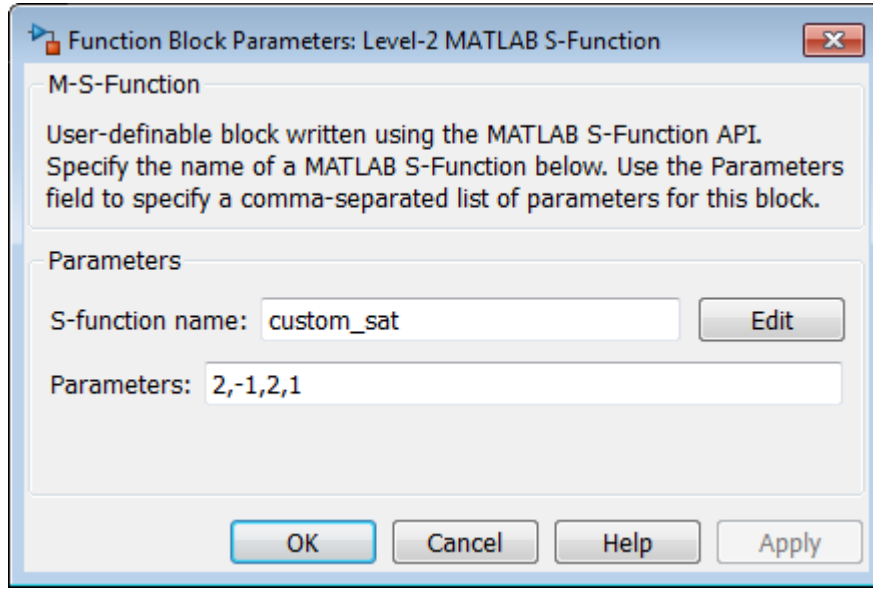
1. In the Simulink Library Browser, select **File > New > Library**.
2. From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.



3 Save your library with the filename `saturation_lib`.

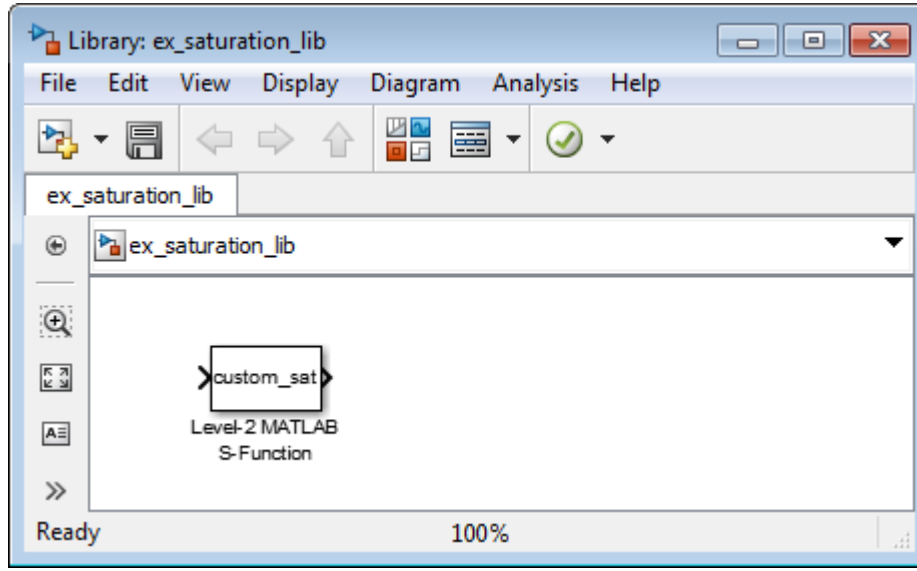
4 Double-click the block to open its Function Block Parameters dialog box.

5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2,-1,2,1`.



6 Click **OK**.

You have created a custom saturation block that you can share with other users.



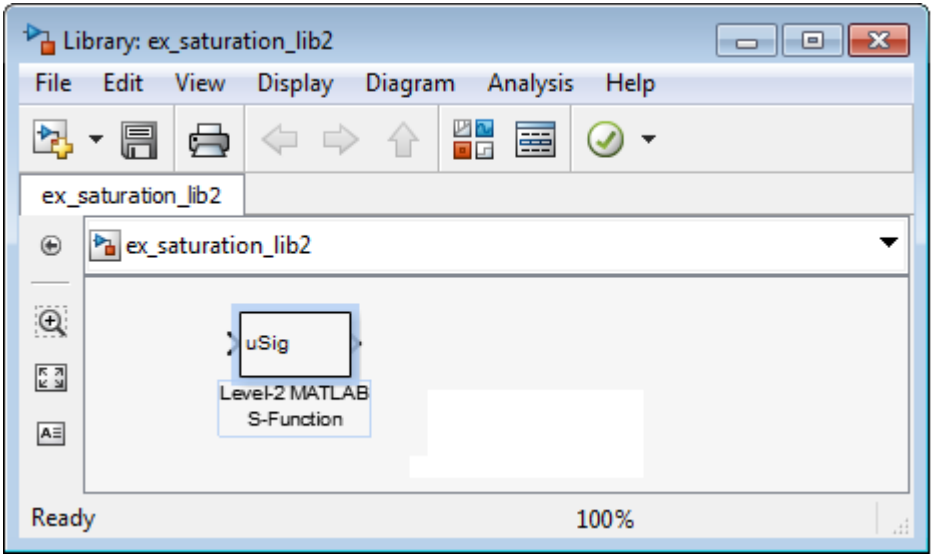
You can make the block easier to use by adding a customized user interface.

Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

1. Open the library `saturation_lib` that contains the custom block you created,
2. Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
3. On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

   This command labels the default port as the input signal under saturation.



4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

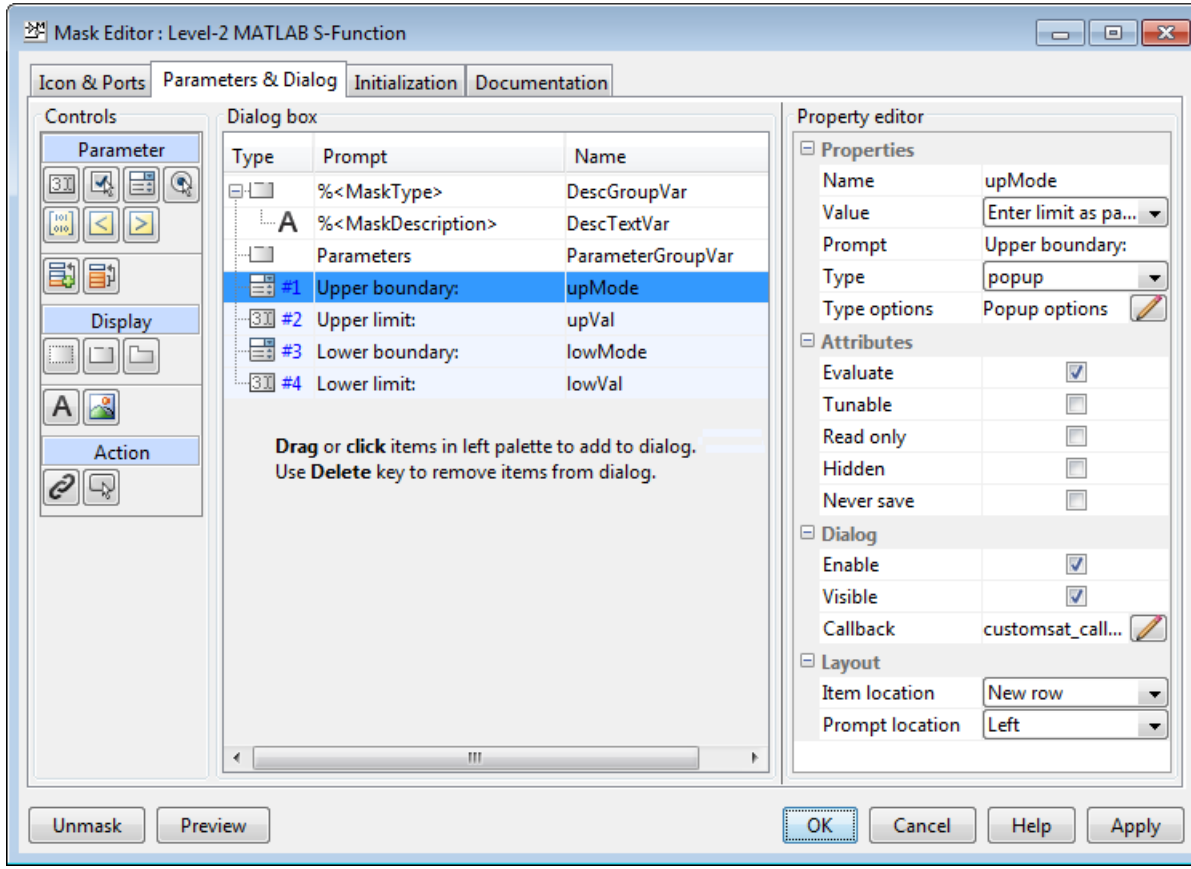
Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callba gcb)
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callba gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary	lowMode	✓		No limit	customsat_callback('lowerbound_callba gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
					Enter limit as parameter Limit using input signal	
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callb gcb)

The MATLAB S-Function script custom_sat_final.m contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a string indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.



5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.

6 In the **Documentation** pane:

- In the **Mask type** field, enter

  ```
  Customized Saturation
  ```

- In the **Mask description** field, enter

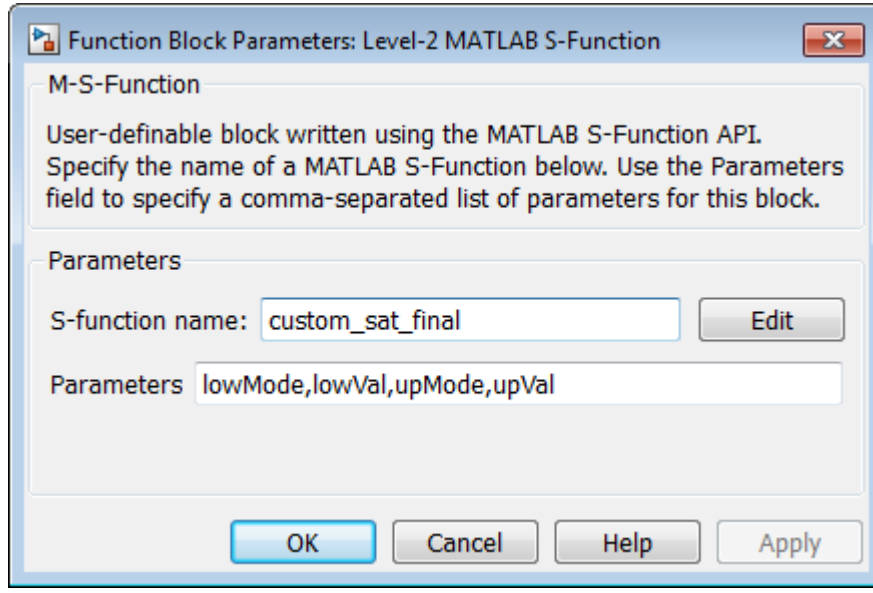
  ```
  Limit the input signal to an upper and lower saturation value
  set either through a block parameter or input signal.
  ```

7 Click **OK**.

8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.

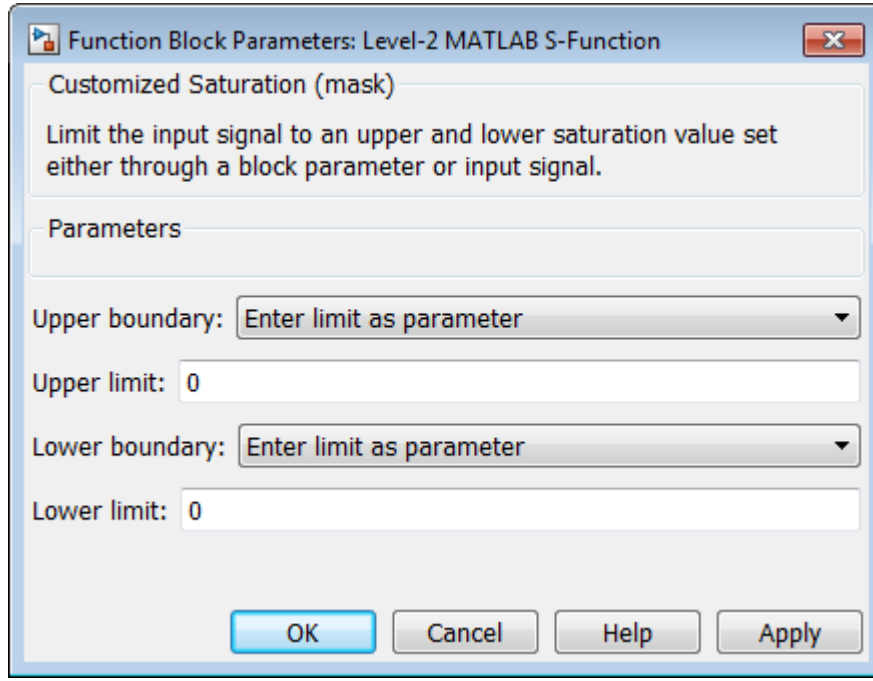
9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.



10 Click **OK**. Save and close the library to exit the edit mode.

11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.



To create a more complicated user interface, place a Handle Graphics user interface on top of the masked block. The block `OpenFcn` invokes the Handle Graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

Writing the Mask Callback

The function customsat_callback.m contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block,'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisbilities`. This call returns a cell array of strings indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label string.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

%   Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label(''input'',1,''uSig'')'};
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label(''input'',2,''up'')'}];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{['port_label(''input'',',num2str(length(portStr)+1), ...
        ',''low'')']}];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function custom_sat_final.m contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```
%% Function: setup ===============================================
```

```
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID  = 0;  % double
block.InputPort(1).Complexity  = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID  = 0; % double
block.OutputPort(1).Complexity  = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms     = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----------------------------------------------------------------
%% Options
%% -----------------------------------------------------------------
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----------------------------------------------------------------
%% Register methods called during update diagram/compilation
%% -----------------------------------------------------------------

block.RegBlockMethod('CheckParameters',      @CheckPrms);
block.RegBlockMethod('ProcessParameters',    @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs',              @Outputs);
block.RegBlockMethod('Terminate',            @Terminate);
%endfunction
```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```
%% Function: Get Port Visibilities =====================================
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end
```

Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

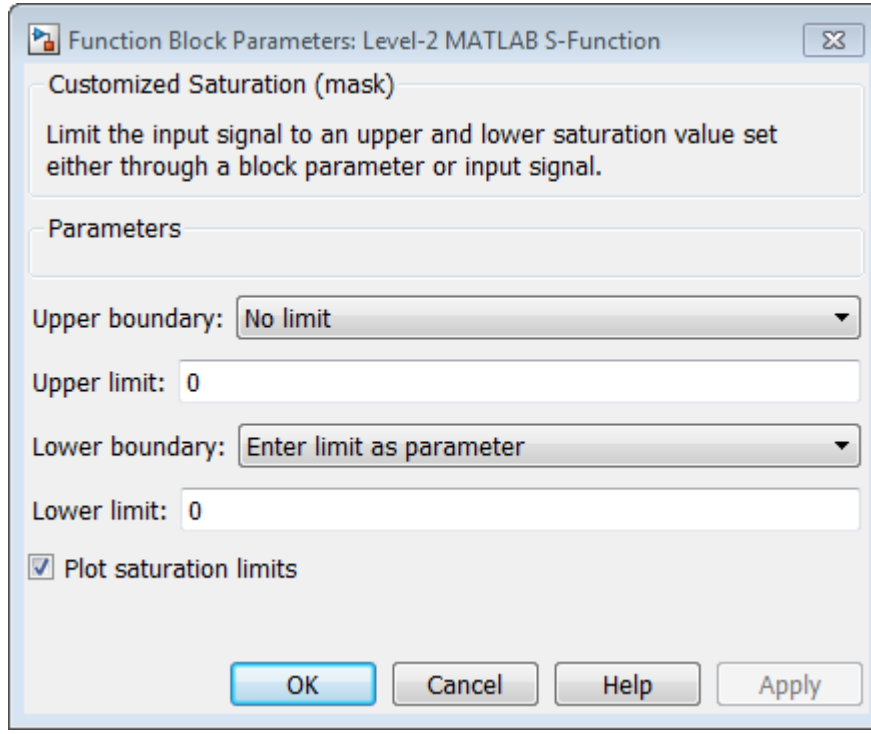
1. Add a check box to the mask parameter dialog box to toggle the plotting option on and off.

    a. Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask+Create Mask**.

    b. On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunable	Type options	Callback
Plot saturatio limits	`plotche`	`checkbo`	No	NA	`customsat_callback('plotsaturatior`

c Click **OK**.



2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```
%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block,'MaskValues');
ud = struct('time',[],'upBound',[],'upVal',[],'lowBound',[],'lowVal',[]);

if strcmp(vals{1},'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3},'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb,'UserData',ud);
```

3 Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```
%% Function: Outputs ===================================================
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
vals = get_param(block.BlockHandle,'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode,2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end
```

```
% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction
```

4 Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```
function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
%   This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end

    % Reinitialize userdata
    ud.upVal=[];
    ud.lowVal=[];
    ud.time = [];
    set_param(block,'UserData',ud);
end
```

5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the `StopFcn` to call the plotting callback as shown in the following figure, then click **OK**.

“Creating Custom Blocks from S-Functions” on page 37-44

Creating Custom Blocks from Masked Library Blocks

The Additional Math and Discrete Simulink library is a group of custom blocks created by extending the functionality of built-in Simulink blocks. The Additional Discrete library contains a number of masked blocks that extend the functionality of the standard Unit Delay block. See “Libraries” for more general information on Simulink libraries.

Creating Custom Blocks from MATLAB Functions

The Simulink product provides a number of examples that show how to incorporate MATLAB functions into a custom block.

- The Single Hydraulic Cylinder Simulation, sldemo_hydcyl, uses a `Fcn` block to model the control valve flow. In addition, the Control Valve Flow block is a library link to one of a number of custom blocks in the library hydlib.
- The Radar Tracking Model, sldemo_radar, uses an `Interpreted MATLAB Function` block to model an extended Kalman filter. The MATLAB function aero_extkalman.m implements the Kalman filter found inside the Radar Kalman Filter subsystem. In this example, the MATLAB function requires three inputs, which are bundled together using a Mux block in the Simulink model.
- The Spiral Galaxy Formation example, sldemo_eml_galaxy, uses several `MATLAB Function` blocks to construct two galaxies and calculate the effects of gravity as these two galaxies nearly collide. The example also uses `MATLAB Function` blocks to plot the simulation results using a subset of MATLAB functions not supported for code generation. However, because these `MATLAB Function` blocks have no outputs, the Simulink Coder product optimizes them away during code generation.

Creating Custom Blocks from System Objects

The Simulink product provides a number of examples that show how to incorporate System objects into a custom block. Access the MATLAB source code for each System object by clicking the `Source code` link from the block dialog box. For more information on using MATLAB System blocks and System objects, see "System Object Integration").

- System Identification for an FIR System Using MATLAB System Blocks, slexSysIdentMATLABSystemExample, uses the `MATLAB System` block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks.
- MATLAB System Block with Variable-Size Input and Output Signals, slexVarSizeMATLABSystemExample, uses the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses System object propagation methods.
- Illustration of Law of Large Numbers Using MATLAB System Blocks, slexLawOfLargeNumbersExample, uses MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses System object propagation methods and interpreted execution.

Creating Custom Blocks from S-Functions

The Simulink model sfundemos contains various examples of MATLAB and C MEX S-functions. For more information on writing MATLAB S-functions, see "Write Level-2 MATLAB S-Functions". For more information on writing C MEX S-functions, see "C/C++ S-Functions". For a list of available S-function examples, see "S-Function Examples" in Writing S-Functions.

Custom Libraries and Linked Blocks

Why Create Custom Libraries?

A *block library* is a collection of blocks that you can use to create instances of those blocks in a Simulink model. You can create instances of blocks from installed Simulink libraries, and you can create custom libraries to create and maintain instances of your own blocks in models.

You can access the installed libraries from the Simulink Library Browser. You cannot modify the installed libraries. Instead, if you want others to be able to create customized blocks, you can create your own library of your blocks and add it to the library browser. Otherwise, you can make your library accessible to the models that use it.

Creating your own libraries is a useful componentization technique for:

- Providing frequently used, and seldom changed, modeling utilities
- Reusing components in a model or in multiple models

To learn how using custom libraries compares to other Simulink componentization techniques, see “Componentization Guidelines” on page 15-29.

How Block Instances Connect to Libraries

When you add masked blocks, subsystems, or charts from a custom library to a model, the block you add becomes a *linked block*. A linked block connects to the library block by way of a *library link*. The library block is the *prototype block*, and the linked block in the model is an *instance* of the library block.

The linked block looks and acts like the library block. However, if you change the library block, you need to update the link on the instances. Making changes to an instance can also require additional steps. To learn about how linked blocks work, see “Create and Work with Linked Blocks” on page 38-13.

Create a Custom Library

In this section...
“Create a Library” on page 38-3
“Blocks for Custom Libraries” on page 38-4
“Lock and Unlock Libraries” on page 38-6
“Prevent Disabling of Library Links” on page 38-7

Create a Library

You can create your own library and, optionally, add it to the Simulink Library Browser. You save a library as a `.SLX` file as you do a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 38-6.

1. From the Simulink start page, select **Blank Library** and click **Create Library**.
2. Add blocks from models or libraries to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

   Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as Subsystem_Name1/Subsystem_Name2/Subsystem_Name1.
3. If you want the library to appear in the library browser, enable the model property `EnableLBRepository` before you save the library.

   ```
   set_param(gcs,'EnableLBRepository','on');
   ```
4. Save the library.

   Where you save the library depends on how you plan to use it. If you want to add it to the library browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the library browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example

that shows complete steps for adding a library to the browser, see “Add Libraries to the Library Browser” on page 38-8.

Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Types of Custom Blocks” on page 37-2.

You can create blocks in custom libraries with settings for specific purposes.

Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a `Subsystem` block in the parent library.

1. In the library you want to add a sublibrary to, add a `Subsystem` block.
2. Inside the `Subsystem` block, delete the default input and output ports.
3. If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary's purpose.
4. In the subsystem's block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 36-6.

Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block's `CopyFcn` callback.

```
set_param(gcbh,'LinkStatus','none');
```

Include Block Description in Linked Block

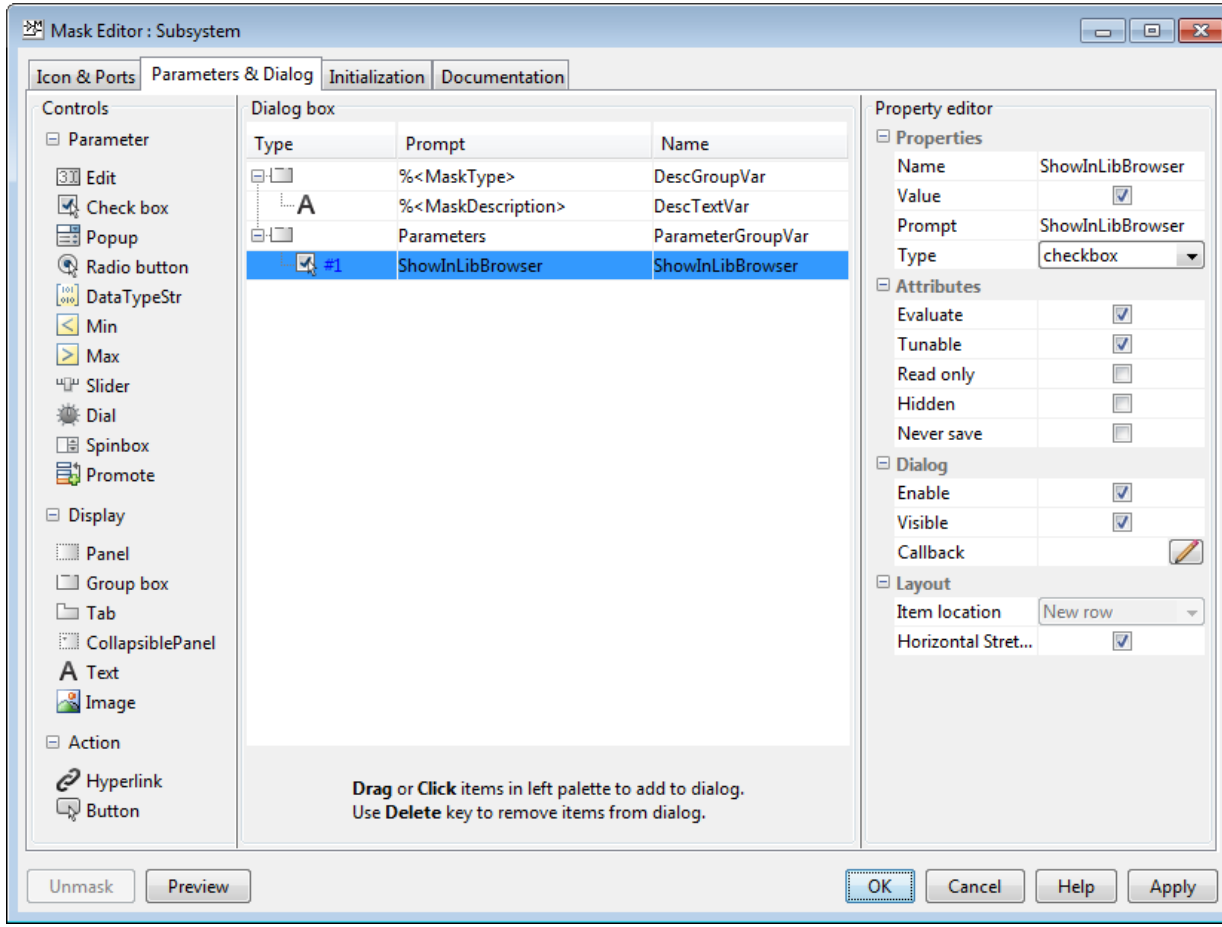
To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

Configure Subsystems with OpenFcn Callback for Library Browser

A common use of a `Subsystem` block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a `Subsystem` block for other purposes, for example to run MATLAB code or to open a link.

If your subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library or model, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

1. Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.
2. In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
3. In the **Dialog box** pane, set the prompt and name for the new check box to `ShowInLibBrowser` and click **OK**.



Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a dialog box prompts you to unlock it.

You can unlock a library programmatically.

```
set_param('library_name','Lock','off');
```

If you unlocked the library programmatically, you must lock it again from the MATLAB command prompt.

```
set_param('library_name','Lock','on');
```

Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, select **Diagram > Lock Links To Library**.

To understand how the block user interacts with blocks from locked libraries, see "Lock Links to Blocks in a Library" on page 38-18.

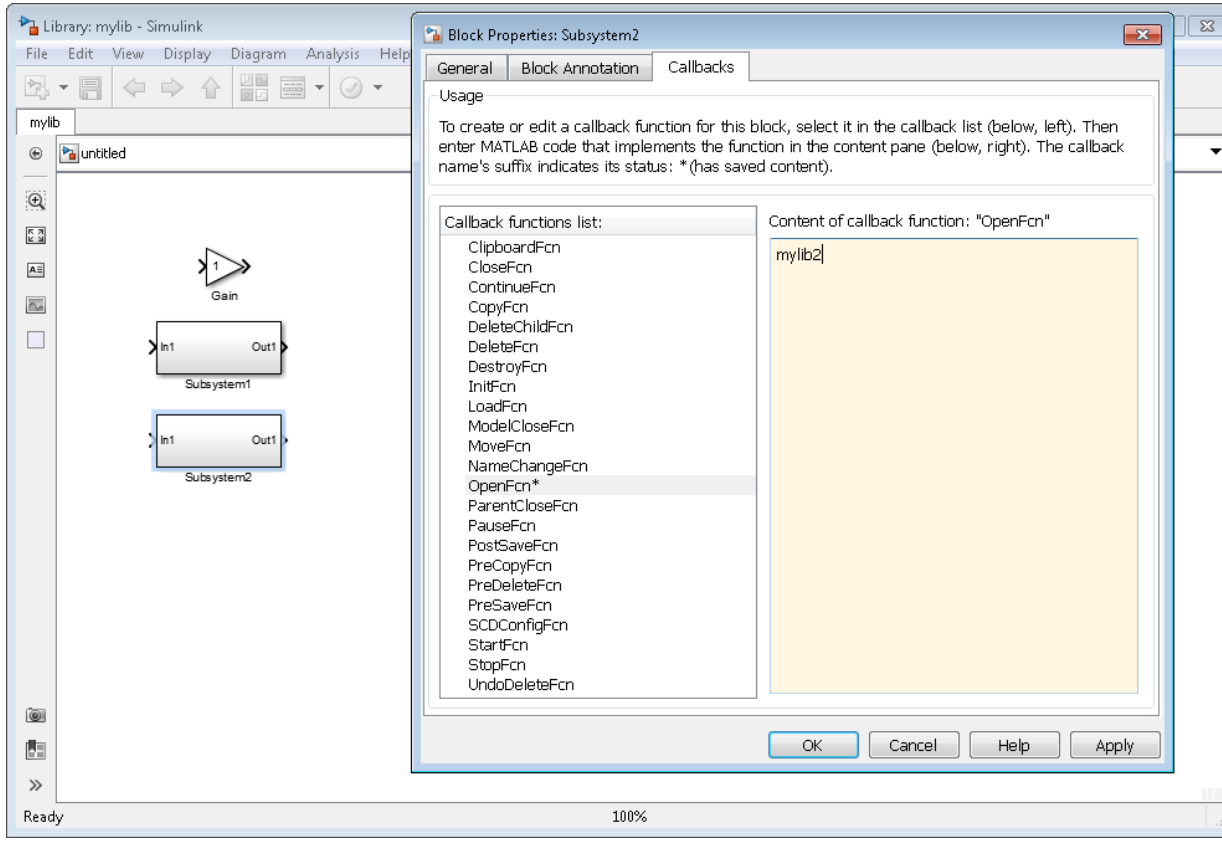
Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink Library Browser. You create a function `slblocks` to specify information about your custom libraries. You can save the function as a `.m` file or `.mlx` file. You cannot save it as a P-code file.

1. From the Simulink start page, select **Blank Library** and click **Create Library**.
2. Add a Gain block and two Subsystem blocks to the library. Name the Subsystem blocks Subsystem1 and Subsystem2. In the Subsystem2 properties, set the `OpenFcn` callback to `mylib2`.



3. At the MATLAB command prompt, enable the model property `EnableLBRepository`. Your library appears in the library browser only if this property is on when you save your library.

   ```
   set_param(gcs,'EnableLBRepository','on');
   ```

4. Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.

5. Create another library `mylib2` and add some blocks to it. Save it to the same folder you saved `mylib` to.

   You can close both libraries if you want.

6. In MATLAB, right-click the folder you saved the library to and select **New File** > **Script**. Name the file `slblocks.m`.

7. Open `slblocks.m`. Add this function to it and save.

   ```
   function blkStruct = slblocks
     % This function specifies that the library should appear
     % in the Library Browser
     % and be cached in the browser repository

     Browser.Library = 'mylib';
     % 'mylib' is the name of the library

     Browser.Name = 'My Library';
     % 'My Library' is the library name that appears in the Library Browser

     blkStruct.Browser = Browser;
   ```

8. In the Library Browser, refresh to see the new library. Right-click the library list and select **Refresh Library Browser**.

   The figure shows the example library `mylib` with the library browser name **My Library**.

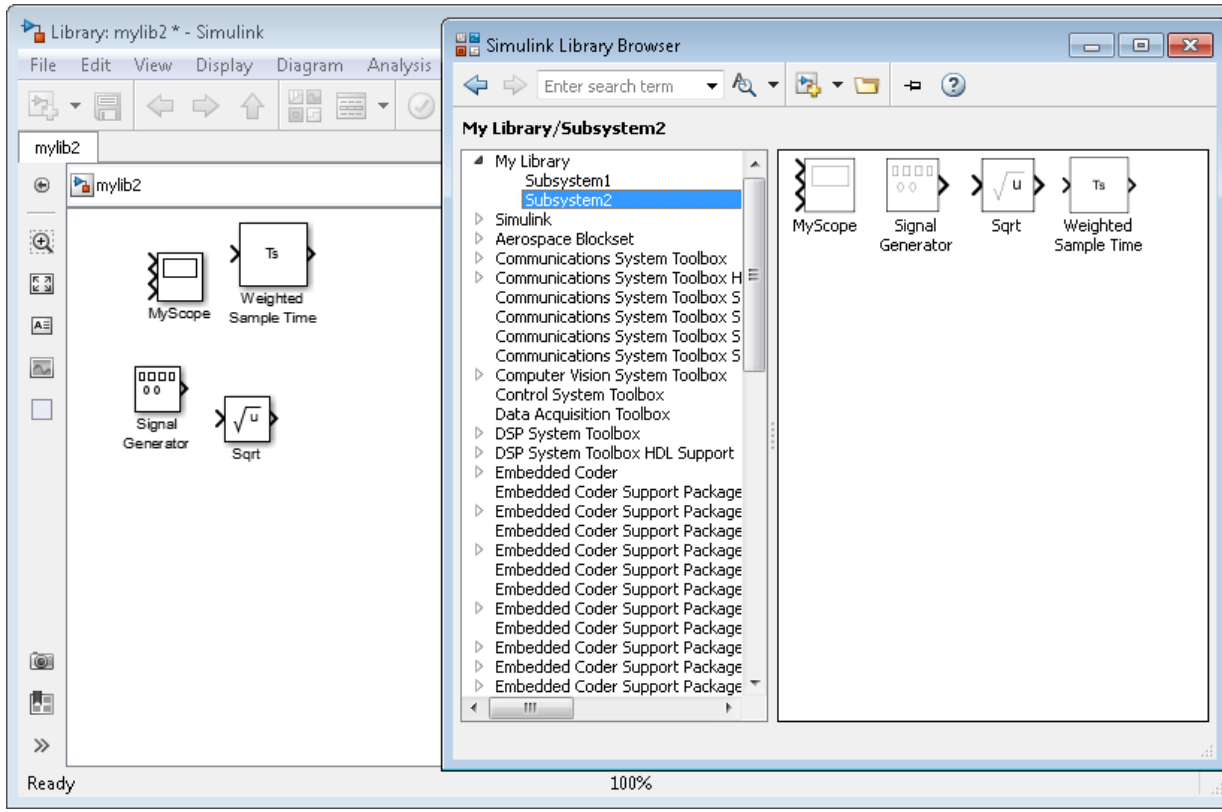
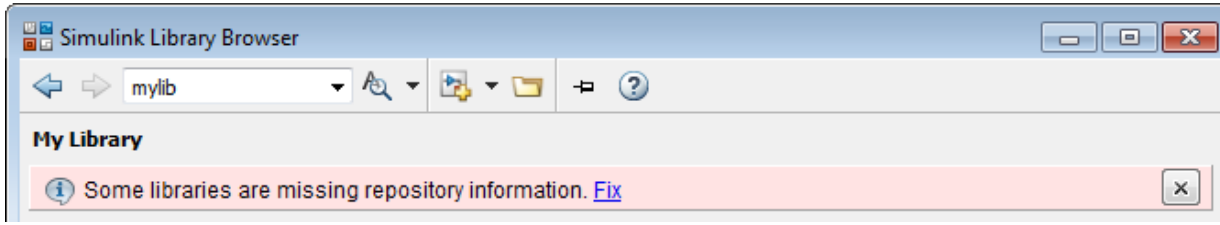
Because of the callback you created, clicking Subsystem2 displays the contents of the `mylib2` library.



Note: If you saved your library without setting `'EnableLBRepository'` to `'on'`, a message appears at the top of the library browser.



Click **Fix** and respond to the prompt as appropriate.

Specify Library Order in the Library List

You can specify the order of your library relative to the other libraries in the list by adding your own `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, enter:

```
sl_refresh_customizations
```

Create and Work with Linked Blocks

In this section...
“About Linked Blocks” on page 38-13
“Create a Linked Block” on page 38-13
“Update a Linked Block” on page 38-14
“Modify Linked Blocks” on page 38-14
“Find a Linked Block’s Prototype” on page 38-15
“Find Linked Blocks in a Model” on page 38-16

About Linked Blocks

A *linked block* is an instance of a library block and contains a link to the library block that serves as the block type’s prototype. The link consists of the path of the library block that serves as the instance's prototype. The link allows the linked block to update whenever the corresponding prototype in the library changes (“Update a Linked Block” on page 38-14). This ensures that your model always uses the latest version of the block.

Note: The tooltip for a linked block shows the name of the library block it references.

You can change the values of a linked block's parameters (including in an existing mask). You cannot add a new mask for linked blocks or edit the mask setup, that is, add or remove mask parameters or change mask behavior.

Also, you cannot set callback parameters for a linked block. If the linked block’s prototype is a subsystem, you can make nonstructural changes to the contents of the linked subsystem (see “Modify Linked Blocks” on page 38-14).

Create a Linked Block

To create a linked block in a model or another library:

1. Open your model.
2. Open the Simulink Library Browser or another library.

3 Use the Library Browser to find the library block that serves as a prototype of the block you want to create.

4 Drag the library block from the Blocks pane to your model.

Update a Linked Block

Simulink updates out-of-date linked blocks in a model or library when you:

- Load the model or library.
- Run the simulation.
- Use the `find_system` command.
- Query the `LinkStatus` parameter of a block, using the `get_param` command (see "Check and Set Link Status Programmatically" on page 38-24).

  Note: Querying the `StaticLinkStatus` parameter of a block does not update any out-of-date linked blocks.

- Save changes to a library block, then Simulink automatically refreshes all links to the block in open Model Editor windows.

When you edit a library block (in the Model Editor or at the command line), then Simulink indicates stale links which are open in the Model Editor by displaying the linked blocks grayed out. Simulink refreshes any stale links to edited blocks when you activate the Model Editor window, even if you have not saved the library yet.

To manually refresh links:

- Select **Simulation > Update Diagram** (or press **Ctrl+D**).
- Select **Diagram > Refresh Blocks** (or press **Ctrl+K**) to refresh links.
- Select **Go To Library Link**.

Modify Linked Blocks

You cannot make structural changes to linked blocks, such as adding or deleting lines or blocks to the block diagram of a masked subsystem. If you want to make such changes, you must disable the linked block's link to its library prototype (see "Disable Links to Library Blocks" on page 38-20).

Parameterized Links

If you change parameter values inside a linked block, you create a *parameterized link*. You can change the values of any masked subsystem linked block parameter that does not alter the block's structure, e.g., by adding or deleting lines, blocks, or ports. An example of a nonstructural change is a change to the value of a mathematical block parameter, such as the Gain parameter of the Gain block. A linked subsystem block whose parameter values of inner blocks differ from their corresponding library blocks is called a *parameterized link*. Changing the top-level mask values does not create a parameterized link.

When saving a model containing a parameterized link, Simulink saves the changes to the local copy of the subsystem together with the path to the library copy in the model's file. When you reopen the system, Simulink copies the library block into the loaded model and applies the saved changes.

Tip To determine whether a linked block's parameter values differ from those of its library prototype, open the linked block's block diagram in an editor window. The linked block's library link indicator (if displayed) changes to a red arrow and the title bar of the editor window displaying the subsystem displays "Parameterized Link" if the linked block's parameter values differ from the library block's parameter values.

See "Display Library Links" on page 38-17.

Self-Modifying Linked Subsystems

Simulink allows linked subsystems to change their own structural contents without disabling the link. This allows you to create masked subsystems that modify their structural contents based on mask parameter dialog box values.

Find a Linked Block's Prototype

To find the source library and the prototype of a linked block, right-click the linked block and select **Library Link > Go To Library Link**.

If the library is open, Simulink selects and highlights the library block and makes the source library the active window. If the library is not open, Simulink first opens it and then selects the library block.

Find Linked Blocks in a Model

Use the `libinfo` command to get information about the linked blocks in the model and which library blocks they link to. The `ReferenceBlock` property gives the path of the library block to which a block links.

Work with Library Links

In this section...
"Display Library Links" on page 38-17
"Lock Links to Blocks in a Library" on page 38-18
"Disable Links to Library Blocks" on page 38-20
"Restore Disabled or Parameterized Links" on page 38-21
"Check and Set Link Status Programmatically" on page 38-24
"Break a Link to a Library Block" on page 38-26
"Fix Unresolved Library Links" on page 38-27

Display Library Links

A model can have a block linked to a library block, or it can have a local instance of a block that is not linked. To enable the display of library links:

1. In the Model Editor window, select **Display > Library Links** and from the submenu, select one of these options:
   a. **None** — displays no links
   b. **Disabled** — displays only disabled links (the default for new models)
   c. **User Defined** — displays only links to user libraries
   d. **All** — displays all links
2. Observe the library link indicators.

   The library link indicator is a badge in the bottom left corner of each block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link. If you open a linked block, the Model Editor displays the same link badge at bottom left. You can right-click the link badge in the corner of the canvas to access link options such as **Go To Library Block**.

Link Badge	Status
Black links	Active link
Gray separated links	Inactive link
Black links with a red star icon	Active and modified (parameterized link)
White links, black background	Locked link

Note: If you have a variant subsystem block inside a link block, modifying the parameters on the variant subsystem creates a link data on the topmost link block. If the link badge is visible, presence of link data is indicated by a red star on the link badge.

Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links enable control of end user editing, to prevent unintentional disabling of these links. This ensures robust usage of mature stable libraries.

To lock links to a library, either:

- In your library window, select **Diagram > Lock Links To Library**.

- At the command line, use the `LockLinksToLibrary` property:

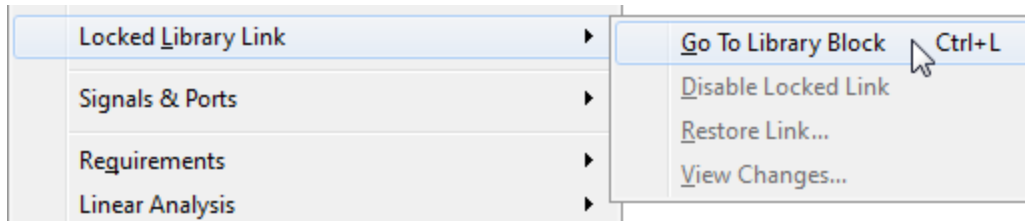
  ```
  set_param('MyModelName', 'LockLinksToLibrary', 'on')
  ```

  where `MyModelName` is the library file.

When you copy a block to a model from a library with locked links:

- The link is locked.
- You cannot disable locked links from the Model Editor.

  If you select **Diagram** or right-click the linked block, you see the **Library Link** menu has changed to **Locked Library Link**, and the only enabled option is now **Go To Library Block**.



- If you display library links, the locked link icon has a black background.

- If you open a locked link, the window title is **Locked Link: *`blockname`***. The bottom left corner shows a lock icon and a link badge.

- You cannot edit locked link contents. If you try to make a structural change to a locked link (such as editing the diagram), you see a message stating that you cannot modify the link because it is either locked or inside another locked link.

  - The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
  - You cannot parameterize locked links in the Model Editor.
- You can disable locked links only from the command line as follows:

  ```
  set_param(gcb, 'LinkStatus', 'inactive')
  ```

To unlock links to a library:

- In your library window, select **Diagram > Unlock Links To Library**
- At the command line:

  ```
  set_param('MyModelName', 'LockLinksToLibrary', 'off')
  ```

  The status of a link (locked or not) is determined by the library state when you copy the block. If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh links.

If you use sublibraries as an organizational tool, when you lock links to a library, you might want also to lock links to any sublibraries.

Disable Links to Library Blocks

To make a structural change to a linked block, you need to disable the link between the block and the library block that serves as its prototype.

You cannot disable *locked* links from the Model Editor. See "Lock Links to Blocks in a Library" on page 38-18.

Note When you use the Model Editor to make a structural change (such as editing the diagram) to a block with an active library link, Simulink offers to disable the library link for you (unless the link is locked). If you accept, Simulink disables the link and allows you to make changes to the subsystem block.

Do not use `set_param` to make a structural change to an active link; the result of this type of change is undefined.

To disable a link:

1. In the Model Editor window, right-click a linked block and select **Library Link > Disable Link**.
2. Alternatively, select a linked block and select the menu item **Diagram > Library Link > Disable Link**.

   The library link is disabled and the library link indicator changes to gray. When a library block is disabled and it is within another library block (a child of a parent library block), the model also disables the parent block containing the child block.

To disable a link from the command-line, set the `LinkStatus` property to `inactive` as follows:

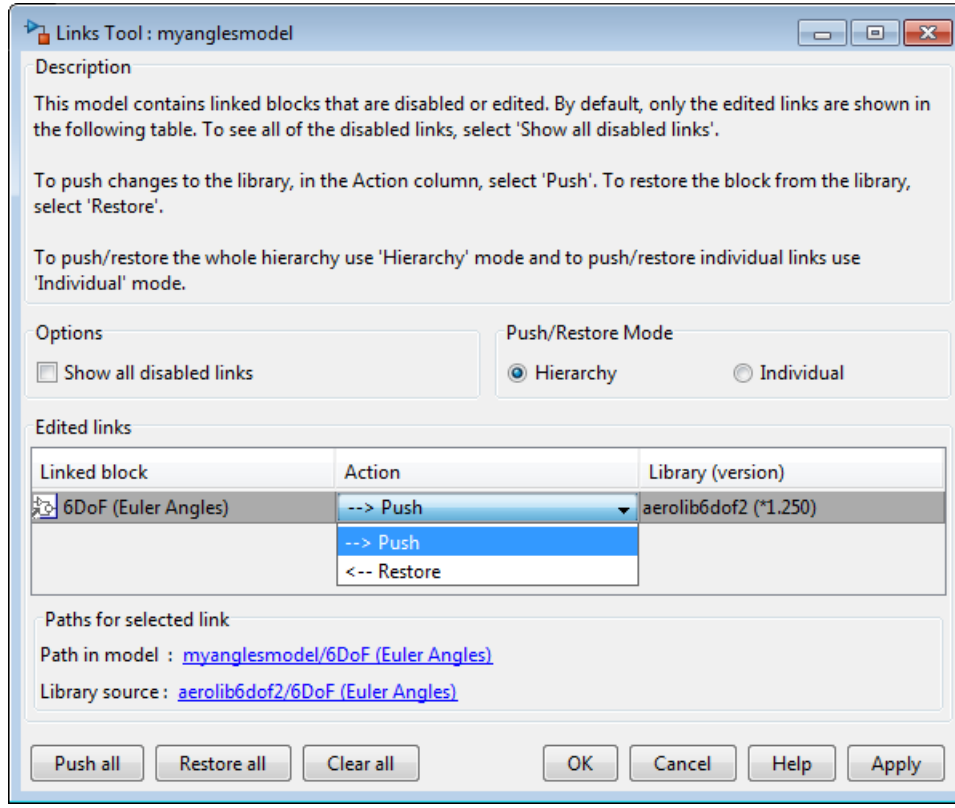
```
set_param(gcb, 'LinkStatus', 'inactive')
```

Restore Disabled or Parameterized Links

After you make changes to a disabled linked block, you may want to restore its link to the library block and resolve any differences between the two blocks. The Links Tool helps you with this task.

1. In the Model Editor window, select a linked block with a disabled library link.
2. From the **Diagram** menu (or right-click context menu), select **Library Link > Resolve Link**.

   The Links Tool window opens.



The **Edited links** table has the following columns:

- **Linked block** — List of linked blocks. The list of links includes library links with structural changes (disabled links), parameterized library links (edited links), and library links that were actively chosen to be resolved.
- **Action** — Select an action to perform on the linked block or library.
- **Library** — List of library names and version numbers.

3 Select the check box **Show all disabled links** if you want to view disabled links as well as parameterized links.

4 Under **Push/Restore Mode**, choose a mode of action:

- If you want to act on individual links, select **Individual**.

- If you want to act on the whole link hierarchy, leave the default setting on **Hierarchy**. See "Pushing or Restoring Link Hierarchies" on page 38-24.

5 From the **Linked block** list, select a block name.

The Links Tool updates the **Paths for selected link** panel with links to the linked block in the model and in the library.

6 From the **Action** list, select **Push** or **Restore** for the currently selected block.

Action Choice	Links Tool Action
`Push`	The Links Tool looks for all changes in the link hierarchy and pushes all links with changes to their libraries. **Push** replaces the version of the block in the library with the version in the model.
`Restore`	The Links Tool looks for all disabled or edited links in the link hierarchy and restores them all with their corresponding library blocks. **Restore** replaces the version of the block in the model with the version in the library.
`Push Individual`	In **Individual** mode, the disabled or edited block is pushed to the library, preserving the changes inside it without acting on the hierarchy. All other links are unaffected.
`Restore Individual`	In **Individual** mode, the disabled or edited block is restored from the library, and all other links are unaffected.

To select the same action for all linked blocks, click **Push all**, **Restore all**, or **Clear all**.

7 When you click **OK** or **Apply**, the Links Tool performs the push or restore actions you selected in the edited links table.

After resolving a link, the versions in the library and the linked block now match.

Note: Changes you push to the library are not saved until you actively save the library.

If a linked block name has a cautionary icon before it, the model has other instances of this block linked from the same library block, and they have different changes. Choose

one of the instances to push changes to the library block and restore links to the other blocks , or choose to restore all of them with the library version.

Pushing or Restoring Link Hierarchies

Caution Be cautious using Push or Restore in hierarchy mode if you have a large hierarchy of edited and disabled links. Ensure that you want to push or restore the whole hierarchy of links.

Pushing a hierarchy of disabled links affects the disabled links inside and outside in the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if without changes. This operation does not affect outside (parent) links with changes unless you also explicitly selected them for push. The Links Tool starts from the lowest links (the deepest inside) and then moves upward in the hierarchy.

Some simple examples:

1. Link A contains link B and both have changes.
   - Push A. The Links Tool pushes both A and B.
   - Push B. The Links Tool pushes B and not A.
2. Link A contains link B. A has no changes, and B has changes.
   - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Links Tool can manipulate only the top level.

Check and Set Link Status Programmatically

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter that indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating out-of-date linked blocks.

Use `get_param` and `set_param` to query and set the `LinkStatus`, which can have the following values.

Get LinkStatus Value	Description
`none`	Block is not a linked block.
`resolved`	Resolved link.
`unresolved`	Unresolved link.
`implicit`	Block resides in library block and is itself not a link to a library block. For example, suppose that A is a link to a subsystem in a library that contains a Gain block. Further, suppose that you open A and select the Gain block. Then, `get_param(gcb, 'LinkStatus')` returns `implicit`.
`inactive`	Disabled link.

Set LinkStatus Value	Description
`none`	Breaks link. Use `none` to break a link, e.g., `set_param(gcb, 'LinkStatus', 'none')`
`inactive`	Disables link. Use `inactive` to disable a link, e.g., `set_param(gcb, 'LinkStatus', 'inactive')`
`restore`	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, `set_param(gcb, 'LinkStatus', 'restore')` replaces the selected block with a link to a library block of the same type, discarding any changes in the local copy of the library block. This is equivalent to `Restore Individual` in the Links Tool.
`propagate`	Pushes any changes made to the disabled link to the library block and re-establishes its link. This is equivalent to `Push Individual` in the Links Tool.
`restoreHierarchy`	Restores all disabled links in the hierarchy with their corresponding library blocks. This is equivalent to `Restore` in hierarchy mode in the Links Tool.
`propagateHierarch`	Pushes all links with changes in the hierarchy to their libraries. This is equivalent to `Push` in hierarchy mode in the Links Tool. See “Restore Disabled or Parameterized Links” on page 38-21.

Note: Using `get_param` to query a block's `LinkStatus` also resolves any out-of-date block links. Use `get_param` to update library links in a model programmatically. Querying the `StaticLinkStatus` property does not resolve any out-of-date links. Query the `StaticLinkStatus` property when the call to `get_param` is in the callback of a child block querying the link status of its parent.

If you call `get_param` on a block inside a library link, Simulink resolves the link if necessary. This operation may involve loading part of the library and executing callbacks.

Break a Link to a Library Block

You can break the link between a linked block and its library block to cause the linked block to become a simple copy of the library block, unlinked to the library block. Changes to the library block no longer affect the block. Breaking links to library blocks may enable you to transport a masked subsystem model as a standalone model, without the libraries (see "Block Masks").

To break the link between a linked block and its library block, you can use any of the following actions.

- Disable the link, then right-click the block and choose **Library Link** > **Break Link** .
- At the command line, change the value of the `LinkStatus` parameter to `'none'` using this command:

  ```
  set_param(gcb, 'LinkStatus', 'none')
  ```
- Right-click and drag to copy a block, and you see an offer to break links, unless the parent library has `LockLinksToLibrary` set to `on`. If your copied block will be a locked link, then you do not see the option to break links.

  To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. Any locked links are ignored and not broken.
- When saving the model, you can break links by supplying arguments to the `save_system` command. See save_system.

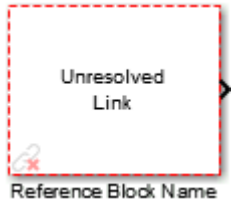
Note Breaking library links in a model does not guarantee that you can run the model standalone, especially if the model includes blocks from third-party libraries or optional Simulink blocksets. It is possible that a library block invokes functions supplied with

the library and hence can run only if the library is installed on the system running the model. Further, breaking a link can cause a model to fail when you install a new version of the library on a system.

For example, suppose a block invokes a function that is supplied with the library. Now suppose that a new version of the library eliminates the function. Running a model with an unlinked copy of the block results in invocation of a now nonexistent function, causing the simulation to fail. To avoid such problems, you should generally avoid breaking links to libraries.

Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path when it attempts to update the linked block, the link becomes unresolved. Simulink changes the appearance of these blocks.



If you double-click the unresolved block, the parameter dialog box displays an error similar to the following:

```
Failed to find 'source-block-name'
in library 'source-library-name'
referenced by
"linked-block-path".
```

To fix an unresolved link, you must do one of the following:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation** > **Update Diagram** or **Diagram** > **Refresh Blocks**.
- Double-click the unresolved block to open its dialog box (see the `Unresolved Link` block reference page). On the dialog box that appears, correct the path name in the **Source block** field and click **OK**.

Make Backward-Compatible Changes to Libraries

Simulink provides the these features to help you edit the library blocks without invalidating models that use the library blocks.

Forwarding Tables

You can create forwarding tables for libraries to specify how to update links in models to reflect changes in the parameters. Use the Forwarding Table to map old library blocks to new library blocks. For example, if you rename or move a block in a library, you can use a forwarding table to enable Simulink to update models that link to the block. For the forwarding tables to function and update the links, both the old library and the new library must be available.

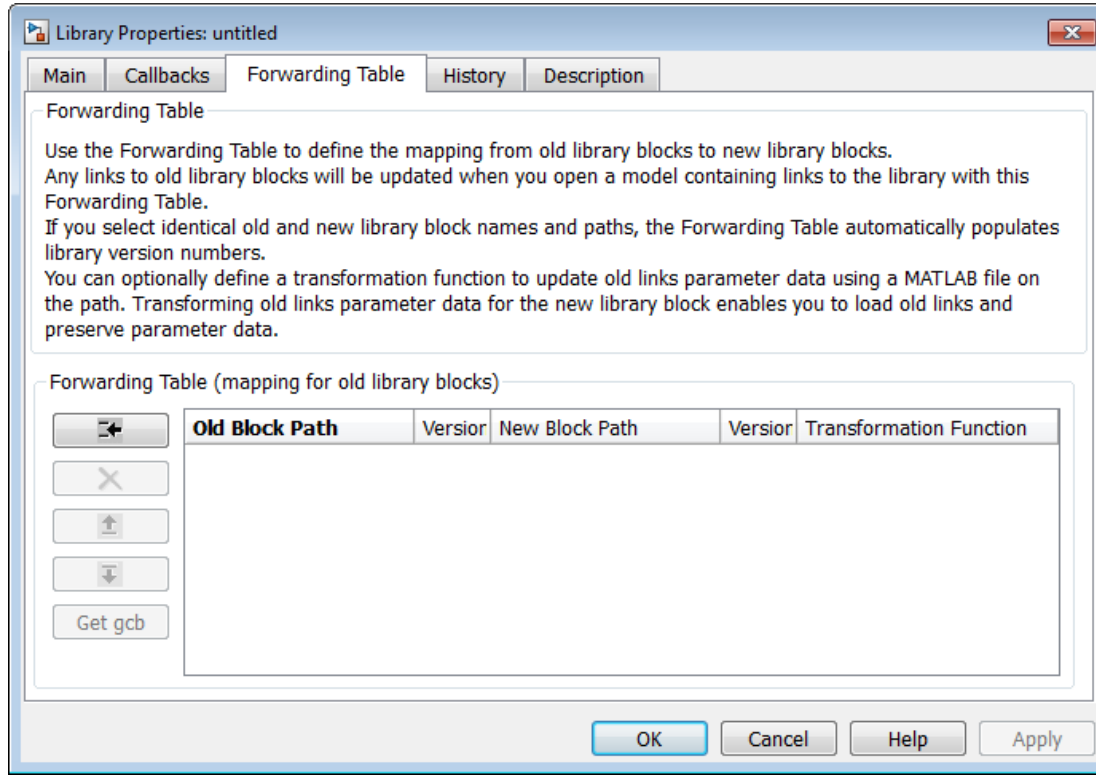
After you specify the forwarding table entry in a library, any links to old library blocks will be updated when you load a model containing links to old blocks. Library authors can use the forwarding tables to automatically transform old links into updated links without any loss of functionality and data. Use the forwarding table to solve compatibility issues with models containing old links that cannot load in the current version of Simulink. Library authors do not need to run the Upgrade Advisor to upgrade old links, and can reduce maintenance of legacy blocks.

To set up a forwarding table for a library,

Note: Models having broken links cannot be updated using forwarding tables. Before you create forwarding table, fix any broken links in the model.

---

1. Unlock the library.
2. Select **File > Library Properties > Library Properties**. The Library Properties dialog box opens.
3. Select the Forwarding Table tab.



4 Define the mapping from old library blocks to new library blocks.

a Click the Add New Entry button. A new row appears in the table.

b Enter values in **Old Block Path** and **New Block Path** columns.

Click **GCB** to get the path of the currently selected block.

If you select identical old and new library block names and paths, the Forwarding Table automatically populates library version numbers in the **Version** columns. The initial value of the `LibraryVersion` property is the `ModelVersion` of the library at the time the link was created. The value updates with increments in the model version of the library.

c (Optional) You can define a transformation function to update old link parameter data using a MATLAB file on the path. Specify the function in the

Transformation Function column. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data.

If you do not want to specify a transformation function, do not edit the field. When you save the library, the column will display `No Transformation`.

5 Click **OK** to apply changes and close the dialog box.

After specifying the forwarding table mapping, when you open a model containing links to the library, links to old library blocks will be updated.

To view an example of a forwarding table:

1 Enter

```
open_system('simulink')
```

2 Select **File > Library Properties > Library Properties**

3 Click the Forwarding Table tab.

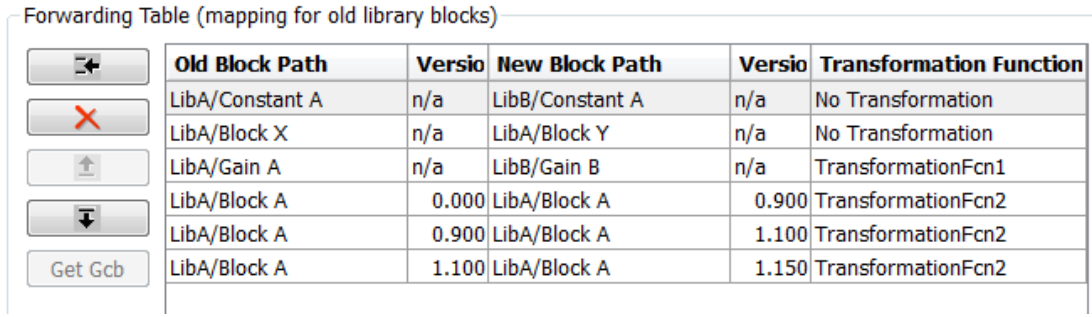
4 View how the forwarding table specifies the mapping of old blocks to new blocks. You cannot make changes because the library is locked. Do not edit the forwarding table for your Simulink library.

5 Click **OK** to close the dialog

The following example shows a forwarding table that defines:

- A block with the same name moving to a different library (`Constant A`)
- A block changing name in the same library (`Block X` to `Block Y`)
- A block changing name, moving library, and applying a transformation function (`Gain A` to `Gain B`)
- A block with three version updates (`Block A`) using a transformation function. When you select identical old and new library block names and paths, the Forwarding Table automatically populates version numbers in the **Version** columns. If this is the first entry with identical names, version starts at `0`, and the new version number is set to the `ModelVersion` of the library. For subsequent entries, the first version

is set to the previous entry's new version, and the new version is set to the current `ModelVersion` of the library.



Old Block Path	Versio	New Block Path	Versio	Transformation Function
LibA/Constant A	n/a	LibB/Constant A	n/a	No Transformation
LibA/Block X	n/a	LibA/Block Y	n/a	No Transformation
LibA/Gain A	n/a	LibB/Gain B	n/a	TransformationFcn1
LibA/Block A	0.000	LibA/Block A	0.900	TransformationFcn2
LibA/Block A	0.900	LibA/Block A	1.100	TransformationFcn2
LibA/Block A	1.100	LibA/Block A	1.150	TransformationFcn2

At the command line you can create a simple forwarding table specifying the old locations and new locations of blocks that have moved within the library or to another library. You associate a forwarding table with a library by setting its `ForwardingTable` parameter to a cell array of two-element cell arrays, each of which specifies the old and new path of a block that has moved. For example, the following command creates a forwarding table and assigns it to a library named Lib1.

```
set_param('Lib1', 'ForwardingTable', {{'Lib1/A', 'Lib2/A'}
{'Lib1/B', 'Lib1/C'}});
```

The forwarding table specifies that block A has moved from Lib1 to Lib2. and that block B is now named C. Suppose that you open a model that contains links to Lib1/A and Lib1/B. Simulink updates the link to Lib1/A to refer to Lib2/A and the link to Lib1/B to refer to Lib1/C. The changes become permanent when you subsequently save the model.

Writing Transformation Functions

You can use transformation functions to add or remove parameters and define parameter values. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data that differs from library values. Define your transformation function using a MATLAB file on the path, then specify the function in the Forwarding Table **Transformation Function** column.

The transformation function in your MATLAB file must be like the following:

```
function outData = TransformationFcn(inData)
```

where `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`, and `ForwardingTableEntry` is a structure.

This general transformation function can have many local functions defined in it. The function calls the appropriate local functions based on old block names and versions. Use this to combine many local functions into a single transformation function, to avoid having many transformation functions on the MATLAB path.

`InstanceData` and `NewInstanceData` are structures with fields `Name` and `Value`. Instance data means the names and values of parameters that are different from the library values.

`outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

The following example code shows how to define a transformation function that adds a parameter with value `uint8` to update a Compare To Constant block:

```
function [outData] = TransformationCompConstBlk(inData)
% Example transformation Function for old 'Compare To Const' block.
%
% If instanceData of old 'Compare To Const' block does not have
% the 'OutDataTypestr' parameter,
% add the parameter with value 'uint8'.
%%

outData.NewBlockPath = '';
outData.NewInstanceData = [];

instanceData = inData.InstanceData;
% Get the field type 'Name' from instanceData
[ParameterNames{1:length(instanceData)}] = instanceData.Name;

if (~ismember('OutDataTypeStr',ParameterNames))
    % OutDataTypeStr parameter is not present in old link. Add it and set value uint8
    instanceData(end+1).Name = 'OutDataTypeStr';
    instanceData(end).Value = 'uint8';
end

outData.NewInstanceData = instanceData;
```

Creating Aliases for Mask Parameters

Simulink lets you create aliases, i.e., alternate names, for a mask's parameters. A model can then refer to the mask parameter by either its name or its alias. This allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models (see “Using Mask Parameter Aliases to Create Backward-Compatible Parameter Name Changes” on page 38-35).

To create aliases for a masked block's mask parameters, use the `set_param` command to set the block's MaskVarAliases parameter to a cell array that specifies the names of the aliases in the same order as the mask names appear in the block's MaskVariables parameter.

Using Mask Parameter Aliases to Create Backward-Compatible Parameter Name Changes

The following example illustrates the use of mask parameter aliases to create backward-compatible parameter name changes.

1. Create a new library. **File** > **New** > **Library**
2. Open the model `masking_example` described in . Drag the masked block named `mx +b` into your new library and rename it to `Line`.
3. Right-click the block and select **Properties**. In the Block Properties dialog, select the **Block Annotation** tab. In the **Enter text and tokens for annotation** box, enter

   ```
   m = %<m>
   b = %<b>
   ```

   The block displays the value of its `m` and `b` parameters,
4. Right-click the block, and select **Mask** > **Mask Parameters**. In the Block Parameters dialog box, type `0.5` for the **Slope** and `0` for the **Intercept**.
5. Save the new library with the filename `mylibrary`.
6. Create a new Simulink model. **File** > **New** > **Model**.
7. From the `mylibrary` window, drag an instance of the Line block to your new model. Rename the instance `LineA`.
8. Right-click the block and select **Mask** > **Mask Parameters**. In the Block Parameters dialog box, change the value **Slope** to `-0.5` and change the value **Intercept** to `30`. Select **Display** > **Library Links** > **User Defined**.
9. Add a Scope and Clock block to your model and connect them to your block. Save the new model with the filename `mymodel`.
10. From the **Simulation** menu, select **Model Configuration Parameters**. From the **Type** list, select `Fixed-step`. From the **Solver** list, select `discrete (no continuous states`. In the **Fixed-step size** box, enter `0.1`. Simulate model.

    Note that the model simulates without error.
11. Save and close `mymodel`.
12. Open `mylibrary`.
13. Edit mask. Right-click block, select **Edit mask**. In the Mask Editor dialog:

    - Select the **Parameters** tab. In the **Dialog parameters** section and **Variable** column, change the variable m to `slope` and `b` to `intercept`.

- Select the Icon & Ports tab. In the Icon Drawing commands box, change the variable `m` to `slope` and `b` to `intercept`.

14 Right-click the Line block, select **Properties**. In the Block Properties dialog,

- Select the **Block Annotation** tab. In the **Enter text and tokens of annotation** box, rename the `m` parameter to `slope` and the `b` parameter to `intercept`.

15 Click **OK** and save `mylibrary`.

16 Reopen `mymodel`.

Note that LineA icon has reverted to the appearance of its library master (i.e., `mylib/Line`) and that its annotation displays question marks for the values of `m` and `b`. These changes reflect the parameter name changes in the library block. In particular, Simulink cannot find any parameters named `m` and `b` in the library block and hence does not know what to do with the instance values for those parameters. As a result, LineA reverts to the default values for the slope and intercept parameters, thereby inadvertently changing the behavior of the model. The following steps show how to use parameter aliases to avoid this inadvertent change of behavior.

17 Close `mymodel`.

18 In the `Library: mylibrary` window, select the Line block.

19 Execute the following command at the MATLAB command line.

```
set_param(gcb, 'MaskVarAliases',{'m', 'b'})
```

This specifies that `m` and `b` are aliases for the Line block `slope` and `intercept` parameters.

20 Reopen `mymodel`.

Note that LineA appearance, not the annotation, now reflects the value of the slope parameter under its original name, i.e., `m`. This is because when Simulink opened the model, it found that `m` is an alias for slope and assigned the value of `m` stored in the model file to the LineA `slope` parameter.

21 Change LineA block annotation property to reflect LineA parameter name changes, replace

```
m = %<m>
b = %<b>
```

with

```
m = %<slope>
b = %<intercept>
```

LineA now appears with m = -0.5 and b = 30.

Note that LineA annotation shows that, thanks to parameter aliasing, Simulink has correctly applied the parameter values stored for LineA in the `mymodel` file to the block renamed parameters.

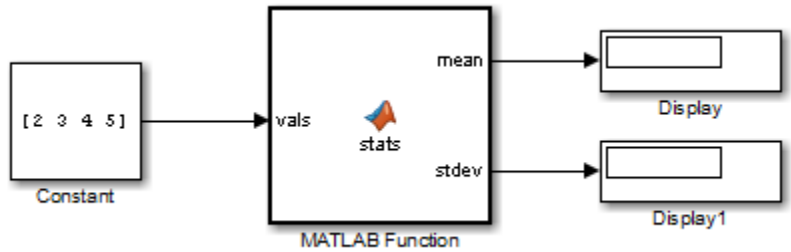
Integrate MATLAB Algorithm in Model

Here is an example of a Simulink model that contains a `MATLAB Function` block:



The `MATLAB Function` block contains the following algorithm:

```
function [mean,stdev] = stats(vals)
% #codegen

% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

You build this model in “Create Model That Uses MATLAB Function Block” on page 39-9.

Defining Local Variables for Code Generation

If you intend to generate code from the MATLAB algorithm in a `MATLAB Function` block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 47-2. In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Generally, once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, but there are exceptions (see “Reassignment of Variable Properties” on page 46-9).

More About

- “What Is a MATLAB Function Block?” on page 39-5

What Is a MATLAB Function Block?

The `MATLAB Function` block allows you to add MATLAB functions to Simulink models for deployment to desktop and embedded processors. This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink. From the `MATLAB Function` block, you can generate readable, efficient, and compact C/C++ code for deployment to desktop and embedded applications.

Calling Functions in MATLAB Function Blocks

`MATLAB Function` blocks can call any of the following types of functions:

- **Local functions**

  Local functions are defined in the body of the `MATLAB Function` block. See "Call Local Functions" on page 55-9.

- **MATLAB toolbox functions that support code generation**

  From `MATLAB Function` blocks, you can call toolbox functions that support code generation. When you build your model with Simulink Coder, these functions generate C code that is optimized to meet the memory and performance requirements of desktop and embedded environments. In the example shown in "Call Local Functions" on page 55-9, `length`, `sqrt`, and `sum` are examples of toolbox functions that support code generation. For a complete list of supported functions, see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2.

- **MATLAB functions that do not support code generation**

  From `MATLAB Function` blocks, you can also call *extrinsic* functions. These are functions on the MATLAB path that the compiler dispatches to MATLAB software for execution because the target language does not support them. These functions do not generate code; they execute only in the MATLAB workspace during simulation of the model. The Simulink Coder software attempts to compile all MATLAB functions unless you explicitly declare them to be extrinsic by using `coder.extrinsic`. See "Declaring MATLAB Functions as Extrinsic Functions" on page 55-12.

  The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out

to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions. This capability removes the requirement to declare these functions extrinsic using the `coder.extrinsic` function.

See "Resolution of Function Calls for Code Generation" on page 55-2.

- **Functions from Simulink Function blocks and Stateflow blocks**

  From `MATLAB Function` blocks, you can also call functions defined in a `Simulink Function` block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

More About

- "Why Use MATLAB Function Blocks?" on page 39-7

Why Use MATLAB Function Blocks?

`MATLAB Function` blocks provide the following capabilities:

- **Allow you to build MATLAB functions into embeddable applications** — `MATLAB Function` blocks support a subset of MATLAB toolbox functions that generate efficient C/C++ code. For information see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2.. With this support, you can use Simulink Coder to generate embeddable C code from `MATLAB Function` blocks that implement a variety of sophisticated mathematical applications. In this way, you can build executables that harness MATLAB functionality, but run outside the MATLAB environment.
- **Inherit properties from Simulink input and output signals** — By default, both the size and type of input and output signals to a `MATLAB Function` block are inherited from Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager (see "Ports and Data Manager" on page 39-34) or in the Model Explorer (see "Model Explorer Overview" on page 12-2).

More About

- "What Is a MATLAB Function Block?" on page 39-5

Use Nondirect Feedthrough in a MATLAB Function Block

By default, `MATLAB Function` blocks have direct feedthrough enabled. To disable, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state.

To use nondirect feedthrough, do not program outputs to rely on inputs or updated persistent variables. For example, do not use the following code in a nondirect feedthrough block:

```
counter = counter + 1;   % update state
output = counter;        % compute output based on updated state
```

Instead, use code such as:

```
output = counter;        % compute output based on current state
counter = counter + 1;   % update state
```

Also, nondirect feedthrough semantics require function inlining. Do not disable inlining.

Using nondirect feedthrough enables you to use `MATLAB Function` blocks in a feedback loop and prevent algebraic loops.

Create Model That Uses MATLAB Function Block

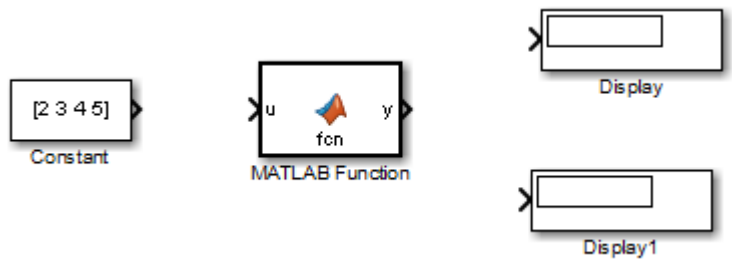
In this section...
“Adding a MATLAB Function Block to a Model” on page 39-9
“Programming the MATLAB Function Block” on page 39-10
“Building the Function and Checking for Errors” on page 39-11
“Defining Inputs and Outputs” on page 39-13

Adding a MATLAB Function Block to a Model

1 Create a new Simulink model and add a `MATLAB Function` block to the model from the User-Defined Functions library:

2 Add the following `Source` and `Sink` blocks to the model:

- From the Sources library, add a `Constant` block to the left of the `MATLAB Function` block and set its value to the vector `[2 3 4 5]`.
- From the Sinks library, add two `Display` blocks to the right of the `MATLAB Function` block.



3 In the Simulink Editor, select **File > Save As** and save the model as `call_stats_block1`.

Programming the MATLAB Function Block

The following exercise demonstrates programming the block to calculate the mean and standard deviation for a vector of values:

1. Open the `call_stats_block1` model that you saved at the end of "Adding a MATLAB Function Block to a Model" on page 39-9. Double-click the `MATLAB Function` block `fcn` to open it for editing.

   A default function signature appears, along with the `%#codegen` directive. In the `MATLAB Function` block, the `%#codegen` directive is included to emphasize that the block's MATLAB algorithm is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the `MATLAB Function` block. For more information see "Compilation Directive %#codegen" on page 55-8.

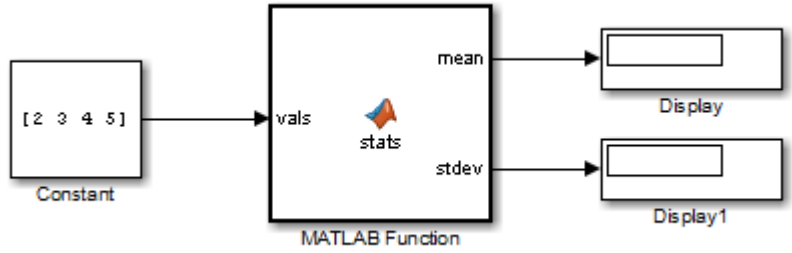
2. Edit the function header line:

   ```
   function [mean,stdev] = stats(vals)
   %#codegen
   ```

   The function `stats` calculates a statistical mean and standard deviation for the values in the vector `vals`. The function header declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

3. Save the model as `call_stats_block2`.

4. Complete the connections to the `MATLAB Function` block as shown.



5. In the `MATLAB Function` Block Editor, enter a line space after the function header and add the following code:

```
% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

More about `length`

The function `length` is an example of a toolbox function that supports code generation. When you simulate this model, C code is generated for this function in the simulation application.

More about `len`

The class, size, and complexity of local variable `len` matches the output of the toolbox function `length`, which returns a real scalar of type `double`.

By default, implicitly declared local variables like `len` are temporary. They come into existence only when the function is called and cease to exist when the function is exited. To make implicitly declared variables persist between function calls, see "Define and Initialize Persistent Variables" on page 46-10.

More about `plot`

The function `plot` is not supported for code generation. The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions.

6 Save the model as `call_stats_block2`.

Building the Function and Checking for Errors

After programming a `MATLAB Function` block in a Simulink model, you can build the function and test for errors. This section describes the steps:

1. Set up your compiler.
2. Build the function.
3. Locate and fix errors.

Setting Up Your Compiler

Building your `MATLAB Function` block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See "Change Default Compiler".

Supported Compilers for Simulation Builds

To view a list of compilers for building models containing `MATLAB Function` blocks for simulation:

1. Navigate to the Supported and Compatible Compilers Web page.
2. Select your platform.
3. In the table for Simulink and related products, find the compilers checked in the column titled Simulink for MATLAB Function blocks.

Supported Compilers for Code Generation

To generate code for models that contain `MATLAB Function` blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

1. Navigate to the Supported and Compatible Compilers Web page.
2. Select your platform.
3. In the table for Simulink and related products, find the compilers checked in the column titled Simulink Coder.

How to Generate Code for the MATLAB Function Block

1. Open the `call_stats_block2` model that you saved at the end of "Programming the MATLAB Function Block" on page 39-10.
2. Double-click its `MATLAB Function` block `stats` to open it for editing.
3. In the MATLAB Function Block Editor, select **Build Model** > **Build** to compile and build the example model.

If no errors occur, the **Simulation Diagnostics** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in "How to Locate and Fix Errors" on page 39-13.

How to Locate and Fix Errors

If errors occur during the build process, the **Simulation Diagnostics** window lists the errors with links to the offending code.

The following exercise shows how to locate and fix an error in a `MATLAB Function` block.

1. In the `stats` function, change the local function `avg` to a fictitious local function `aug` and then compile again to see the following messages in window:

   The **Simulation Diagnostics** window displays each detected error with a red button.

2. Click the first error line to display its diagnostic message in the bottom error window.

   The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see "MATLAB Function Reports" on page 39-46.

3. In the diagnostic message for the selected error, click the blue link after the function name to display the offending code.

   The offending line appears highlighted in the MATLAB Function Block Editor:

4. Correct the error by changing `aug` back to `avg` and recompile.

Defining Inputs and Outputs

In the `stats` function header for the `MATLAB Function` block you defined in "Programming the MATLAB Function Block" on page 39-10, the function argument `vals` is an input, and `mean` and `stdev` are outputs. By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. In this topic, you examine input and output data for the `MATLAB Function` block to verify that it inherits the correct type and size.

1. Open the `call_stats_block2` model that you saved at the end of "Programming the MATLAB Function Block" on page 39-10. Double-click the `MATLAB Function` block `stats` to open it for editing.
2. In the MATLAB Function Block Editor, select **Edit Data**.

   The Ports and Data Manager opens to help you define arguments for `MATLAB Function` blocks.

   The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the `MATLAB Function` block. Notice that `vals` is assigned a **Scope** of `Input`, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope** of `Output`, which is short for **Output to Simulink**.
3. In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

   The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, units, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`, **Complexity** to `Inherited`, and **Type** to `Inherit: Same as Simulink`.

   The actual inherited values for size and type are set during compilation of the model, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

   You can specify the type of an input or output argument by selecting a type in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. See "Type Function Arguments" on page 39-59 and "Size Function Arguments" on page 39-67 for more information on the expressions that you can enter for type and size.

Note: The default first index for any arrays that you add to a `MATLAB Function` block function is `1`, just as it would be in MATLAB.

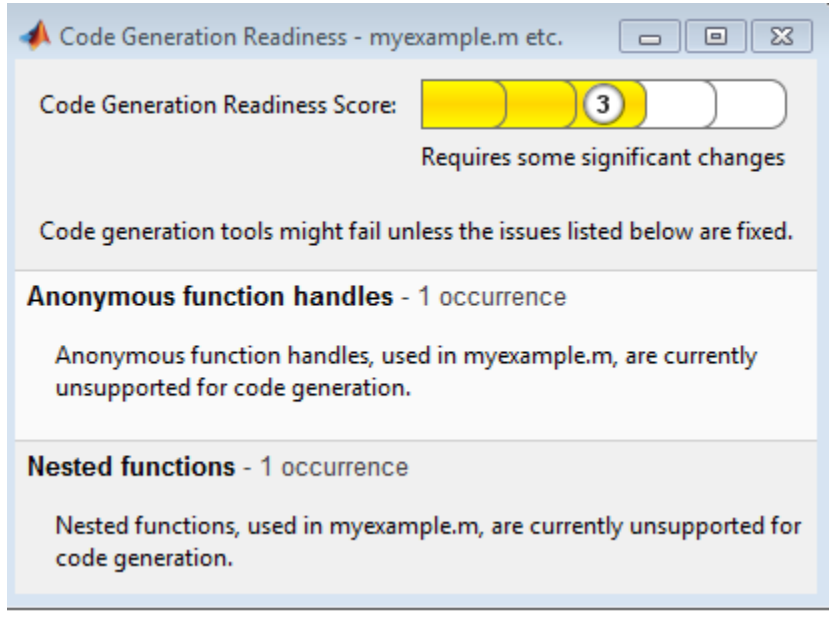
Code Generation Readiness Tool

In this section...
"Information That the Code Generation Readiness Tool Provides" on page 39-16
"Summary Tab" on page 39-16
"Code Structure Tab" on page 39-18

Information That the Code Generation Readiness Tool Provides

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

Summary Tab

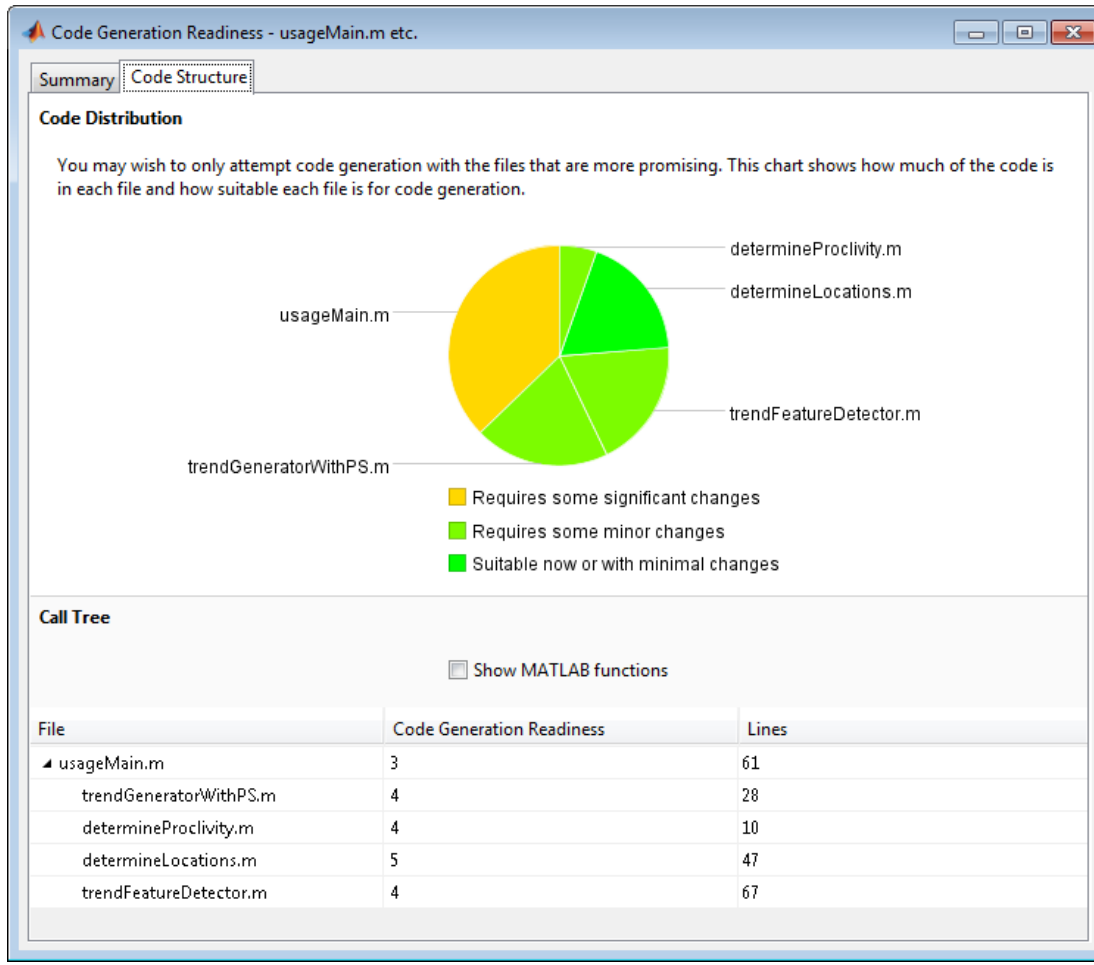


The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features, such as anonymous function handles and nested functions.
- Unsupported data types.

Code Structure Tab



If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

Code Distribution

The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

Call Tree

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from `1` to `5`. A score of `1` indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of `5` indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

Show MATLAB Functions

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to `Yes`.

Check Code Using the Code Generation Readiness Tool

In this section...
"Run Code Generation Readiness Tool at the Command Line" on page 39-22 "Run the Code Generation Readiness Tool From the Current Folder Browser" on page 39-22

Run Code Generation Readiness Tool at the Command Line

1. Navigate to the folder that contains the file that you want to check for code generation readiness.
2. At the MATLAB command prompt, enter:

   ```
   coder.screener('filename')
   ```

   The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

Run the Code Generation Readiness Tool From the Current Folder Browser

1. In the current folder browser, right-click the file that you want to check for code generation readiness.
2. From the context menu, select `Check Code Generation Readiness`.

   The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

More About

- "Code Generation Readiness Tool" on page 39-16

Debugging a MATLAB Function Block

In this section...
"Debugging the Function in Simulation" on page 39-23
"Watching Function Variables During Simulation" on page 39-26
"Checking for Data Range Violations" on page 39-28
"Debugging Tools" on page 39-29

Debugging the Function in Simulation

In "Create Model That Uses MATLAB Function Block" on page 39-9, you created an example model with a `MATLAB Function` block that calculates the mean and standard deviation for a set of input values. The software enables debugging for a `MATLAB Function` when you set a breakpoint.

To debug the `MATLAB Function` in this model:

1. Open the `call_stats_block2` model and double-click the `MATLAB Function` block `stats` to open the editor.
2. In the MATLAB Function Block Editor, click the dash (-) in the left margin of the line:

   ```
   len = length(vals);
   ```

   A red dot appears in the line margin, indicating the breakpoint.

```
function [mean, stdev] = stats(vals)
%#codegen

% Calculates a statistical mean and a standard deviation
% for the values in vals

coder.extrinsic('plot');

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

3 Simulate the model.

Simulation pauses when execution reaches the breakpoint. This is indicated by a green arrow in the margin.

```
function [mean, stdev] = stats(vals)
%#codegen

% Calculates a statistical mean and a standard deviation
% for the values in vals

coder.extrinsic('plot');

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

4 In the toolbar, click **Step** to advance execution.

The execution arrow advances to the next line of `stats`, which calls the local function `avg`.

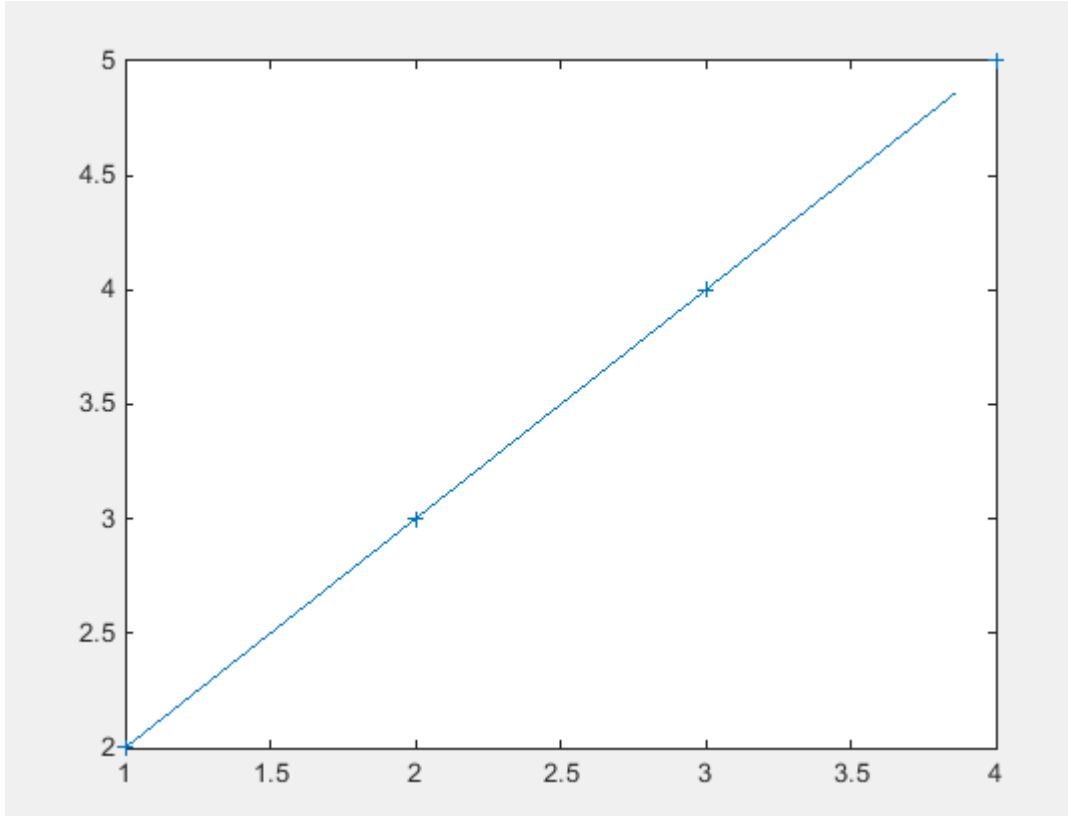
5 In the toolbar, click **Step In**.

Execution advances to enter the local function `avg`. Once you are in a local function, you can use the Step or Step In commands to advance execution. If the local function calls another local function, use Step In to enter it. If you want to execute the remaining lines of the local function, use Step Out.

6. Click **Step** to execute the only line in the local function `avg`. When the local function `avg` finishes executing, a green arrow, pointing down, appears under the last line of the function.
7. Click **Step** to return to the function `stats`.

   Execution advances to the line after the call to the local function `avg`.
8. Click **Step** twice to calculate the `stdev` and to execute the `plot` function.

   The plot function executes in MATLAB:



In the MATLAB Function Block Editor, a green arrow points down under the last line of code, indicating the completion of the function `stats`.

9 Click **Continue** to continue execution of the model.

The computed values of `mean` and `stdev` appear in the `Display` blocks.

10 In the MATLAB Function Block Editor, click **Quit Debugging** to stop simulation.

Watching Function Variables During Simulation

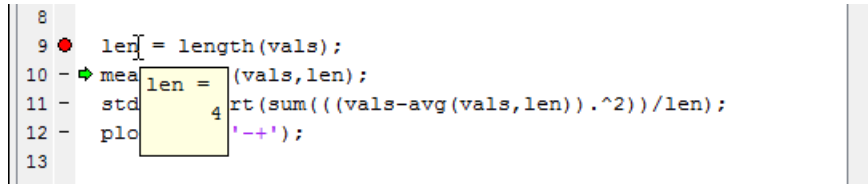
While you simulate a `MATLAB Function` block, you can use several tools to keep track of variable values in the function.

Watching with the Interactive Display

To display the value of a variable in the function of a `MATLAB Function` block during simulation:

1. In the MATLAB Function Block Editor, place the mouse cursor over the variable text and observe the pop-up display.

   For example, to watch the variable `len` during simulation, place the mouse cursor over the text `len` in the code. The value of `len` appears adjacent to the cursor, as shown:



Watching with the Command Line Debugger

You can report the values for a function variable with the Command Line Debugger utility in the MATLAB window during simulation. When you reach a breakpoint, the Command Line Debugger prompt, `debug>>`, appears. At this prompt, you can see the value of a variable defined for the `MATLAB Function` block by entering its name:

```
debug>> stdev

 1.1180

debug>>
```

The Command Line Debugger also provides the following commands during simulation:

Command	Description
`ctrl-c`	Quit debugging and terminate simulation.
`dbcont`	Continue execution to next breakpoint.
`dbquit`	Quit debugging and terminate simulation.
`dbstep [in|out]`	Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.
`help`	Display help for command line debugging.

Command	Description
`print <var>`	Display the value of the variable `var` in the current scope. If `var` is a vector or matrix, you can also index into `var`. For example, `var(1,2)`.
`save`	Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB `save` command. To retrieve variables to the MATLAB base workspace, use `load` command after simulation has been ended.
`<var>`	Equivalent to "print <var>" if variable is in the current scope.
`who`	Display the variables in the current scope.
`whos`	Display the size and class (type) of all variables in the current scope.

You can issue any other MATLAB command at the `debug>>` prompt, but the results are executed in the workspace of the `MATLAB Function` block. To issue a command in the MATLAB base workspace at the `debug>>` prompt, use the `evalin` command with the first argument `'base'` followed by the second argument command string, for example, `evalin('base','whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

Watching with MATLAB

You can display the execution result of a `MATLAB Function` block line by omitting the terminating semicolon. If you do, execution results for the line are echoed to the MATLAB window during simulation.

Display Size Limits

The MATLAB Function Block Editor does not display the contents of matrices that have more than two dimensions or more than `200` elements. For matrices that exceed these limits, the MATLAB Function Block Editor displays the shape and base type only.

Checking for Data Range Violations

`MATLAB Function` blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, set **Simulation range checking** in the **Diagnostics: Data Validity** pane of the Configuration Parameters dialog box to `error`.

Specifying a Range

To specify a range for input and output data, follow these steps:

1 In the Ports and Data Manager, select the input or output of interest.

   The data properties dialog box opens.

2 In the data properties dialog box, select the General tab and enter a limit range, as described in "Setting General Properties" on page 39-39.

Debugging Tools

Use the following tools during a `MATLAB Function` block debugging session:

Tool Button	Description	Shortcut Key
Build	Access this tool from the **Editor** tab by selecting **Build Model > Build**. Check for errors and build a simulation application (if no errors are found) for the model containing this `MATLAB Function` block.	**Ctrl+B**
Update Diagram	Access this tool from the **Editor** tab by selecting **Build Model > Update Diagram**. Check for errors based on the latest changes you make to the `MATLAB Function` block.	**Ctrl+D**
Update Ports	Access this tool from the **Editor** tab by selecting **Build Model > Update Ports**. Updates the ports of the `MATLAB Function` block with the latest changes made to the function argument and return values without closing the MATLAB Function Block Editor.	**Ctrl+Shift+A**
Run Model	Start simulation of the model containing the `MATLAB Function` block. If execution is paused at a breakpoint, continues debugging.	**F5**
Stop Model	Stop simulation of the model containing the `MATLAB Function` block. Alternatively, from the **Editor** tab, select **Quit Debugging** if execution is paused at a breakpoint.	**Shift+F5**

Tool Button	Description	Shortcut Key
Set/Clear	Access this tool by selecting **Breakpoints > Set/ Clear**. Set a new breakpoint or clear an existing breakpoint for the selected line of code in the `MATLAB Function` block. The presence of the text cursor or highlighted text selects the line. A breakpoint indicator appears in the on the selected line. Alternatively, click the hyphen character (-) next to the line number. A breakpoint indicator appears in place of the hyphen. Click the breakpoint indicator to clear the breakpoint.	**F12**
Clear All	Access this tool by selecting **Breakpoints > Clear All**. Clear all existing breakpoints in the `MATLAB Function` block code.	**None**
Step	Step through the execution of the next line of code in the `MATLAB Function` block. This tool steps past function calls and does not enter called functions for line-by-line execution. You can use this tool only after execution has stopped at a breakpoint.	**F10**
Step In	Step through the execution of the next line of code in the `MATLAB Function` block. If the line calls a local function, step into the first line of the local function. You can use this tool only after execution has stopped at a breakpoint.	**F11**
Step Out	Step out of line-by-line execution of the current function or local function. If in a local function, the debugger continues to the line following the call to this local function. You can use this tool only after execution has stopped at a breakpoint.	**Shift+F11**

Tool Button	Description	Shortcut Key
Continue	Continue debugging after a pause, such as stopping at a breakpoint. You can use this tool only after execution has stopped at a breakpoint.	**F5**
Quit Debugging	Exit debug mode. You can use this tool only after execution has stopped at a breakpoint.	**Shift+F5**

More About

- “What Is a MATLAB Function Block?” on page 39-5

- “MATLAB Function Reports” on page 39-46

MATLAB Function Block Editor

In this section...
“Customizing the MATLAB Function Block Editor” on page 39-32
“MATLAB Function Block Editor Tools” on page 39-32
“Editing and Debugging MATLAB Function Block Code” on page 39-33
“Ports and Data Manager” on page 39-34

Customizing the MATLAB Function Block Editor

Use the toolbar icons to customize the appearance of the MATLAB Function Block Editor in the same manner as the MATLAB editor. See “Basic Settings”.

MATLAB Function Block Editor Tools

Use the following tools to work with the `MATLAB Function` block:

Tool Button	Description
Edit Data	Opens the Ports and Data Manager dialog to add or modify arguments for the current `MATLAB Function` block (see “Ports and Data Manager” on page 39-34).
View Report	Opens the MATLAB Function report for the `MATLAB Function` block. For more information, see “MATLAB Function Reports” on page 39-46.
Simulation Target	Opens the **Simulation Target** pane in the **Configuration Parameters** dialog to include custom code.
Go To Diagram	Displays the MATLAB function in its native diagram without closing the editor.

See “Defining Inputs and Outputs” on page 39-13 for an example of defining an input argument for a `MATLAB Function` block.

Editing and Debugging MATLAB Function Block Code

Manual Indenting

To indent a block of code manually:

1. Highlight the text that you would like to indent.
2. Select one of the Indent tools on the Editor tab:

Tool	Description
	Applies smart indenting to selected text.
	Move selected text right one indent level.
	Move selected text left one indent level.

Opening a Selection

You can open a local function, function, file, or variable from within a file in the MATLAB Function Block Editor.

To open a selection:

1. Position the cursor in the name of the item you would like to open.
2. Right-click and select **Open <selection>** from the context menu.

The Editor chooses the appropriate tool to open the selection. For more information, refer to “Manage Files and Folders”.

Note: If you open a `MATLAB Function` block input or output parameter, the Ports and Data Manager opens with the selected parameter highlighted. You can use the Ports and Data Manager to modify parameter attributes. For more information, refer to “Ports and Data Manager” on page 39-34.

Evaluating a Selection

You can use the **Evaluate a Selection** menu option to report the value for a MATLAB function variable or equation in the MATLAB window during simulation.

To evaluate a selection:

1. Highlight the variable or equation that you would like to evaluate.
2. Hold the mouse over the highlighted text and then right-click and select **Evaluate Selection** from the context menu. (Alternatively, select **Evaluate Selection** from the **Text** menu).

When you reach a breakpoint, the MATLAB command Window displays the value of the variable or equation at the Command Line Debugger prompt.

```
debug>> stdev

 1.1180

debug>>
```

Note: You cannot evaluate a selection while MATLAB is busy, for example, running a MATLAB file.

Setting Data Scope

To set the data scope of a `MATLAB Function` block input parameter:

1. Highlight the input parameter that you would like to modify.
2. Hold the mouse over the highlighted text and then right-click and select **Data Scope for <selection>** from the context menu.
3. Select:
   - **Input** if your input data is provided by the Simulink model via an input port to the `MATLAB Function` block.
   - **Parameter** if your input is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block.

For more information, refer to "Setting General Properties" on page 39-39.

Ports and Data Manager

The Ports and Data Manager provides a convenient method for defining objects and modifying their properties in a `MATLAB Function` block.

The Ports and Data Manager provides the same data definition capabilities for individual `MATLAB Function` blocks as the Model Explorer provides across the model hierarchy (see “Model Explorer Overview” on page 12-2).

Ports and Data Manager Dialog Box

The Ports and Data Manager dialog box allows you to add and define data arguments, input triggers, and function call outputs for `MATLAB Function` blocks. Using this dialog, you can also modify properties for the `MATLAB Function` block and the objects it contains.

The dialog box consists of two panes:

- The **Contents** (left) pane lists the objects that have been defined for the `MATLAB Function` block.
- The **Dialog** (right) pane displays fields for modifying the properties of the selected object.

Properties vary according to the scope and type of the object. Therefore, the Ports and Data Manager properties dialogs are dynamic, displaying only the property fields that are relevant for the object you add or modify.

When you first open the dialog box, it displays the properties of the `MATLAB Function` block.

Opening the Ports and Data Manager

To open the Ports and Data Manager from the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the `MATLAB Function` block that is open and has focus.

Ports and Data Manager Tools

The following tools are specific to the Ports and Data Manager:

Tool Button	Description
Go to Block Editor	Displays the MATLAB function in the MATLAB Function Block Editor.
	Displays the default MATLAB function properties (see “MATLAB Function Block Properties” on page 39-36). Use

Tool Button	Description
Show Block Dialog	this button to return to the settings used by the block after viewing data associated with the block arguments.

MATLAB Function Block Properties

This section describes each property of a `MATLAB Function` block.

Name

Name of the `MATLAB Function` block, following the same naming conventions as for Simulink blocks (see "Manipulate Block Names" on page 33-15).

Update method

Method for activating the `MATLAB Function` block. You can choose from the following update methods:

Update Method	Description
Inherited (default)	Input from the Simulink model activates the `MATLAB Function` block. If you define an input trigger, the `MATLAB Function` block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the `MATLAB Function` block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the chart. If you define data inputs, the `MATLAB Function` block samples at the rate of the fastest data input. If you do not define data inputs, the `MATLAB Function` block samples as defined by its parent subsystem's execution behavior.
Discrete	The `MATLAB Function` block is sampled at the rate you specify as the block's **Sample Time** property. An implicit event is generated at regular time intervals corresponding to the specified rate. The sample time is in the same units as the Simulink simulation time. Note that other blocks in the model can have different sample times.
Continuous	The Simulink software wakes up (samples) the `MATLAB Function` block at each step in the simulation, as well as at intermediate time points that can be requested by the solver. This method is consistent with the continuous method.

Saturate on integer overflow

Option that determines how the `MATLAB Function` block handles overflow conditions during integer operations:

Setting	Action When Overflow Occurs
Enabled (default)	Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. Matches MATLAB behavior.
Disabled	In simulation mode, generates a run-time error. For Simulink Coder code generation, the behavior depends on your C language compiler.

Note: The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow will not occur in your `MATLAB Function` block code.

Note that the code generated by Simulink Coder does *not* check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, it is recommended that you simulate first to test for overflow and underflow before generating code.

Lock Editor

Option for locking the MATLAB Function Block Editor. When enabled, this option prevents users from making changes to the `MATLAB Function` block.

Treat these inherited Simulink signal types as fi objects

Setting that determines whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects (“Ways to Construct fi Objects”).

- When you select `Fixed-point`, the `MATLAB Function` block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.
- When you select `Fixed-point & Integer`, the `MATLAB Function` block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

MATLAB Function block fimath

Setting that defines `fimath` properties for the `MATLAB Function` block. The block associates the `fimath` properties you specify with the following objects:

- All fixed-point and integer input signals to the `MATLAB Function` block that you choose to treat as `fi` objects.
- All `fi` and `fimath` objects constructed in the `MATLAB Function` block.

You can select one of the following options for the **MATLAB Function block fimath**.

Setting	Description
Same as MATLAB	When you select this option, the block uses the same `fimath` properties as the current default fimath. The edit box appears dimmed and displays the current global fimath in read-only form.
Specify other	When you select this option, you can specify your own `fimath` object in the edit box. You can do so in one of two ways: • Constructing the `fimath` object inside the edit box. • Constructing the `fimath` object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, make sure you define the variable in the model workspace. See "Sharing Models with Fixed-Point MATLAB Function Blocks". For more information on `fimath` objects, see "fimath Object Construction".

Description

Description of the `MATLAB Function` block.

Document link

Link to documentation for the `MATLAB Function` block. To document a `MATLAB Function` block, set the **Document link** property to a Web URL address or MATLAB expression that displays documentation in a suitable format (for example, an HTML file or text in the MATLAB Command Window). The `MATLAB Function` block evaluates the expression when you click the blue **Document link** text.

Adding Data to a MATLAB Function Block

You can define data arguments for `MATLAB Function` blocks using the following methods:

Method	For Defining	Reference
Define data directly in the `MATLAB Function` block code	Input and output data	See "Defining Inputs and Outputs" on page 39-13.
Use the Ports and Data Manager	Input, output, and parameter data in the `MATLAB Function` block that is open and has focus	See "Defining Data in the Ports and Data Manager" on page 39-39.
Use the Model Explorer	Input, output, and parameter data in `MATLAB Function` blocks at all levels of the model hierarchy	See "Model Explorer Overview" on page 12-2

Defining Data in the Ports and Data Manager

To add a data argument, in the Ports and Data Manager, select **Add** > **Data** and modify the data properties.

Setting General Properties

You can set the following properties in the General tab:

Property	Description
Name	Name of the data argument, following the same naming conventions used in MATLAB.
Scope	Where data resides in memory, relative to its parent. Scope determines the range of functionality of the data argument. You can set scope to one of the following values: • `Parameter`— Specifies that the source for this data is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the variable closest to the block in the workspace hierarchy is used (see "Model Workspaces" on page 4-86). • `Input`— Data provided by the model via an input port to the `MATLAB Function` block.

Property	Description
	• `Output`— Data provided by the `MATLAB Function` block via an output port to the model. • `Data Store Memory`— Data provided by a `Data Store Memory` block in the model. For more information, see "Defining Inputs and Outputs" on page 39-13 and "Add Parameter Arguments" on page 39-71.
Port	Index of the port associated with the data argument. This property applies only to input and output data.
Tunable	Indicates whether the parameter used as the source of this data item is tunable (see "Tunable Parameters" on page 3-8). This property applies only to parameter data. Clear this option if the parameter must be a constant expression, such as for MATLAB toolbox functions supported for code generation (see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2).
Data must resolve to Simulink signal object	Specifies that the data argument must resolve to a Simulink signal object. This property applies only to output data. See "Symbol Resolution" on page 4-97 for more information.
Size	Size of the data argument. Size can be a scalar value or a MATLAB vector of values. Size defaults to –1, which means that it is inherited, as described in "Inheriting Argument Sizes from Simulink" on page 39-67. This property does not apply to Data Store Memory data. For more details, see "Size Function Arguments" on page 39-67.
Variable Size	Indicates whether the size of this data item is variable. This property does not apply to Data Store Memory data.
Complexity	Indicates real or complex data arguments. You can set complexity to one of the following values: • `Off`— Data argument is a real number • `On`— Data argument is a complex number • `Inherited`— Data argument inherits complexity based on its scope. Input and output data inherit complexity from the Simulink signals connected to them; parameter data inherits complexity from the parameter to which it is bound.

Property	Description
Type	Type of data object. You can specify the data type by: • Selecting a built-in type from the **Type** drop down list. • Entering an expression in the **Type** field that evaluates to a data type (see "About Data Types in Simulink" on page 57-2). • Using the Data Type Assistant to specify a data **Mode**, then specifying the data type based on that mode. **Note:** To display the Data Type Assistant, click the Show data type assistant button: For more information, see "Specifying Argument Types" on page 39-59.
Unit (e.g., m, m/s^2, N*m)	Specify physical units for input and output data. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See "Units in MATLAB Function Blocks" on page 39-70.
Limit range	Specify the range of acceptable values for input or output data. The `MATLAB Function` block uses this range to validate the input or output as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar value. • **Minimum** — The smallest value allowed for the data item during simulation. The default value is `-inf`. • **Maximum** — The largest value allowed for the data item during simulation. The default value is `inf`.

Setting Description Properties

You can set the following properties on the Description tab:

Property	Description
Save final value to base workspace	The `MATLAB Function` block assigns the value of the data argument to a variable of the same name in the MATLAB base workspace at the end of simulation.

Property	Description
Description	Description of the data argument.
Document link	Link to documentation for the data argument. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text, **Document link**, displayed at the bottom of the **Data** properties dialog, the `MATLAB Function` block evaluates the link and displays the documentation.

Adding Input Triggers to a MATLAB Function Block

An input trigger is an event on the input port that causes the `MATLAB Function` block to execute. See "Create a Triggered Subsystem" on page 10-38.

You can define the following types of triggers in `MATLAB Function` blocks:

- Rising
- Falling
- Either (rising or falling)
- Function call

For a description of each trigger type, see "Setting Input Trigger Properties" on page 39-43.

Use the Ports and Data Manager to add input triggers to a `MATLAB Function` block that is open and has focus. To add an input trigger and modify its properties, follow these steps:

1. In the Ports and Data Manager, select **Add** > **Input Trigger**.

   The Ports and Data Manager adds a default definition of the new input trigger to the `MATLAB Function` block and displays the Trigger properties dialog.
2. Modify trigger properties.
3. Return to the `MATLAB Function` block properties at any time by selecting **Tools** > **Block Dialog**.

The Trigger Properties Dialog

The Trigger properties dialog in the Ports and Data Manager allows you to set and modify the properties of input triggers in `MATLAB Function` blocks.

To open the Trigger properties dialog, select an input trigger in the Contents pane.

Setting Input Trigger Properties

You can set the following properties in the Trigger properties dialog:

Property	Description
Name	Name of the input trigger, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the input trigger. The default value is `1`.
Trigger	Type of event that triggers execution of the `MATLAB Function` block. You can select one of the following types of triggers: • `Rising` (default) — Triggers execution of the `MATLAB Function` block when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative). • `Falling`— Triggers execution of the `MATLAB Function` block when the control signal falls from a positive or zero value to a negative value (or zero if the initial value is positive). • `Either`— Triggers execution of the `MATLAB Function` block when the control signal is either rising or falling. • `Function call`— Triggers execution of the `MATLAB Function` block from a block that outputs function-call events, or from an S-function
Description	Description of the input trigger.
Document link	Link to documentation for the input trigger. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text that reads **Document link** displayed at the bottom of the **Trigger** properties dialog, the `MATLAB Function` block evaluates the link and displays the documentation.

Adding Function Call Outputs to a MATLAB Function Block

A function call output is an event on the output port of a `MATLAB Function` block that causes a `Function-Call Subsystem` block in the Simulink model to execute. Another

block can invoke a function-call subsystem directly during a simulation. See “Create a Function-Call Subsystem” on page 10-52.

Use the Ports and Data Manager to add and modify function call outputs to a `MATLAB Function` block that is open and has focus. To add a function call output and modify its properties, follow these steps:

1. In the Ports and Data Manager, select **Add** > **Function Call Output**.

   The Ports and Data Manager adds a default definition of the new function call output to the `MATLAB Function` block and displays the Function Call properties dialog.
2. Modify function call output properties.
3. Return to the `MATLAB Function` block properties at any time by selecting **Tools** > **Block Dialog**.

Considerations when Supplying Output to the Function-Call Subsystem

If a `MATLAB Function` block triggers a function-call subsystem, and supplies an output signal to the same function-call subsystem, the signal to the function-call subsystem can effectively be delayed by one time step compared to the function call. At the moment of the function call, the function-call subsystem sees the previous `MATLAB Function` block outport value even if the output data has been updated within the block MATLAB code.

The Function Call Properties Dialog

The Function Call properties dialog in the Ports and Data Manager allows you to edit the properties of function call outputs in `MATLAB Function` blocks.

To open the Function Call properties dialog, select a function call output in the Contents pane.

Setting Function Call Output Properties

You can set the following properties in the Function Call properties dialog:

Property	Description
Name	Name of the function call output, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the function call output. Function call output ports are numbered sequentially after input and output ports.

Property	Description
Description	Description of the function call output.
Document link	Link to documentation for the function call output. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click **Document link** displayed at the bottom of the **Function Call** properties dialog, the `MATLAB Function` block evaluates the link and displays the documentation.

About MATLAB Function Reports

When you build a Simulink model that contains `MATLAB Function` blocks, Simulink generates a report in HTML format for each `MATLAB Function` block in your model. You can use the report to debug your MATLAB functions and verify that they are suitable for code generation. The report provides links to your MATLAB functions and compile-time type information for the variables and expressions in these functions. If your model fails to build, this information simplifies finding sources of error messages and aids understanding of type propagation rules.

Note: If you have a Stateflow license, there is one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

Note: If you have identical `MATLAB Function` blocks in your model, for example, one in a library and one in the model, a single report is generated for the identical blocks.

Opening MATLAB Function Reports

Use one of the following methods:

- In the MATLAB Function Block Editor, select **View Report**.
- If compilation errors occur, in the **Diagnostic Viewer** window, select the`report` link.

Description of MATLAB Function Reports

When you build the MATLAB function, the code generation software generates an HTML report. The report provides the following information, as applicable:

- MATLAB code information, including a list of all functions and their compilation status
- Call stack information, providing information on the nesting of function calls
- Summary of compilation results, including type of target and number of warnings or errors
- List of error and warning messages
- List of variables in your MATLAB function

Viewing Your MATLAB Function Code

To view your MATLAB function code, click the **MATLAB code** tab. The report displays the MATLAB code for the function highlighted in the list on this tab.

The **MATLAB code** tab provides:

- A list of the MATLAB functions that have been compiled. The report displays icons next to each function name to indicate whether compilation was successful:
  - Errors in function.
  - Warnings in function.
  - Successful compilation, no errors or warnings.
- A filter control that you can use to sort your functions by:

- Size
- Complexity
- Class

Viewing Local Functions

The report annotates the local function with the name of the parent function in the list of functions on the **MATLAB code** tab.

For example, if the MATLAB function `fcn1` contains the local function `subfcn` and `fcn2` contains the local function `subfcn2`, the report displays:

```
fcn1 > subfcn1
fcn2 > subfcn2
```

Viewing Specializations

If your MATLAB function calls the same function with different types of inputs, the report numbers each of these **specializations** in the list of functions on the **MATLAB code** tab.

For example, if the function `fcn` calls the function `subfcn` with different types of inputs:

```
function y = fcn(u) %#codegen
% Specializations
y = y + subfcn(single(u));
y = y + subfcn(double(u));
```

The report numbers the specializations in the list of functions.

```
fcn > subfcn > 1
fcn > subfcn > 2
```

Viewing Call Stack Information

The report provides call stack information:

- On the **Call stack** tab.
- In the list of **Callers**.

  If a function is called from more than one function, this list provides details of each call site. Otherwise, the list is disabled.

Viewing Call Stack Information on the Call Stack Tab

To view call stack information, click the **Call stack** tab. The call stack lists the functions in the order that the top-level function calls them. It also lists the local functions that each function calls.

Viewing Function Call Sites in the Callers List

If a function is called from more than one function, this list provides details of each call site. To navigate between call sites, select a call site from the **Callers** list. If the function is not called more than once, this list is disabled.

Viewing the Compilation Summary Information

To view a summary of the compilation results, including type of target and number of errors or warnings, click the **Summary** tab.

Viewing Error and Warning Messages

The report provides information about errors and warnings. If errors occur during simulation of a Simulink model, simulation stops. If warnings occur, but no errors, simulation of the model continues.

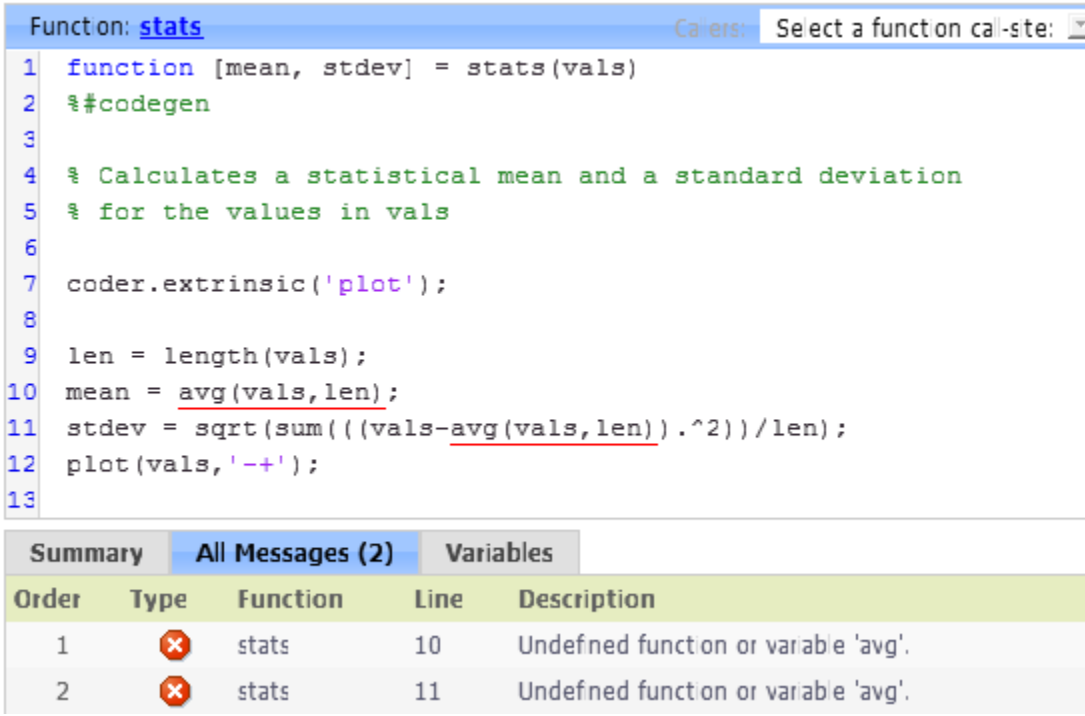
The report provides information about warnings and errors by listing all errors and warnings in chronological order in the **All Messages** tab.

Viewing Errors and Warnings in the All Messages Tab

If errors or warnings occurred during compilation, click the **All Messages** tab to view a complete list of these messages. The report lists the messages in the order that the compiler detects them. It is best practice to address the first message in the list, because often subsequent errors and warnings are related to the first message.

To locate the offending line of code for an error or warning in the list, click the message in the list. The report highlights errors in the list and MATLAB code in red and warnings in orange. Click the blue line number next to the offending line of code in the MATLAB code pane to go to the error in the source file.

Note: You can fix errors only in the source file.



Viewing Error and Warning Information in Your MATLAB Code

If errors or warnings occurred during compilation, the report underlines them in your MATLAB code. The report underlines errors in red and warnings in orange. To learn more about a particular error or warning, place your pointer over the underlined text.

MATLAB Code Variables in a Report

The report provides compile-time type information for the variables and expressions in your MATLAB code, including name, type, size, complexity, and class. It also provides type information for fixed-point data types, including word length and fraction length. You can use this type information to find the sources of error messages and to understand type propagation rules.

You can view information about the variables in your MATLAB code:

- On the **Variables** tab, view the list.

- In your MATLAB code, place your cursor over the variable name.

  In the MATLAB code, an orange variable name indicates a compile-time constant argument to a specialized function. The information for a constant argument includes the value. This information helps you to see when code generation created function specializations for different constant argument values.

Variables on the Variables Tab

To view a list of the variables in your MATLAB function, click the **Variables** tab. The report displays a complete list of variables in the order that they appear in the function that you selected on the **MATLAB code** tab. Clicking a variable in the list highlights instances of that variable, and scrolls the MATLAB code pane so that you can view the first instance.

As applicable, the report provides the following information about each variable:

- Order
- Name
- Type
- Size
- Complexity
- Class
- DataTypeMode (DT mode) — for fixed-point data types only. For more information, see "Data Type and Scaling Properties".
- Signed — sign information for built-in data types, signedness information for fixed-point data types.
- Word length (WL) — for fixed-point data types only.
- Fraction length (FL) — for fixed-point data types only.

Note: For more information on viewing fixed-point data types, see "Use Fixed-Point Code Generation Reports".

The report displays a column only if at least one variable in the code has information in that column. For example, if the code does not contain fixed-point data types, the report does not display the `DT mode`, `WL`, or `FL` columns.

Sorting Variables on the Variables Tab

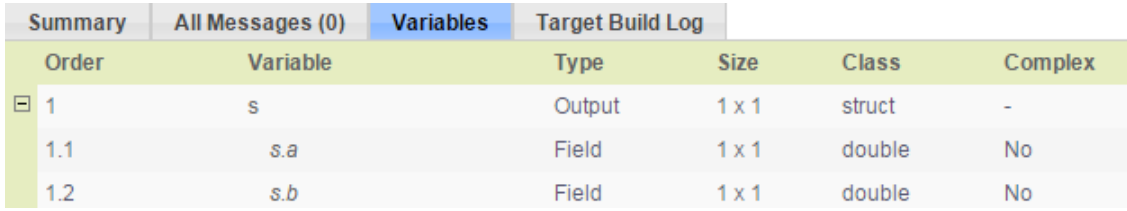
By default, the report lists the variables in the order that they appear in the selected function.

To sort the variables, click the column headings on the **Variables** tab. To sort the variables by multiple columns, hold down the **Shift** key when you click the column headings.

To restore the list to the original order, click the **Order** column heading.

Structures on the Variables Tab

To display structure field properties, expand the structure on the **Variables** tab.

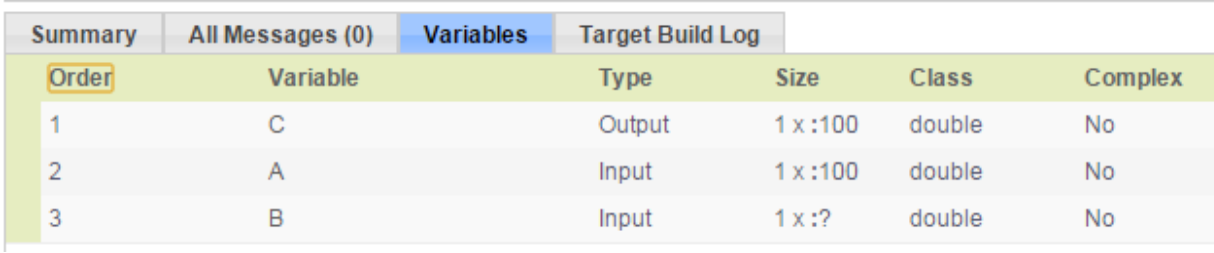


If you sort the variables by type, size, complexity, or class, it is possible that a structure and its fields do not appear sequentially in the list. To restore the list to the original order, click the **Order** column heading.

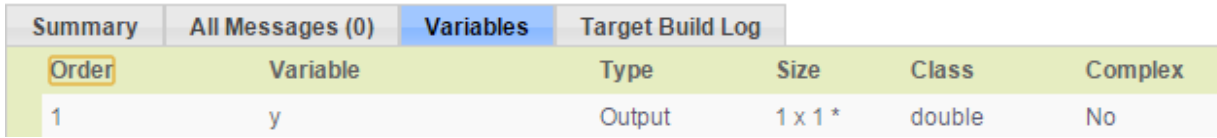
Variable-Size Arrays in the Variables Tab

For variable-size arrays, the **Size** field includes information about the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon `:`. The size of an unbounded dimension is `:?`.

In the following report, variables `A` and `B` are variable-size. The second dimension of `A` has a maximum size of 100. The size of the second dimension of `B` is `:?`.



If you declare a variable-size array, and then fix the dimensions of this array in the code, the report appends `*` to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the sizes of its dimensions do not change during execution.

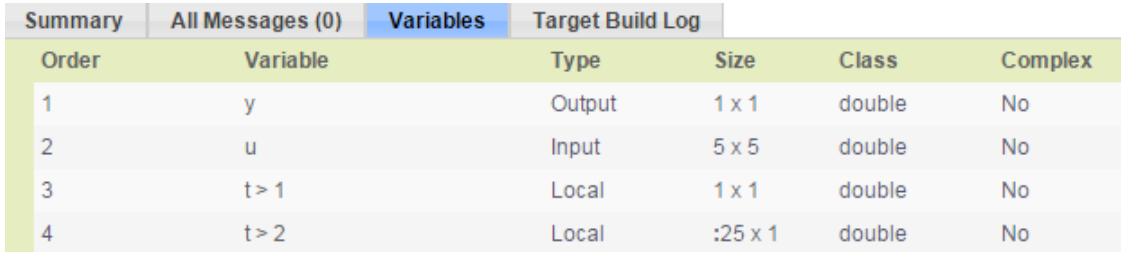


For information about how to use the size information for variable-size arrays, see "Variable-Size Data Definition for Code Generation".

Renamed Variables in the Variables Tab

If your MATLAB function reuses a variable with a different size, type, or complexity, the code generation software attempts to create separate, uniquely named variables. For more information, see "Reuse the Same Variable with Different Properties". The report numbers the renamed variables in the list on the **Variables** tab. When you place your cursor over a renamed variable, the report highlights only the instances of this variable that share data type, size, and complexity.

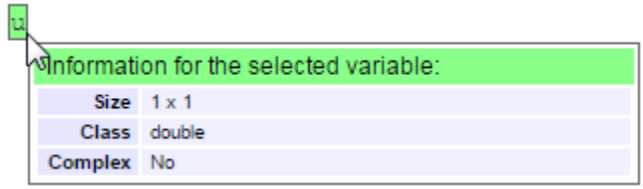
For example, suppose that your code uses the variable `t` to hold a scalar double, and reuses it outside the for-loop to hold a vector of doubles. In the list on the **Variables** tab, the report displays two variables, `t>1` and `t>2`,



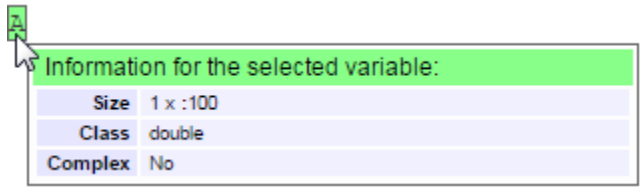
Viewing Information About Variables and Expressions in Your MATLAB Function Code

To view information about a particular variable or expression in your MATLAB function code, on the MATLAB code pane, place your cursor over the variable name or expression. The report highlights variables and expressions in different colors:

Green, when the variable has data type information at this location in the code



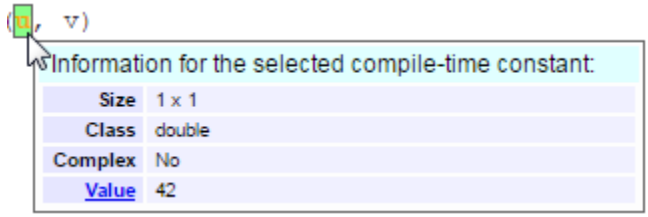
For variable-size arrays, the **Size** field includes information on the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon `:`.



Green with orange text, when a constant argument has data type and value information

When the variable is a compile-time constant argument to a specialized function:

- The variable name is orange.
- The information for the variable includes the value.



If you export the value as a variable to the base workspace, you can use the Workspace browser to view detailed information about the variable.

To export the value to the base workspace:

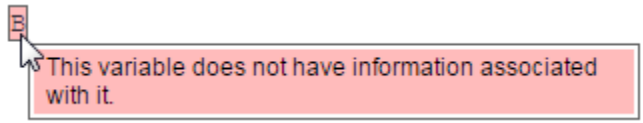
1. Click the **Value** link.

2 In the Export Constant Value dialog box, specify the **Variable name**.

3 Click **OK**.

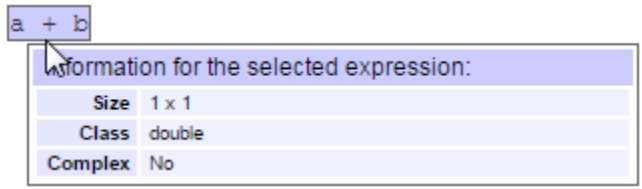
The variable and its value appear in the Workspace browser.

Pink, when the variable has no data type information

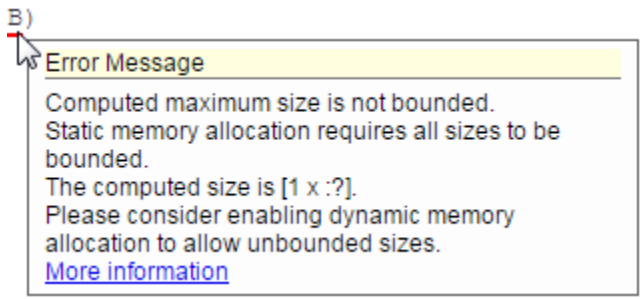


Purple, information about expressions

You can also view information about expressions in your MATLAB code. On the MATLAB code pane, place your cursor over an expression. The report highlights expressions in purple and provides more detailed information.



Red, when there is error information



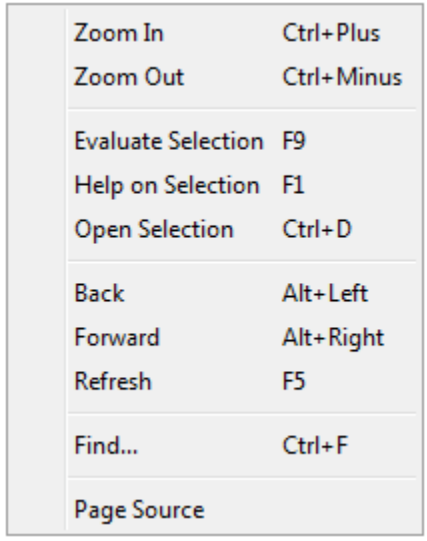
Keyboard Shortcuts for the MATLAB Function Report

You can use keyboard shortcuts settings to perform actions in the report.

This table lists actions that you can associate with a keyboard shortcut. The keyboard shortcuts are defined in your MATLAB preferences. See “Define Keyboard Shortcuts”.

Action	Default Keyboard Shortcut for a Windows Platform
Zoom in	**Ctrl+Plus**
Zoom out	**Ctrl+Minus**
Evaluate selected MATLAB code	**F9**
Open help for selected MATLAB code	**F1**
Open selected MATLAB code	**Ctrl+D**
Step backward through files that you opened in the code pane	**Alt+Left**
Step forward through files that you opened in the code pane	**Alt+Right**
Refresh	**F5**
Search	**Ctrl+F**

Alternatively, you can select these actions from a context menu. To open the context menu, right-click anywhere in the report.



This table lists keyboard shortcuts that help you navigate between panes and tabs in the code generation report. To advance through data in the selected pane, use the **Tab** key. These keyboard shortcuts override the keyboard shortcut settings in your MATLAB preferences. See “Define Keyboard Shortcuts”.

To select	Use
MATLAB code tab	**Ctrl+M**
Call stack tab	**Ctrl+K**
Code Pane	**Ctrl+W**
Summary Tab	**Ctrl+S**
All Messages Tab	**Ctrl+A**
Variables Tab	**Ctrl+V**

Searching in the MATLAB Function Report

Use the keyboard shortcut associated with `Find` in your MATLAB preferences. The default keyboard shortcut for `Find` on a Windows platform is **Ctrl+F**.

Report Limitations

The report displays information about the variables and expressions in your MATLAB code with the following limitations:

varargin and varargout

The report does not support `varargin` and `varargout` arrays.

Loop Unrolling

The report does not display full information for unrolled loops. It displays data types of one arbitrary iteration.

Dead Code

The report does not display information about dead code.

Structures

The report does not provide complete information about structures.

- The report does not provide information about all structure fields in the `struct()` constructor.
- If a structure has a nonscalar field, and an expression accesses an element of this field, the report does not provide information for the field.

Column Headings on the Variables Tab

If you scroll through the list of variables, the report does not display the column headings on the **Variables** tab.

Multiline Matrices

On the **MATLAB code** pane, the report does not support selection of multiline matrices. It supports only selection of individual lines at a time. For example, if you place your cursor over the following matrix, you cannot select the entire matrix.

```
out1 = [1 2 3;
        4 5 6];
```

The report does support selection of single line matrices.

```
out1 = [1 2 3; 4 5 6];
```

Type Function Arguments

In this section...
“About Function Arguments” on page 39-59
“Specifying Argument Types” on page 39-59
“Inheriting Argument Data Types” on page 39-61
“Built-In Data Types for Arguments” on page 39-62
“Specifying Argument Types with Expressions” on page 39-62
“Specifying Fixed-Point Designer Data Properties” on page 39-63

About Function Arguments

You create function arguments for a `MATLAB Function` block by entering them in its function header in the MATLAB Function Block Editor. When you define arguments, the Simulink software creates corresponding ports on the `MATLAB Function` block that you can attach to signals. You can select a *data type mode* for each argument that you define for a `MATLAB Function` block. Each data type mode presents its own set of options for selecting a *data type*.

By default, the data type mode for `MATLAB Function` block function arguments is **Inherited**. This means that the function argument inherits its data type from the incoming or outgoing signal. To override the default type, you first choose a data type mode and then select a data type based on the mode.

Specifying Argument Types

To specify the type of a `MATLAB Function` block function argument:

1. From the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager.

2. In the left pane, select the argument of interest.
3. In the **Data** properties dialog box (right pane), click the Show data type assistant button to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box changes dynamically to display additional fields for specifying the data type associated with the mode.

4 Based on the mode you select, specify a desired data type:

Mode	What to Specify
`Inherit` (default)	You cannot specify a value. The data type is inherited from previously-defined data, based on the scope you selected for the `MATLAB Function` block function argument: • If scope is **Input**, data type is inherited from the input signal on the designated port. • If scope is **Output**, data type is inherited from the output signal on the designated port. • If scope is **Parameter**, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace. See "Inheriting Argument Data Types" on page 39-61.
`Built in`	Select from the drop-down list of supported data types, as described in "Built-In Data Types for Arguments" on page 39-62.
`Fixed point`	Specify the fixed-point data properties as described in "Specifying Fixed-Point Designer Data Properties" on page 39-63.
`Expression`	Enter an expression that evaluates to a data type, as described in "Specifying Argument Types with Expressions" on page 39-62.
`Bus Object`	In the **Bus object** field, enter the name of a `Simulink.Bus` object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See "How Structure Inputs and Outputs Interface with Bus Signals" on page 39-77. **Note:** You can click the **Edit** button to create or modify `Simulink.Bus` objects using the Simulink Bus Editor (see "Attach Bus Signals to MATLAB Function Blocks" on page 39-75.
`Enumerated`	In the Enumerated field, enter the name of a `Simulink.IntEnumType` object that you define in the base workspace. See "Enumerated Types Supported in

Mode	What to Specify
	MATLAB Function Blocks" on page 39-102 and "Define Enumerated Data Types for MATLAB Function Blocks" on page 39-105.

Inheriting Argument Data Types

`MATLAB Function` block function arguments can inherit their data types, including fixed point types, from the signals to which they are connected. , and set data type mode using one of these methods:

1. Select the argument of interest in the Ports and Data Manager
2. In the **Data** properties dialog, select `Inherit: Same as Simulink` from the **Type** drop-down menu.

See "Built-In Data Types for Arguments" on page 39-62 for a list of supported data types.

Note An argument can also inherit its complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

After you build the model, the **Compiled Type** column of the Ports and Data Manager gives the actual type inherited from Simulink in the compiled simulation application.

The inherited type of output data is inferred from diagram actions that store values in the specified output. In the preceding example, the variables `mean` and `stdev` are computed from operations with double operands, which yield results of type `double`. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

Note Library `MATLAB Function` blocks can have inherited data types, sizes, and complexities like ordinary `MATLAB Function` blocks. However, all instances of the library block in a given model must have inputs with the same properties.

Built-In Data Types for Arguments

When you select **Built-in** for **Data type mode**, the **Data** properties dialog displays a **Data type** field that provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

Data Type	Description
`double`	64-bit double-precision floating point
`single`	32-bit single-precision floating point
`int32`	32-bit signed integer
`int16`	16-bit signed integer
`int8`	8-bit signed integer
`uint32`	32-bit unsigned integer
`uint16`	16-bit unsigned integer
`uint8`	8-bit unsigned integer
`boolean`	Boolean (1 = `true`; 0 = `false`)

Specifying Argument Types with Expressions

You can specify the types of `MATLAB Function` block function arguments as expressions in the Ports and Data Manager.

1. Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog.
2. In the **Type** field, replace "*`<data type expression>`*" with an expression that evaluates to a data type. The following expressions are allowed:

   - Alias type from the MATLAB workspace, as described in "Creating a Data Type Alias".
   - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type
   - `type` operator, to base the type on previously defined data

Specifying Fixed-Point Designer Data Properties

`MATLAB Function` blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in `MATLAB Function` blocks, you must install the Fixed-Point Designer product on your system.

You can set the following fixed-point properties:

Signedness. Select whether you want the fixed-point data to be `Signed` or `Unsigned`. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is `Signed`.

Word length. Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

Scaling. Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

Scaling Mode	Description
`Binary point` (default)	If you select this mode, the Data Type Assistant displays the **Fraction Length** field, specifying the binary point location. Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:  The default is 0.
`Slope and bias`	If you select this mode, the Data Type Assistant displays fields for entering the **Slope** and **Bias**.

Scaling Mode	Description
	• Slope can be any *positive* real number. The default is 1.0. • Bias can be any real number. The default value is 0.0. You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.

Note: You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

Data type override. Specify whether the data type override setting is `Inherit` (default) or `Off`.

Calculate Best-Precision Scaling. The Simulink software can automatically calculate "best-precision" values for both `Binary point` and `Slope and bias` scaling, based on the Limit range properties you specify.

To automatically calculate best precision scaling values:

1. Specify **Minimum**, **Maximum**, or both Limit range properties.
2. Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

Note: The Limit range properties do not apply to `Constant` or `Parameter` scopes. Therefore, Simulink cannot calculate best-precision scaling for these scopes.

Fixed-point Details. You can view the following Fixed-point details:

Fixed-point Detail	Description
Representable maximum	The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).

Fixed-point Detail	Description
Maximum	The maximum value specified.
Minimum	The minimum value specified.
Representable minimum	The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).
Precision	The precision for the given word length and fraction length (or slope and bias).

Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to `Double` or `Single` in Simulink, the `MATLAB Function` block sets the type of all inherited input signals and parameters to `fi double` or `fi single` objects respectively (see "MATLAB Function Block with Data Type Override" for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager (see "Ports and Data Manager" on page 39-34) to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

Note: If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

How Do I Set Data Type Override?

To set Data Type Override, follow these steps:

1. From the Simulink **Analysis** menu, select **Fixed-Point Tool**.
2. Set the value of the **Data type override** parameter to `Double` or `Single`.

- “Size Function Arguments” on page 39-67

Size Function Arguments

In this section...
"Specifying Argument Size" on page 39-67
"Inheriting Argument Sizes from Simulink" on page 39-67
"Specifying Argument Sizes with Expressions" on page 39-68

Specifying Argument Size

To examine or specify the size of an argument, follow these steps:

1. From the MATLAB Function Block Editor, select **Edit Data**.
2. Enter the size of the argument in the **Size** field of the Data properties dialog, located in the **General** pane.

> **Note:** The default value is `-1`, indicating that size is inherited, as described in "Inheriting Argument Sizes from Simulink" on page 39-67.

Inheriting Argument Sizes from Simulink

Size defaults to `-1`, which means that the data argument inherits its size from Simulink based on its scope:

For Scope	Inherits Size
`Input`	From the Simulink input signal connected to the argument.
`Output`	From the Simulink output signal connected to the argument.
`Parameter`	From the Simulink or MATLAB parameter to which it is bound. See "Add Parameter Arguments" on page 39-71.

After you compile the model, the **Compiled Size** column in the **Contents** pane displays the actual size used in the compiled simulation application.

The size of an output argument is the size of the value that is assigned to it. If the expected size in the Simulink model does not match, a mismatch error occurs during compilation of the model.

Note: No arguments with inherited sizes are allowed for `MATLAB Function` blocks in a library.

Specifying Argument Sizes with Expressions

The size of a data argument can be a scalar value or a MATLAB vector of values.

To specify size as a scalar, set the **Size** field to 1 or leave it blank. To specify **Size** as a vector, enter an array of up to two dimensions in `[row column]` format where

- Number of dimensions equals the length of the vector.
- Size of each dimension corresponds to the value of each element of the vector.

For example, a value of `[2 4]` defines a 2-by-4 matrix. To define a row vector of size 5, set the **Size** field to `[1 5]`. To define a column vector of size 6, set the **Size** field to `[6 1]` or just `6`. You can enter a MATLAB expression for each `[row column]` element in the **Size** field. Each expression can use one or more of the following elements:

- Numeric constants
- Arithmetic operators, restricted to `+`, `-`, `*`, and `/`
- Parameters
- Calls to the MATLAB functions `min`, `max`, and `size`

The following examples are valid expressions for **Size**:

```
k+1
size(x)
min(size(y),k)
```

In these examples, `k`, `x`, and `y` are variables of scope `Parameter`.

Once you build the model, the **Compiled Size** column displays the actual size used in the compiled simulation application.

Units in MATLAB Function Blocks

In this section...
"Units for Input and Output Data" on page 39-70
"Consistency Checking" on page 39-70
"Units for Stateflow Limitations" on page 39-70

Units for Input and Output Data

`MATLAB Function` blocks support the specification of physical units as properties for data inputs and outputs. Specify units by using the **Unit (e.g., m, m/s^2, N*m)** parameter. When you start typing in the unit field, this parameter provides matching suggestions for units that Simulink supports. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. If you select the **Data must resolve to Simulink signal object** property for output data, you cannot specify units. In this case, output data is assigned the same unit type as the Simulink signal connected to the output port.

To display the units on the Simulink lines in the model, select **Display > Signals and Ports > Port Units**.

Consistency Checking

`MATLAB Function` blocks check the consistency of the signal line unit from Simulink with the unit setting for the corresponding input or output data in the block. If the units do not match, Simulink displays a warning during model update.

Units for Stateflow Limitations

The unit property settings do not affect the execution of the `MATLAB Function` block. Simulink checks only consistency with the corresponding Simulink signal line connected to the input or output. It does not check consistency of assignments inside the `MATLAB Function` blocks. For example, Simulink does not warn against an assignment of an input with unit set to `ft` to an output with unit set to `m`. A `MATLAB Function` block does not perform unit conversions.

More About

- "Unit Specification in Simulink Models" on page 9-2

Add Parameter Arguments

Parameter arguments for `MATLAB Function` blocks do not take their values from signals in the Simulink model. Instead, Simulink searches up the workspace hierarchy. Simulink first looks in a masked workspace if the `MATLAB Function` block or a parent subsystem is masked. If the value is not found, it next looks in the model workspace and then the MATLAB base workspace.

You can provide a custom interface for parameters by masking the `MATLAB Function` block. Creating a mask for a block allows you to define the access for each parameter.

1. In the MATLAB Function Block Editor, add an argument to the function header of the `MATLAB Function` block. The name of the argument must match the name of the masked parameter or MATLAB variable that you want to pass to the `MATLAB Function` block.

   The new argument appears as an input port on the `MATLAB Function` block in the model.
2. In the `MATLAB Function` Block Editor, click **Edit Data**.
3. Select the new argument.
4. Set **Scope** to `Parameter` and click **Apply**.

   The input port for the parameter argument no longer appears in the `MATLAB Function` block.

Note: Parameter arguments appear as arguments in the function header of the `MATLAB Function` block to maintain MATLAB consistency. As a result, you can test functions in a `MATLAB Function` block by copying and pasting them to MATLAB.

Resolve Signal Objects for Output Data

In this section...
"Implicit Signal Resolution" on page 39-72
"Eliminating Warnings for Implicit Signal Resolution in the Model" on page 39-72
"Disabling Implicit Signal Resolution for a MATLAB Function Block" on page 39-72
"Forcing Explicit Signal Resolution for an Output Data Signal" on page 39-73

Implicit Signal Resolution

`MATLAB Function` blocks participate in signal resolution with Simulink signal objects. By default, output data from `MATLAB Function` blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See "Symbol Resolution" on page 4-97 and "Explicit and Implicit Symbol Resolution" on page 4-100 for more information.

Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

1. In the Simulink Editor, select **Simulation > Model Configuration Parameters**.

   The Configuration Parameters dialog appears.
2. In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.

   Data Validity configuration parameters appear in the right pane.
3. In the Signal resolution field, select **Explicit and implicit**.

Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a `MATLAB Function` block in your model, follow these steps:

1. Right-click the `MATLAB Function` block and select **Block Parameters (Subsystem)** in the context menu.

   The Block Parameters dialog opens.
2. In the Permit hierarchical resolution field, select **ExplicitOnly** or **None**, and click **OK**.

Forcing Explicit Signal Resolution for an Output Data Signal

To force signal resolution for an output signal in a `MATLAB Function` block, follow these steps:

1. In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
2. In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
3. Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

Types of Structures in MATLAB Function Blocks

In `MATLAB Function` blocks, you can define structure data as inputs or outputs that interact with bus signals. `MATLAB Function` blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of `MATLAB Function` blocks.

The following table summarizes how to create different types of structures in `MATLAB Function` blocks:

Scope	How to Create	Details
Input	Create structure data with scope of `Input`.	You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See "Create Structures in MATLAB Function Blocks" on page 39-81.
Output	Create structure data with scope of `Output`.	
Local	Create a local variable implicitly in a MATLAB function.	See "Define Scalar Structures for Code Generation" on page 49-4.
Persistent	Declare a variable to be persistent in a MATLAB function.	See "Make Structures Persistent" on page 49-8.
Parameter	Create structure data with scope of `Parameter`.	See "Define and Use Structure Parameters" on page 39-88.

Structures in `MATLAB Function` blocks can contain fields of any type and size, including muxed signals, buses, and arrays of structures.

Attach Bus Signals to MATLAB Function Blocks

For an example of how to use structures in a `MATLAB Function` block, open the model emldemo_bus_struct.

In this model, a `MATLAB Function` block receives a bus signal using the structure `inbus` at input port 1 and outputs two bus signals from the structures `outbus` at output port 1 and `outbus1` at output port 2. The input signal comes from the `Bus Creator` block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another `Bus Creator` block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structure `outbus` connects to a `Bus Selector` block `BusSelector1`; the structure `outbus1` connects to another `Bus Selector` block `BusSelector3`.

To explore the MATLAB function `fcn`, double-click the `MATLAB Function` block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output `outbus`. It initializes the second output `outbus1` to the value of field `ele3` of structure `inbus`.

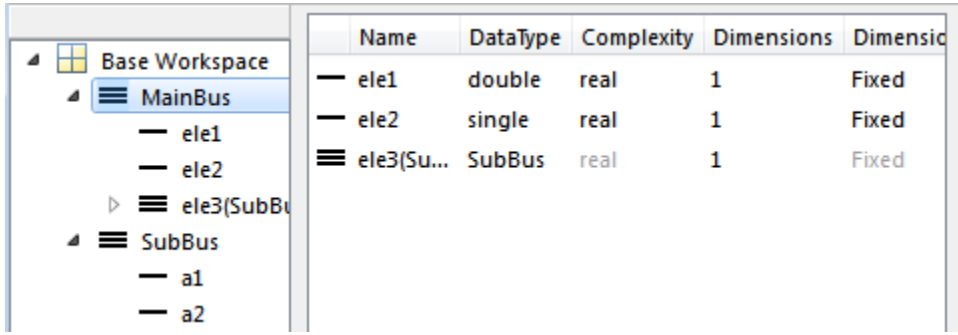
Structure Definitions in Example

Here are the definitions of the structures in the `MATLAB Function` block in the example, as they appear in the Ports and Data Manager:

Name	Scope	Port	Resolve Signal	DataType	Size
inbus	Input	1		Inherit: Same as Simulink	-1
outbus	Output	1		Bus: MainBus	1
outbus1	Output	2		Bus: SubBus	1

Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 39-81). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:



The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see "Index Substructures and Fields" on page 39-79). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

Structure	First Field	Second Field	Third Field
`inbus`	`inbus.ele1`	`inbus.ele2`	`inbus.ele3`
`outbus`	`outbus.ele1`	`outbus.ele2`	`outbus.ele3`
`outbus1`	`outbus1.a1`	`outbus1.a2`	—

How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the `MATLAB Function` block as structures; structure outputs from the `MATLAB Function` block appear as buses in Simulink models. When you create structure inputs, the `MATLAB Function` block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from `MATLAB Function` blocks to any bus signal, including:

- Blocks that output bus signals — such as `Bus Creator` blocks
- Blocks that accept bus signals as input — such as `Bus Selector` and `Gain` blocks
- `S-Function` blocks
- Other `MATLAB Function` blocks

You can use global bus type data in Data Store Memory blocks with `MATLAB Function` blocks. For more information on using buses and Data Store Memory, see "Data Stores with Buses and Arrays of Buses" on page 60-29.

Working with Virtual and Nonvirtual Buses

`MATLAB Function` blocks supports nonvirtual buses only (see "Virtual and Nonvirtual Buses" on page 63-14). For `MATLAB Function` block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in `MATLAB Function` blocks:

- For each structure input or output in a `MATLAB Function` block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- `MATLAB Function` blocks support nonvirtual buses only.

Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in `MATLAB Function` blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see "Structure Definition for Code Generation" on page 49-2).

For example, in the emldemo_bus_struct model described in "Attach Bus Signals to MATLAB Function Blocks" on page 39-75, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                  'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

Dot Notation	Symbol Resolution
`substruct.a1`	Field `a1` of local structure `substruct`
`inbus.ele3.a1`	Value of field `a1` of field `ele3`, a substructure of structure input`inbus`
`inbus.ele3.a2(1,1)`	Value in row 1, column 1 of field `a2` of field `ele3`, a substructure of structure input `inbus`

Create Structures in MATLAB Function Blocks

Here is the workflow for creating a structure in a `MATLAB Function` block:

1. Decide on the type (or scope) of the structure (see "Types of Structures in MATLAB Function Blocks" on page 39-74).
2. Based on the scope, follow these guidelines for creating the structure:

For Structure Scope:	Follow These Steps:
Input	**a** Create a `Simulink.Bus` object in the base workspace to define the structure input. **b** Add data to the `MATLAB Function` block, as described in "Adding Data to a MATLAB Function Block" on page 39-38. The data should have the following properties • **Scope** = `Input` • **Type** = `Bus: <object name>` For `<object name>`, enter the name of the `Simulink.Bus` object that defines the structure input See "Rules for Defining Structures in MATLAB Function Blocks" on page 39-78.
Output	**a** Create a `Simulink.Bus` object in the base workspace to define the structure output. **b** Add data to the `MATLAB Function` block with the following properties: • **Scope** = `Output` • **Type** = `Bus: <object name>` For `<object name>`, enter the name of the `Simulink.Bus` object that defines the structure output **c** Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in "Structure Definition for Code Generation" on page 49-2. **d** Make sure the number, type, and size of fields in the output structure variable definition match the properties of the `Simulink.Bus` object.

For Structure Scope:	Follow These Steps:
Local	Define the structure implicitly as a local variable in the MATLAB function, as described in "Structure Definition for Code Generation" on page 49-2. By default, local variables in `MATLAB Function` blocks are temporary.
Persistent	Define the structure implicitly as a persistent variable in the MATLAB function, as described in "Make Structures Persistent" on page 49-8.
Parameter	**a** Create a structure variable in the base workspace. **b** Add data to the `MATLAB Function` block with the following properties: • **Name** = same name as the structure variable you created in step 1. • **Scope** = `Parameter` See "Define and Use Structure Parameters" on page 39-88.

More About

- "What Is a MATLAB Function Block?" on page 39-5
- "Structure Definition for Code Generation" on page 49-2

Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a `MATLAB Function` block. Here are the guidelines:

Operation	Conditions
Assign one structure to another structure	You must define each structure with the same number, type, and size of fields, either as `Simulink.Bus` objects in the base workspace or locally as implicit structure declarations (see "Create Structures in MATLAB Function Blocks" on page 39-81).
Assign one structure to a substructure of a different structure and vice versa	You must define the structure with the same number, type, and size of fields as the substructure, either as `Simulink.Bus` objects in the base workspace or locally as implicit structure declarations.
Assign an element of one structure to an element of another structure	The elements must have the same type and size.

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in "Attach Bus Signals to MATLAB Function Blocks" on page 39-75:

Assignment	Valid or Invalid?	Rationale
`outbus = mystruct;`	Valid	Both `outbus` and `mystruct` have the same number, type, and size of fields. The structure `outbus` is defined by the `Simulink.Bus` object `MainBus` and `mystruct` is defined locally to match the field properties of `MainBus`.
`outbus = inbus;`	Valid	Both `outbus` and `inbus` are defined by the same `Simulink.Bus` object, `MainBus`.
`outbus1 = inbus.ele3;`	Valid	Both `outbus1` and `inbus.ele3` have the same type and size because each is defined by the `Simulink.Bus` object `SubBus`.

Assignment	Valid or Invalid?	Rationale
`outbus1 = inbus;`	Invalid	The structure `outbus1` is defined by a different `Simulink.Bus` object than the structure `inbus`.

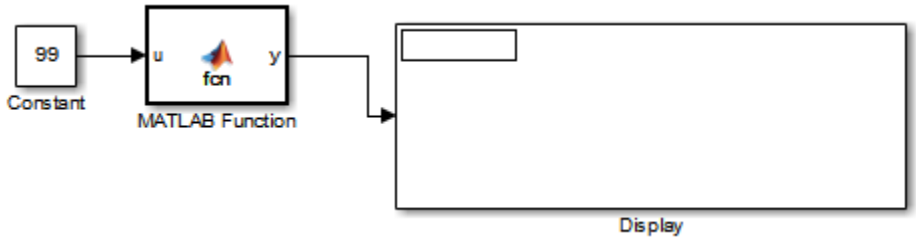
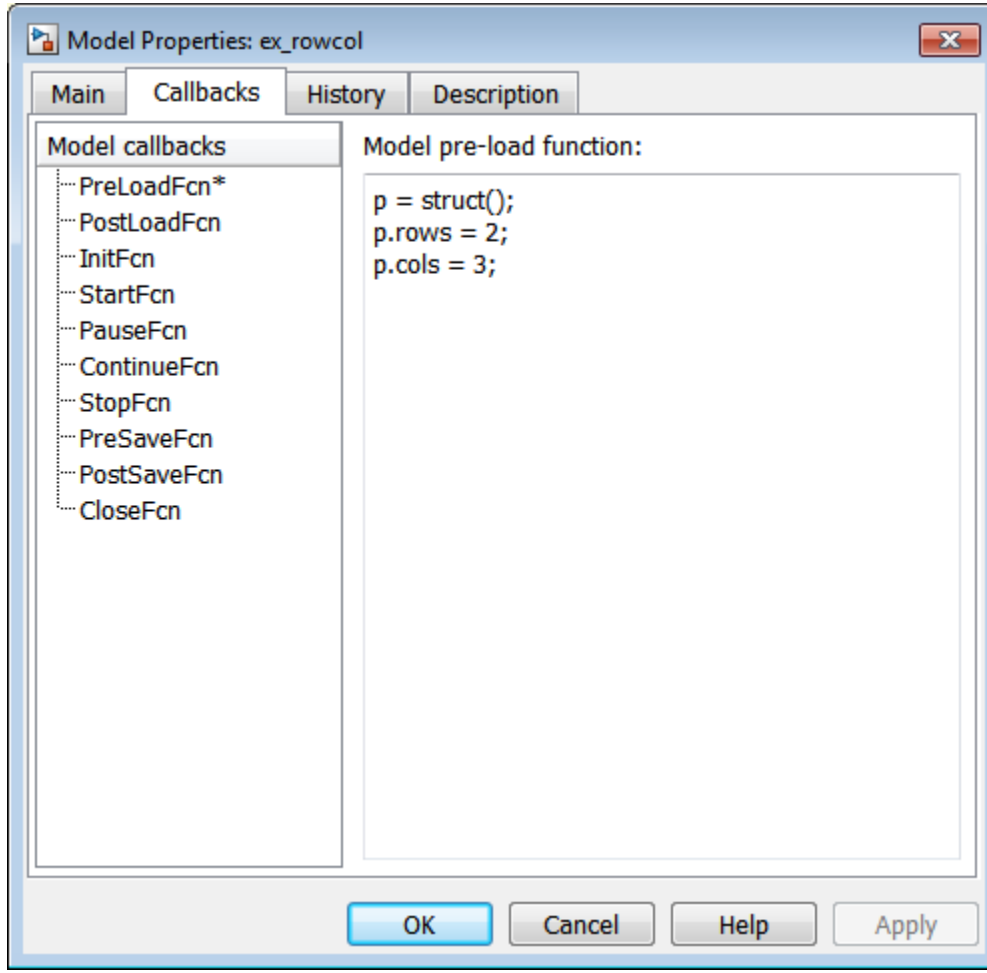
Initialize a Matrix Using a Non-Tunable Structure Parameter

The following simple example uses a non-tunable structure parameter input to initialize a matrix output. The model looks like this:



This model defines a structure variable p in its pre-load callback function, as follows:



The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The `MATLAB Function` block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix `y` to 99, the value of `u`:

Define and Use Structure Parameters

In this section...
"Defining Structure Parameters" on page 39-88
"FIMATH Properties of Non-Tunable Structure Parameters" on page 39-88

Defining Structure Parameters

To define structure parameters in `MATLAB Function` blocks, follow these steps:

1. Define and initialize a structure variable

   A common method is to create a structure in the base workspace.

2. In the Ports and Data Manager, add data in the `MATLAB Function` block with the following properties:

Property	What to Specify
Name	Enter same name as the structure variable you defined in the base workspace
Scope	Select `Parameter`
Tunable	Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter non-tunable and preserve the initial value during simulation
Type	Select `Inherit: Same as Simulink`

3. Click **Apply**.

FIMATH Properties of Non-Tunable Structure Parameters

FIMATH properties for non-tunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent `MATLAB Function` block. (These FIMATH properties appear in the properties dialog box for `MATLAB Function` blocks.)

Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in `MATLAB Function` blocks support a subset of the operations available for MATLAB structures (see "Structures").
- You cannot use variable-size data with arrays of buses (see "Array of Buses Limitations" on page 63-93).

How MATLAB Function Blocks Implement Variable-Size Data

You can define variable-size arrays and matrices as inputs, outputs, and local data in `MATLAB Function` blocks. However, the block must be able to determine the upper bounds of variable-size data at compile time.

Related Examples

- "Filter a Variable-Size Signal" on page 39-94

More About

- "What Is a MATLAB Function Block?" on page 39-5

Enable Support for Variable-Size Data

Support for variable-size data is enabled by default for `MATLAB Function` blocks. To modify this property for individual blocks:

1. In the MATLAB Function Block Editor, select **Edit Data**.
2. Select or clear the check box **Support variable-size arrays**.

Related Examples

- "Filter a Variable-Size Signal" on page 39-94

More About

- "What Is a MATLAB Function Block?" on page 39-5
- "MATLAB Function Block Editor" on page 39-32
- "How MATLAB Function Blocks Implement Variable-Size Data" on page 39-91

Declare Variable-Size Inputs and Outputs

1. In the MATLAB Function Block Editor, select **Edit Data**.
2. Select **Add** > **Data**
3. Select the **Variable size** check box.
4. Set **Scope** as either `Input` or `Output`.
5. Enter size:

For:	What to Specify
Input	Enter `-1` to inherit size from Simulink or specify the explicit size and upper bound. For example, enter `[2 4]` to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 4 for the second.
Output	Specify the explicit size and upper bound.

Filter a Variable-Size Signal

In this section...
“About the Example” on page 39-94
“Simulink Model” on page 39-94
“Source Signal” on page 39-95
“MATLAB Function Block: uniquify” on page 39-95
“MATLAB Function Block: avg” on page 39-97
“Variable-Size Results” on page 39-98

About the Example

The following example appears throughout this section to illustrate how `MATLAB Function` blocks exchange variable-size data with other Simulink blocks. The model uses a variable-size vector to store the values of a white noise signal. The size of the vector may vary at run time as the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other
- Average every two signal values and output only the resulting means

Simulink Model

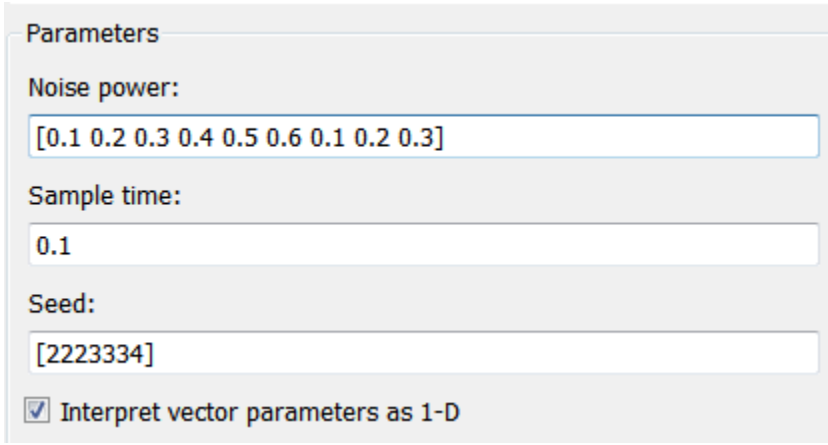
Open the example model by typing `emldemo_process_signal` at the MATLAB command prompt. The model contains the following blocks:

Simulink Block	Description
Band-Limited White Noise	Generates a set of normally distributed random values as the source of the white noise signal.
MATLAB Function `uniquify`	Filters out signal values that are not unique to within a specified tolerance of each other.
MATLAB Function `avg`	Outputs the average of a specified number of unique signal values.
Unique values	Scope that displays the unique signal values output from the `uniquify` function.

Simulink Block	Description
Average values	Scope that displays the average signal values output from the `avg` function.

Source Signal

The band-limited white noise signal has these properties:



The size of the noise power value defines the size of the matrix that holds the signal values — in this case, a 1-by-9 vector of double values.

MATLAB Function Block: uniquify

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

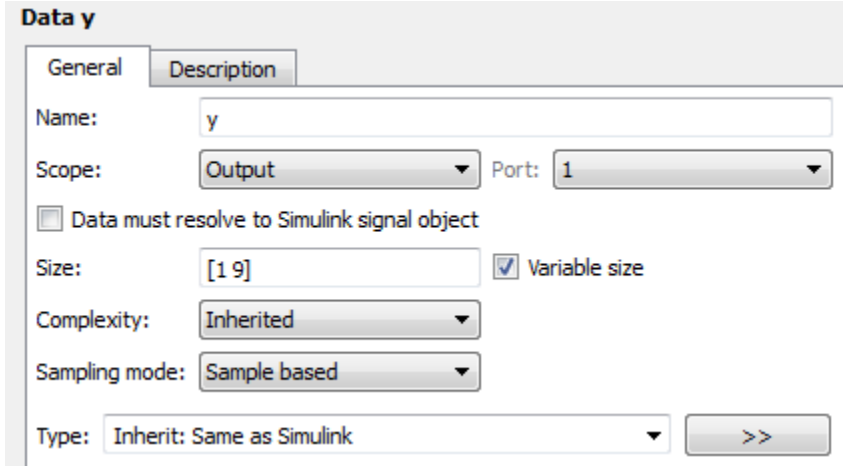
```
function B = emldemo_uniquetol(A,tol) %#codegen
```

```
A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that `abs(B(i) - B(j)) > tol` for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify` block must also be variable sized so it can pass the values returned from `emldemo_uniquetol` to the **Unique values** scope. Here are the properties of `y`:



For variable-size outputs, you must specify an explicit size and upper bound, shown here as [1 9].

MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block as follows:

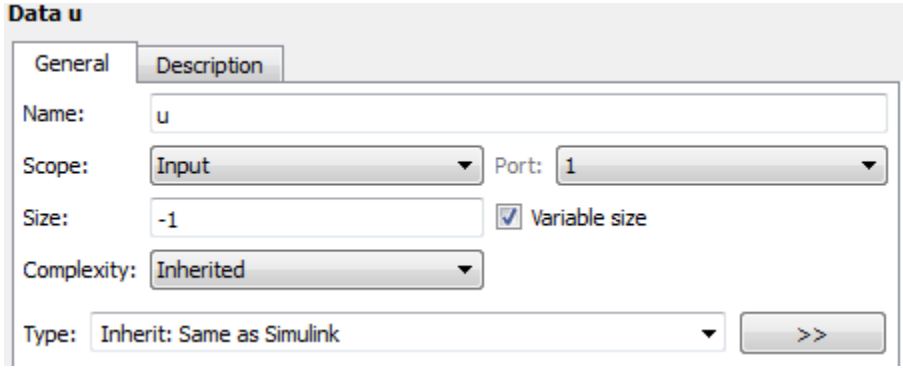
If number of signal values:	The MATLAB Function block:
> 1 and divisible by 2	Averages every consecutive pair of values
> 1 but *not* divisible by 2	Drops the first (smallest) value and average the remaining consecutive pairs
= 1	Returns the value unchanged

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
    y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.



The `avg` function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen

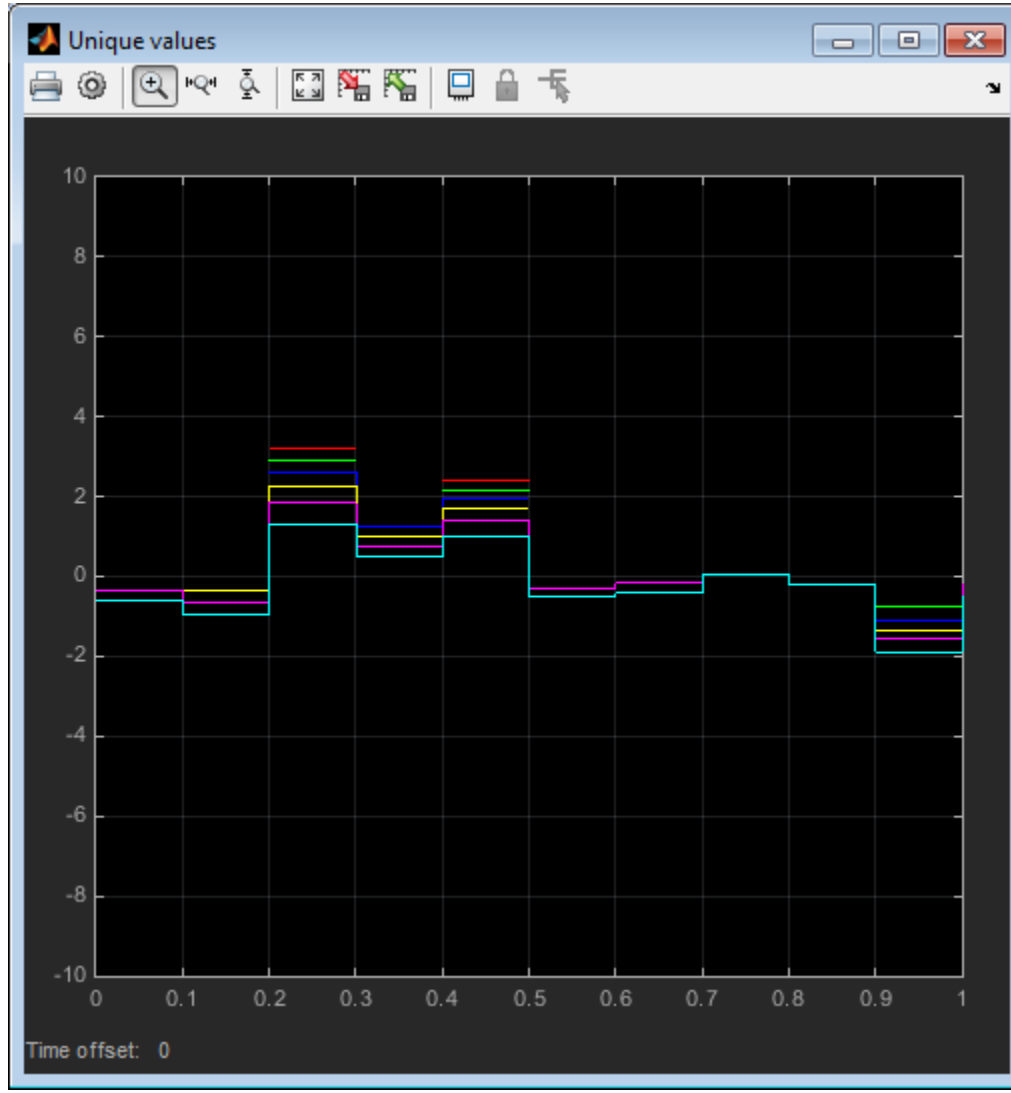
assert(n>=1 && n<=numel(A));

B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
     B(i) = mean(A(k + (0:n-1)));
     k = k + n;
end
```

Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:



- The `avg` block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

Enumerated Types Supported in MATLAB Function Blocks

An enumerated type is a user-defined type whose values belong to a predefined set of enumerated values. Each enumerated value consists of a name and an underlying numeric value. For basic information about using enumerated data types in Simulink, see "Use Enumerated Data in Simulink Models" on page 58-7.

You can define an enumerated data type in an enumeration class definition file. For use in a `MATLAB Function` block, you must base the class on `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

In this example, the statement `classdef PrimaryColors < Simulink.IntEnumType` means that the enumerated type `PrimaryColors` is based on the `Simulink.IntEnumType` class. `PrimaryColors` inherits the characteristics of the `Simulink.IntEnumType` class. It also defines its own unique characteristics. For example, `PrimaryColors` is restricted to three enumerated values.

Enumerated Value	Enumerated Name	Underlying Numeric Value
`Red(1)`	`Red`	1
`Blue(2)`	`Blue`	2
`Yellow(4)`	`Yellow`	4

If the enumerated type inherits from a base type supported for a `MATLAB Function` block, you can exchange enumerated data between `MATLAB Function` blocks and other Simulink blocks in a model.

You can also define an enumerated type by using the function `Simulink.defineIntEnumType`.

Enumeration Class Base Types in `MATLAB Function` Block

For `MATLAB Function` blocks, you must base an enumerated type on the `Simulink.IntEnumType` class or one of the following built-in MATLAB integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`

You can use the base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.
- Reduce memory usage.
- Interface to legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

C Code Representation for `Simulink.IntEnumType` Base Type

If the base type is `Simulink.IntEnumType` , the code generation software generates a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
  GREEN = 1,
```

```
  RED
} LEDcolor;
```

C Code Representation for Built-In Integer Base Types

For built-in integer base types, the code generation software generates a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16
    enumeration
        GREEN(1),
        RED(2)
    end
 end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;

#define GREEN                          ((LEDcolor)1)
#define RED                            ((LEDcolor)2)
```

Define Enumerated Data Types for MATLAB Function Blocks

You can define enumerated data types for `MATLAB Function` blocks in two ways:

- Use the `Simulink.defineIntEnumType` function. See "Import Enumerations Defined Externally to MATLAB" on page 58-12.
- Define an enumerated type in a class definition file.

Define Enumerated Type in Class Definition File

1. Create a class definition file.

   In the Command Window, select **File** > **New** > **Class**.

2. Enter the class definition:

   ```
   classdef EnumTypeName < BaseType
   ```

   `EnumTypeName` is a case-sensitive string that must be unique among data type names and workspace variable names. *`BaseType`* must be `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`.

   For example, the following code defines an enumerated type called `sysMode` that inherits from the built-in type `Simulink.IntEnumType`:

   ```
   classdef sysMode < Simulink.IntEnumType
       ...
   end
   ```

3. Define enumerated values in an `enumeration` section:

   ```
   classdef EnumTypeName < BaseType
     enumeration
       EnumName(N)
       ...
     end
   end
   ```

   For example, the following code defines a set of two values for enumerated type `LEDcolor`:

   ```
   classdef LEDcolor < Simulink.IntEnumType
       enumeration
   ```

```
            GREEN(1),
            RED(2),
        end
    end
```

4 Save the file on the MATLAB path.

The name of the file must match the name of the enumerated data type. The match is case sensitive.

Add Inputs, Outputs, and Parameters as Enumerated Data

You can add inputs, outputs, and parameters as enumerated data, according to these guidelines:

For:	Do This:
Inputs	Inherit from the enumerated type of the connected Simulink signal or specify the enumerated type explicitly.
Outputs	Always specify the enumerated type explicitly.
Parameters	For tunable parameters, specify the enumerated type explicitly. For non-tunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a `MATLAB Function` block:

1. In the MATLAB Function Block Editor, select **Edit Data**.
2. In the Ports and Data Manager, select **Add** > **Data**.
3. In the **Name** field, enter a name for the enumerated data.

   For parameters, the name must match the enumerated masked parameter or workspace variable name.
4. In the **Type** field, specify an enumerated type.

   To specify an explicit enumerated type:

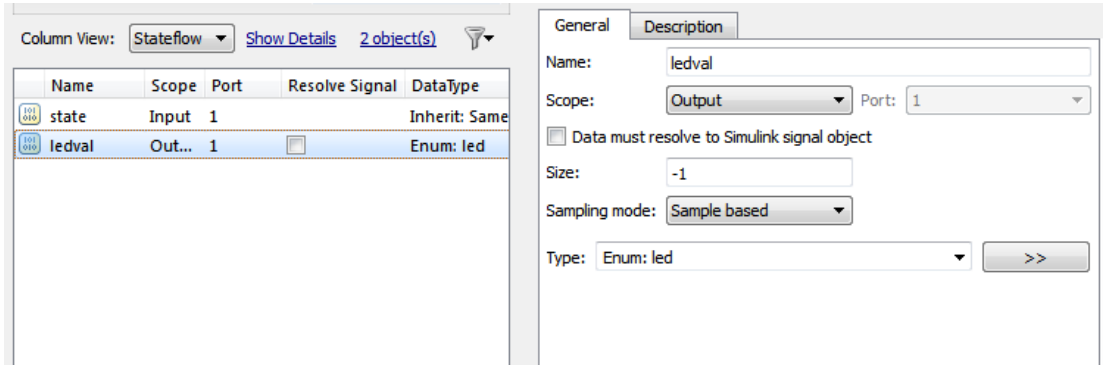
   a. Select `Enum:<class name>` from the drop-down menu in the **Type** field.

   b. Replace `<class name>` with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

      For example, you can enter `Enum:led` in the **Type** field.

      Note: The **Complexity** field disappears when you select `Enum:<class name>` because enumerated data types do not support complex values.

      For example, the following output `ledval` has an explicit enumerated type, `led`:



To inherit the enumerated type from a connected Simulink signal (for inputs only):

a Select `Inherit:Same as Simulink` from the drop-down menu in the **Type** field.

For example, the following input `state` inherits its enumerated type `switchmode` from a Simulink signal:

Name	Scope	Port	Resolve Signal	DataType	Compiled Type
ledval	Output	1		Enum: led	led
state	Input	1		Inherit: Same as Simulink	switchmode

5 Click **Apply**.

Instantiate Enumerated Data in MATLAB Function Blocks

To instantiate an enumerated type in a `MATLAB Function` block, use dot notation to specify *`ClassName.EnumName`*. For example, the following MATLAB function `checkState` instantiates the enumerated types `switchmode` and `led` from "Control an LED Display" on page 39-111. The dot notation appears highlighted in the code.

```
function led = checkState(state)
%#codegen

if state == switchmode.ON
    led = led.GREEN;
else
    led = led.RED;
end
```

Control an LED Display

In this section...

"About the Example" on page 39-111
"Class Definition: switchmode" on page 39-111
"Class Definition: led" on page 39-111
"Simulink Model" on page 39-112
"MATLAB Function Block: checkState" on page 39-113
"How the Model Displays Enumerated Data" on page 39-114

About the Example

The following example illustrates how `MATLAB Function` blocks exchange enumerated data with other Simulink blocks. This simple model uses enumerated data to represent the modes of a device that controls the colors of an LED display. The `MATLAB Function` block receives an enumerated data input representing the mode and, in turn, outputs enumerated data representing the color to be displayed by the LED.

This example uses two enumerated types: `switchmode` to represent the set of allowable modes and `led` to represent the set of allowable colors. Both type definitions inherit from the built-in type `Simulink.IntEnumType` and must reside on the MATLAB path.

Class Definition: switchmode

Here is the class definition of the `switchmode` enumerated data type:

```
classdef switchmode < Simulink.IntEnumType
  enumeration
    OFF(0)
    ON(1)
  end
end
```

This definition must reside on the MATLAB path in a MATLAB file with the same name as the class, `switchmode.m`.

Class Definition: led

Here is the class definition of the `led` enumerated data type:

```
classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8)
    end
end
```

This definition must reside on the MATLAB path in a file called `led.m`. The set of allowable values do not need to be consecutive integers.

Simulink Model

Open the example model by typing `emldemo_led_switch` at the MATLAB command prompt. The model contains the following blocks:

Simulink Block	Description
`Step`	Provides source of the on/off signal. Outputs an initial value of 0 (off) and at 10 seconds steps up to a value of 1 (on).
`Data Type Conversion` from `double` to `int32`	Converts the `Step` signal of type `double` to type `int32`.
`Data Type Conversion` from `int32` to enumerated type `switchmode`	Converts the value of type `int32` to the enumerated type `switchmode`. In the `Data Type Conversion` block, you specify the enumerated data type using the prefix `Enum:` followed by the type name. You cannot set a minimum or maximum value for a signal of an enumerated type; leave these fields at the default value `[]`. For this example, the `Data Type Conversion` block parameters have these settings: • Output minimum: `[]` • Output maximum: `[]` • Output data type: `Enum:switchmode` For more information about specifying enumerated types in Simulink models,

Simulink Block	Description
	see "Define Enumerated Data Types for MATLAB Function Blocks" on page 39-105.
`MATLAB Function checkState`	Evaluates enumerated data input `state` to determine the color to output as enumerated data `ledval`. See "MATLAB Function Block: checkState" on page 39-113.
`Display`	Displays the enumerated value of output `led`.

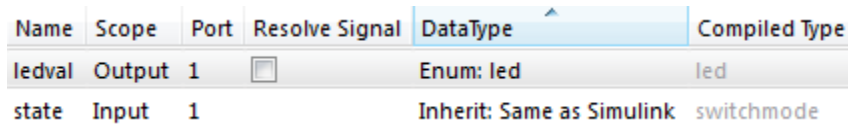
MATLAB Function Block: checkState

The function `checkState` in the `MATLAB Function` block uses enumerated data to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state and lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
%#codegen

if state == switchmode.ON
    ledval = led.GREEN;
else
    ledval = led.RED;
end
```

The input `state` inherits its enumerated type `switchmode` from the Simulink step signal; the enumerated type of output `ledval` is explicitly declared as `Enum:led`:



Explicit enumerated type declarations must include the prefix `Enum:`. For more information, see "Define Enumerated Data Types for MATLAB Function Blocks" on page 39-105.

How the Model Displays Enumerated Data

Wherever possible, Simulink displays the name of an enumerated value, not its underlying integer. For instance, Display blocks display the name of enumerated values. In this example, when the model simulates for less than 10 seconds, the step signal is 0, resulting in a red LED display to signify the off state.

Similarly, if the model simulates for 10 seconds or more, the step signal is 1, resulting in a green LED display to signify the on state.

Simulink scope blocks work differently. For more information, see “Enumerations and Scopes” on page 58-5.

Operations on Enumerated Data

Simulink software prevents enumerated values from being used as numeric values in mathematical computation.

The code generation software supports the following enumerated data operations:

- Assignment (=)
- Relational operations (==, ~=, <, >, <=, >=,)
- Cast
- Indexing

Related Examples

Enumerated Data in MATLAB Function Blocks

In this section...
"When to Use Enumerated Data" on page 39-116 "Limitations of Enumerated Types" on page 39-116

When to Use Enumerated Data

You can use enumerated types to represent program states and to control program logic, especially when you need to restrict data to a predetermined set of values and refer to these values by name. Even though you can sometimes achieve these goals by using integers or strings, enumerated types offer the following advantages:

- Provide more readable code than integers
- Allow more robust error checking than integers or strings

  For example, if you mistype the name of an element in the enumerated type, the code generation software alerts you that the element does not belong to the set of allowable values.
- Produce more efficient code than strings

  For example, comparisons of enumerated values execute faster than comparisons of strings.

Limitations of Enumerated Types

Enumerated types in `MATLAB Function` blocks are subject to the limitations imposed by the code generation software. See "Enumerated Data Definition for Code Generation" on page 51-2.

Share Data Globally

In this section...
"When Do You Need to Use Global Data?" on page 39-117
"Using Global Data with the MATLAB Function Block" on page 39-117
"Choosing How to Store Global Data" on page 39-118
"How to Use Data Store Memory Blocks" on page 39-119
"How to Use Simulink.Signal Objects" on page 39-121
"Using Data Store Diagnostics to Detect Memory Access Issues" on page 39-123
"Limitations of Using Shared Data in MATLAB Function Blocks" on page 39-123

When Do You Need to Use Global Data?

You might need to use global data with a `MATLAB Function` block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from `MATLAB Function` blocks.
- You have an existing model that uses a large amount of global data and you are adding a `MATLAB Function` block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either `Data Store Memory` blocks or Simulink.Signal objects. How you store global data depends on the number and scope of your global variables. For more information, see "Local and Global Data Stores" on page 60-3 and "Choosing How to Store Global Data" on page 39-118.

How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the `MATLAB Function` block to map the data to data store memory. This difference allows global data in MATLAB

functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different `MATLAB Function` blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

How to Use Globals with the MATLAB Function Block

To use global data in your `MATLAB Function` block, or in any code that this block calls, you must:

1. Declare a global variable in your `MATLAB Function` block, or in any code that is called by the `MATLAB Function` block.
2. Register a `Data Store Memory` block or `Simulink.Signal` object that has the same name as the global variable with the `MATLAB Function` block.

For more information, see "How to Use Data Store Memory Blocks" on page 39-119 and "How to Use Simulink.Signal Objects" on page 39-121.

Choosing How to Store Global Data

The following table summarizes whether to use `Data Store Memory` blocks or `Simulink.Signal` objects.

If you want to:	Use:	For more information:
Use a small number of global variables in a single model that does not use model reference.	`Data Store Memory` blocks. **Note:** Using `Data Store Memory` blocks scopes the data to the model.	"How to Use Data Store Memory Blocks" on page 39-119
Use a large number of global variables in a single model that does not use model reference.	`Simulink.Signal` objects defined in the model workspace.	"How to Use Simulink.Signal Objects" on page 39-121

If you want to:	Use:	For more information:
	`Simulink.Signal` objects offer these advantages: • You do not have to add numerous `Data Store Memory` blocks to your model. • You can load the `Simulink.Signal` objects in from a MAT-file.	
Share data between multiple models (including referenced models).	`Simulink.Signal` objects defined in the base workspace **Note:** If you use `Data Store Memory` blocks as well as `Simulink.Signal`, note that using `Data Store Memory` blocks scopes the data to the model.	"How to Use Simulink.Signal Objects" on page 39-121

How to Use Data Store Memory Blocks

1. Add a `MATLAB Function` block to your model.
2. Double-click the `MATLAB Function` block to open its editor.
3. Declare a global variable in the `MATLAB Function` block code, or in any MATLAB file that the `MATLAB Function` block code calls. For example:

   ```
   global A;
   ```

4. Add a `Data Store Memory` block to your model and set the following:
   a. Set the **Data store name** to match the name of the global variable in your `MATLAB Function` block code.
   b. Set **Data type** to an explicit data type.

The data type cannot be `auto`.

c Set the **Signal type**.

d Specify an **Initial value**.

The initial value of the `Data Store Memory` block cannot be unspecified.

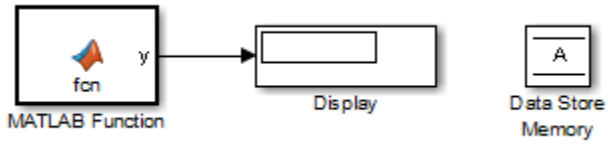
5 Register the variable to the `MATLAB Function` block.

a In the Ports and Data Manager, add data with the same name as the global variable.

b Set the **Scope** of the data to `Data Store Memory`.

For more information on using the Ports and Data Manager, see "Ports and Data Manager" on page 39-34.

Example: Using Data Store Memory with the MATLAB Function Block



This simple model demonstrates how a `MATLAB Function` block uses the global data stored in `Data Store Memory` block `A`.

1 Open the `dsm_demo` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', 'examples', 'dsm_demo.mdl')))
```

2 Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.

The `MATLAB Function` block modifies the value of global data `A` each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

3 In the MATLAB Function Block Editor, select **Edit Data**.

4 In the Ports and Data Manager, select the data `A` in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that `A` has a scope of `Data Store Memory`.

5 In the model, double-click the `Data Store Memory` block `A`.

The Block Parameters dialog box opens. Note that `A` has an initial value of `25`.

6 Simulate the model.

The `MATLAB Function` block reads the initial value of global data stored in `A` and updates the value of `A` each time it executes.

How to Use Simulink.Signal Objects

1 Create a `Simulink.Signal` object in the model workspace.

Tip Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

---

a In the Model Explorer, navigate to ***`model_name`*** > **Model Workspace** in the **Model Hierarchy** pane.

b Select **Add** > **Simulink Signal**.

c Ensure that these settings apply to the `Simulink.Signal` object:

i Set **Data type** to an explicit data type.

The data type cannot be `auto`.

ii Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or inherited.

iii Set the **Complexity**.

iv Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

2 Register the `Simulink.Signal` object to the `MATLAB Function` block.

a In the Ports and Data Manager, add data with the same name as the `Simulink.Signal` object you created in the model (or base) workspace.

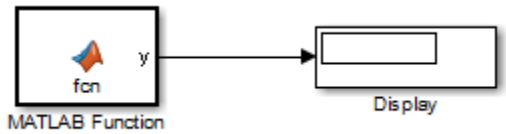
b Set the **Scope** of the data to `Data Store Memory`.

3 Declare a global variable with the same name in the code for your `MATLAB Function` block.

```
global Sig;
```

For more information on using the Ports and Data Manager, see "Ports and Data Manager" on page 39-34.

Example: Using a Simulink.Signal Object with a MATLAB Function Block



1 Open the `simulink_signal_local` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
simulink_signal_local
```

2 Double-click the `MATLAB Function` block to open its editor.

The `MATLAB Function` block modifies the value of global data `A` each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

3 From the MATLAB Function Block Editor menu, select **Edit Data**.

4 In the Ports and Data Manager, select the data `A` in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that `A` has a scope of `Data Store Memory`.

5 From the model menu, select **View** > **Model Explorer**.

6 In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

7 Click the `Simulink.Signal` object `A`.

The right pane displays attributes for `A`, including.

Attribute	Value
Data type	`double`
Complexity	`real`
Dimensions	`1`
Initial value	`5`

8 Simulate the model.

The `MATLAB Function` block reads the initial value of global data stored in `A` and updates the value of `A` each time it executes.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the `Data Store Memory` block. These diagnostics are available for `Data Store Memory` blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 60-3.

Note: If you pass data store memory arrays to functions, optimizations such as `A=foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

Limitations of Using Shared Data in MATLAB Function Blocks

There is no `Data Store Memory` support for:

- MATLAB structures

- Variable-sized data

Create Custom Block Libraries

In this section...

"When to Use MATLAB Function Block Libraries" on page 39-125
"How to Create Custom MATLAB Function Block Libraries" on page 39-125
"Example: Creating a Custom Signal Processing Filter Block Library" on page 39-126
"Code Reuse with Library Blocks" on page 39-138
"Debugging MATLAB Function Library Blocks" on page 39-143
"Properties You Can Specialize Across Instances of Library Blocks" on page 39-143

When to Use MATLAB Function Block Libraries

In Simulink, you can create your own block libraries as a way to reuse the functionality of blocks or subsystems in one or more models. If you want to reuse a set of MATLAB algorithms in Simulink models, you can encapsulate your MATLAB code in a `MATLAB Function` block library.

As with other Simulink block libraries, you can specialize each instance of `MATLAB Function` library blocks in your model to use different data types, sample times, and other properties. Library instances that inherit the same properties can reuse generated code

How to Create Custom MATLAB Function Block Libraries

Here is a basic workflow for creating custom block libraries with `MATLAB Function` blocks. To work through these steps with an example, see "Example: Creating a Custom Signal Processing Filter Block Library" on page 39-126.

1. Add polymorphic MATLAB code to `MATLAB Function` blocks in a Simulink model.

   Polymorphic code is code that can process data with different properties, such as type, size, and complexity.
2. Configure the blocks to inherit the properties you want to specialize.

   For a list of properties you can specialize, see "Properties You Can Specialize Across Instances of Library Blocks" on page 39-143.

3 Optionally, customize your library code using masking.

4 Add instances of `MATLAB Function` library blocks to a Simulink model.

Note: If your `MATLAB Function` block library is masked, you cannot modify contents of the block with mask initialization code. The **Allow library block to modify its contents** option in the Mask dialog box is not support for `MATLAB Function` block libraries.

Example: Creating a Custom Signal Processing Filter Block Library

- "What You Will Learn" on page 39-126
- "About the Filter Algorithms" on page 39-126
- "Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks" on page 39-127
- "Step 2: Configure Blocks to Inherit Properties You Want to Specialize" on page 39-128
- "Step 3: Customize Your Library Using Masking" on page 39-129
- "Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model" on page 39-133

What You Will Learn

This simple example takes you through the workflow described in "How to Create Custom MATLAB Function Block Libraries" on page 39-125 to show you how to:

- Create a library of signal processing filter algorithms using `MATLAB Function` blocks
- Customize one of the library blocks using mask parameters
- Convert one of the filter algorithms to source-protected P-code that you can call from a `MATLAB Function` library block

About the Filter Algorithms

The MATLAB filter algorithms are:

my_fft

Performs a discrete Fourier transform on an input signal. The input can be a vector, matrix, or multidimensional array whose length is a power of 2.

my_conv

Convolves two input vector signals. Outputs a subsection of the convolution with a size specified by a mask parameter, `Shape`.

my_sobel

Convolves a 2D input matrix with a Sobel edge detection filter.

Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks

1. In Simulink, create a library model by selecting **File > New > Library**
2. Drag three `MATLAB Function` blocks into the model from the User-Defined Functions section of the Simulink Library Browser and name them:
   - `my_fft_filter`
   - `my_conv_filter`
   - `my_sobel_filter`
3. Save the library model as `my_filter_lib`.
4. Open the `MATLAB Function` block named `my_fft_filter`, replace the template code with the following code, and save the block:

   ```
   function y = my_fft(x)

   y = fft(x);
   ```
5. Replace the template code in `my_conv_filter` block with the following code and save the block:

   ```
   function c = my_conv(a, b)

   c = conv(a, b);
   ```
6. Replace the template code in `my_sobel_filter` block with the following code and save the block:

   ```
   function y = my_sobel(u)

   %% "my_sobel_filter" is a MATLAB function
   %%  on the  MATLAB path.
   y = my_sobel_filter(u);
   ```

   The `my_sobel` function acts as a wrapper that calls a MATLAB function, `my_sobel_filter`, on the code generation path. `my_sobel_filter` implements

the algorithm that convolves a 2D input matrix with a Sobel edge detection filter. By calling the function rather than inlining the code directly in the `MATLAB Function` block, you can reuse the algorithm both as MATLAB code and in a Simulink model. You will create `my_sobel_filter` next.

7 In the same folder where you created `my_filter_lib`, create a new MATLAB function `my_sobel_filter` with the following code:

```
function y = my_sobel_filter(u)

% Sobel edge detection filter
h = [1     2     1;...
     0     0     0;...
    -1    -2    -1];

y = abs(conv2(u, h));
```

Save the file as `my_sobel_filter.m`.

Step 2: Configure Blocks to Inherit Properties You Want to Specialize

In this example, the data in the signal processing filter algorithms must inherit size, type, and complexity from the Simulink model. By default, data in `MATLAB Function` blocks inherit these properties. To explicitly configure data to inherit properties:

1 Open a `MATLAB Function` block and select **Edit Data**.

2 In the left pane of the Ports and Data Manager, select the data of interest.

3 In the right pane, configure the data to inherit properties from Simulink:

To Inherit	What to Specify
Size	Enter `-1` in Size field
Complexity	Select **Inherited** from the Complexity menu
Type	Select **Inherit: Same as Simulink** from the Type menu

For example, if you open the `MATLAB Function` block `my_fft_filter` and look at the properties of input `x` in the Ports and Data Manager, you see that size, type, and complexity are inherited by default.

Note: If your design has specific requirements or constraints, you can enter values for any of these properties, rather than inherit them from Simulink. For example, if your algorithm is not supposed to work with complex inputs, set **Complexity** to **Off**.

Step 3: Customize Your Library Using Masking

In this exercise you will modify the convolution filter `my_conv` to use a custom parameter `shape` that specifies what subsection of the convolution to output. To customize this algorithm for your library, place the `my_conv_filter` block under a masked subsystem and define `shape` as a mask parameter.

1. Convert the block to a masked subsystem:

   a. Right-click the `my_conv_filter` block and select **Subsystem & Model Reference** > **Create Subsystem from Selection**.

      The `my_conv_filter` block changes to a subsystem block.

   b. Change the name of the subsystem to `my_conv_filter`.

   c. Right-click the `my_conv_filter` subsystem and select **Mask** > **Create Mask** from the context menu.

      The Mask Editor appears with the **Icon & Ports** tab open.

   d. Enter in the **Icon drawing commands** text box:

      ```
      disp('my_conv');
      port_label('output', 1, 'c');
      port_label('input', 1, 'a');
      port_label('input', 2, 'b');
      ```

   e. Select the **Parameters & Dialog** tab.

   f. Highlight the **Parameters** line item in the Dialog box pane.

   g. Add a popup-type parameter by clicking **Popup** under the **Parameter** list in the **Controls** pane.

      A new parameter will appear in the Dialog box pane.

   h. In the **Property editor** pane, set the **Properties**:

Property	Value
Name	`shape`
Value	`full`
Prompt	`shape`
Type	`popup`

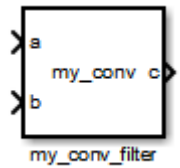
Type options	Open the Type Options Editor and enter:
	
	`full`
	`same`
	`valid`

- Set the **Attributes**, **Dialog**, and **Layout** properties in the **Property editor** pane:

Attributes, Dialog, and Layout Items	Value
Attributes	• Evaluate: Checked • Tunable: Cleared • Read only: Cleared • Hidden: Cleared • Never save: Cleared
Dialog	• Enable: Checked • Visible: Checked • Callback: no entry
Layout	• Item location: Grayed out • Prompt location: Left

- Click **OK**.

Your subsystem should now look like this:



2 Set subsystem properties for code reuse:

   a Right-click the `my_conv_filter` subsystem and select **Block Parameters (Subsystem)** from the context menu.

   b In the subsystem parameters dialog box, select the **Treat as atomic unit** check box.

      The dialog box expands to display new fields.

   c To generate a reusable function, select the Code Generation tab and in the **Function packaging** field, select `Reusable function` from the drop-down menu.

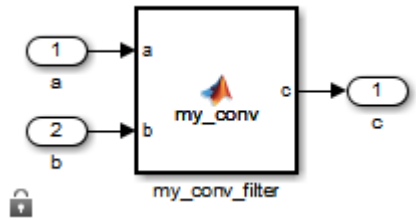
      Note: This is an optional step, required for this example. If you leave the default setting of **Auto**, the code generation software uses an internal rule to determine whether to inline the function or not.

   d Click **OK**.

3 Define the `shape` parameter in the MATLAB Function `my_conv`:

   a Right-click the `my_conv_filter` subsystem and select **Mask** > **Look Under Mask** from the context menu.

      The block diagram under the masked subsystem opens, containing the `my_conv_filter` block:



b Change the names of the port blocks to match the data names as follows:

Change:	To:
`In1`	a
`In2`	b
`Out1`	c

c Double-click the `my_conv_filter` block to open the MATLAB Function Block Editor.

d In the MATLAB Function Block Editor, select **Edit Data**.

e In the Ports and Data Manager, select **Add** > **Data**.

A new data element appears selected, along with its properties dialog.

f Enter the following properties:

Property	What To Specify
Name	Enter `shape`.
Scope	Select **Parameter**.
Tunable	Clear the box.

g Leave **Size**, **Complexity**, and **Type** as inherited (the defaults), as described in "Step 2: Configure Blocks to Inherit Properties You Want to Specialize" on page 39-128.

h Click **Apply**, close the Ports and Data Manager, and return to the MATLAB Function Block Editor.

4 Use the `shape` parameter to determine the size of the convolution to output:

a In the MATLAB Function Block Editor, modify the `my_conv` function to call `conv` with the right shape:

```
function c = my_conv(a, b, shape)
if shape == 1
    c = conv(a, b, 'full');
elseif shape == 2
    c = conv(a, b, 'same');
else
    c = conv(a, b, 'valid');
end
```

b Save your changes and close the MATLAB Function Block Editor.

Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model

In this exercise, you will add specialized instances of the `my_conv_filter` library block to a simple test model.

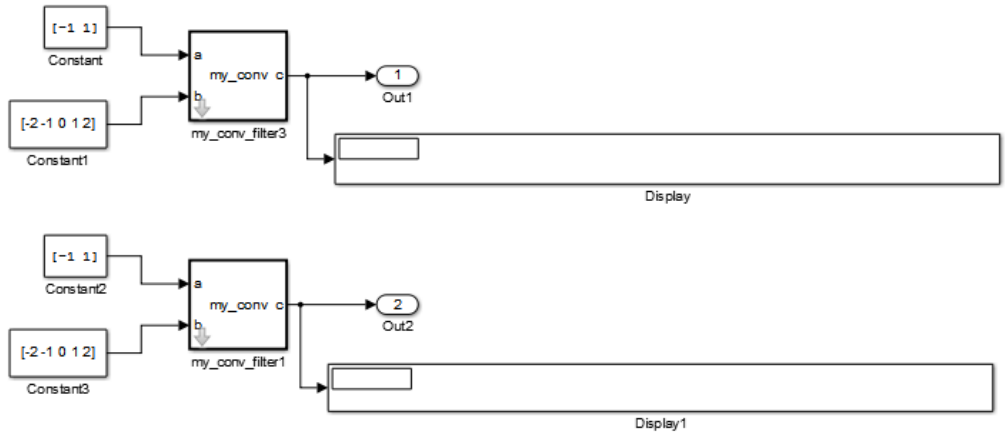
1 Open a new Simulink model.

For purposes of this exercise, set the following configuration parameters for simulation:

Pane	Section	What to Specify
Solver	**Solver options**	• Select **Fixed-Step** for **Type** • Select **discrete (no continuous states)** for **Solver** • Enter **1** for **Fixed-step size**
Data Import/Export	**Save options**	**Structure** for **Format**

2 Drag two instances of the `my_conv_filter` block from the `my_filter_lib` library into the model.

3 Add `Constant`, `Outport`, and `Display` blocks. Your model should look something like this:



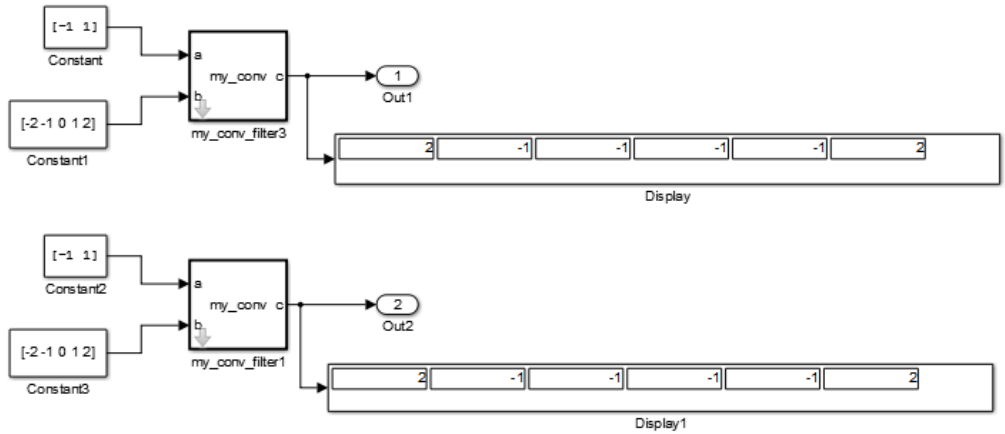
Both library instances share the same size, type, and complexity for inputs `a` and `b` respectively.

4 Double-click each library instance.

The `shape` parameter defaults to **full** for both instances.

5 Simulate the model.

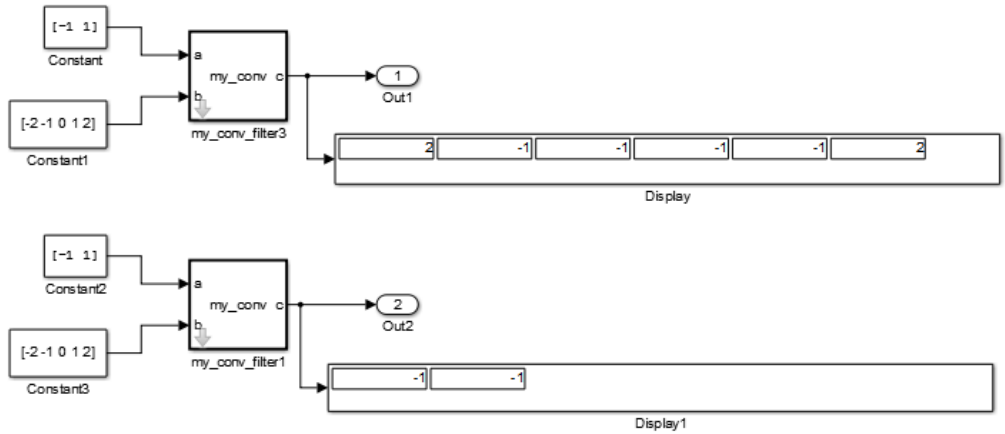
Each library instance outputs the same result, the full 2D convolution:



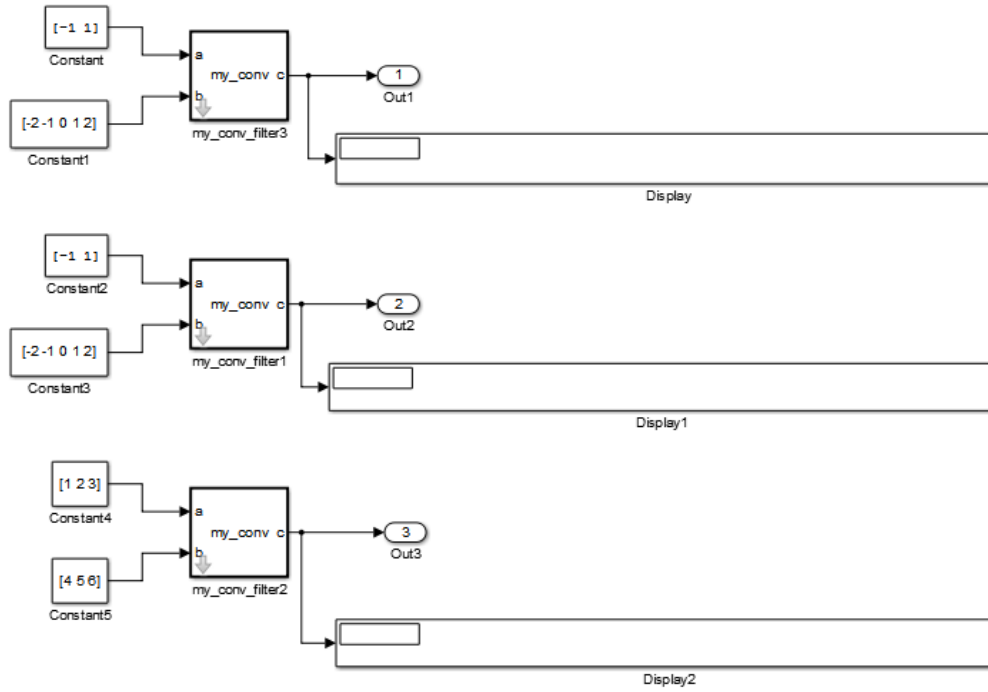
6 Specialize the second instance, `my_conv_filter1` by setting the value of its `shape` parameter to **same**.

7 Now simulate the model again.

This time, the outputs have different sizes: `my_conv_filter3` outputs the full 2D convolution, while `my_conv_filter1` displays the central part of the convolution as a 1-by-2 vector, the same size as `a`:

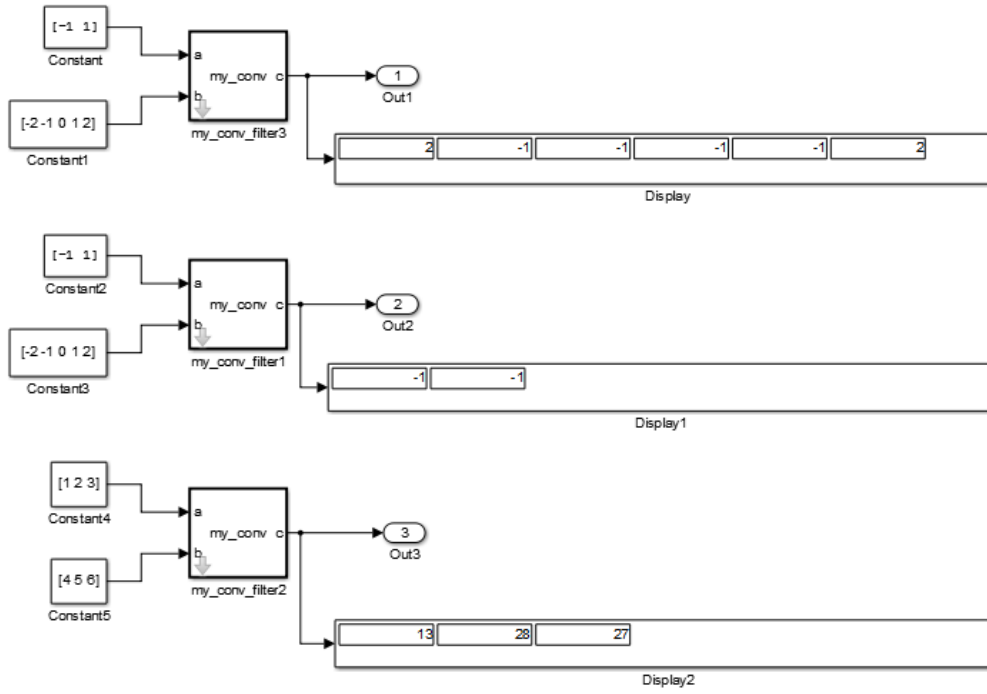


8 Now, add a third instance by copying `my_conv_filter1`. Specialize the new instance, `my_conv_filter2`, so that it does not inherit the same size inputs as the first two instances:



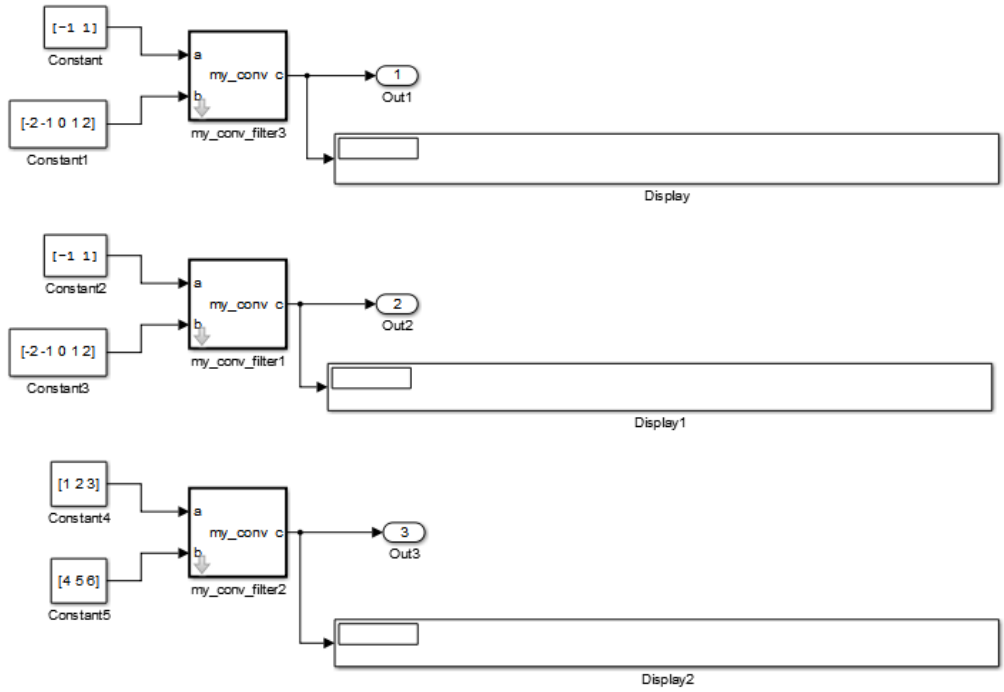
9 Simulate the model again.

This time, `my_conv_filter1` and `my_conv_filter2` each display the central part of the convolution, but the output sizes are different because each matches a different sized input `a`.



Code Reuse with Library Blocks

When instances of `MATLAB Function` library blocks inherit the same properties, they can reuse generated code, as illustrated by an example based on "Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model" on page 39-133:



In this model, the library instances `my_conv_filter` and `my_conv_filter1` inherit the same size, type, and complexity for each respective input. For each instance, input `a` is a 1-by-2 vector and input `b` is a 1-by-5 vector. By comparison, the inputs of `my_conv_filter2` inherit different respective sizes; both are 1-by-3 vectors.

In addition, each library instance has a mask parameter called shape that determines what subsection of the convolution to output. Assume that the value of shape is the same for each instance.

To generate code for this example, follow these steps:

1. Enable code reuse for the library block:
   a. In the library, right-click the `MATLAB Function` block `my_conv_filter` and select **Block Parameters (Subsystem)** from the context menu.
   b. In the Function Block Parameters dialog box, set these parameters:

- Select the **Treat as atomic unit** check box.
- In the **Function packaging** field, select `Reusable function` from the drop-down menu.

2 Configure the model for code generation.

For purposes of this exercise, set the following configuration parameters:

Pane	Section	What to Specify
Code Generation	**Target selection**	Enter **ert.tlc** for `System target file`
Code Generation > **Report**		Select **Create code generation report** check box.

3 Build the model.

If you build this model, the generated C code reuses logic for the `my_conv_filter` and `my_conv_filter1` library instances because they inherit the same input properties:

```
/*
 * Output and update for atomic system:
 *    '<Root>/my_conv_filter'
 *    '<Root>/my_conv_filter1'
 */
void sp_algorithm_tes_my_conv_filter(const real32_T rtu_a[2], const real32_T
  rtu_b[5], rtB_my_conv_filter_sp_algorithm *localB)
{
  int32_T jA;
  int32_T jA_0;
  real32_T s;
  int32_T jC;

  /* MATLAB Function Block: '<S1>/my_conv_filter' */
  /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S4>:1' */
  /* '<S4>:1:4' */
  for (jC = 0; jC < 6; jC++) {
    if (5 < jC + 2) {
      jA = jC - 4;
    } else {
      jA = 0;
```

```
    }

    if (2 < jC + 1) {
      jA_0 = 2;
    } else {
      jA_0 = jC + 1;
    }

    s = 0.0F;
    while (jA + 1 <= jA_0) {
      s += rtu_b[jC - jA] * rtu_a[jA];
      jA++;
    }

    localB->c[jC] = s;
  }

  /* end of MATLAB Function Block: '<S1>/my_conv_filter' */
}
```

However, a separate function is generated for `my_conv_filter2`:

```
/* Output and update for atomic system: '<Root>/my_conv_filter2' */
void sp_algorithm_te_my_conv_filter2(const real_T rtu_a[3], const real_T rtu_b[3],
  rtB_my_conv_filter_sp_algorit_h *localB)
{
  int32_T jA;
  int32_T jA_0;
  real_T s;
  int32_T jC;

  /* MATLAB Function Block: '<S3>/my_conv_filter' */
  /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S6>:1' */
  /* '<S6>:1:4' */
  for (jC = 0; jC < 5; jC++) {
    if (3 < jC + 2) {
      jA = jC - 2;
    } else {
      jA = 0;
    }

    if (3 < jC + 1) {
      jA_0 = 3;
    } else {
      jA_0 = jC + 1;
    }

    s = 0.0;
    while (jA + 1 <= jA_0) {
      s += rtu_b[jC - jA] * rtu_a[jA];
      jA++;
    }

    localB->c[jC] = s;
  }

  /* end of MATLAB Function Block: '<S3>/my_conv_filter' */
}
```

Note: Generating C code for this model requires a Simulink Coder or Embedded Coder license.

Debugging MATLAB Function Library Blocks

You debug `MATLAB Function` library blocks the same way you debug any `MATLAB Function` block. However, when you add a breakpoint in a library block, the breakpoint is shared by all instances. As you continue execution, the debugger stops at the breakpoint in each instance.

Properties You Can Specialize Across Instances of Library Blocks

You can specialize instances of `MATLAB Function` library blocks by allowing them to inherit any of the following properties from Simulink:

Property	Inherits by Default?	How to Specify Inheritance
Type	Yes	Set data type property to **Inherit: Same as Simulink**.
Size	Yes	Set data size property to **-1**.
Complexity	Yes	Set data complexity property to **Inherited**.
Limit range	No	Specify minimum and maximum values as Simulink parameters. For example, if minimum value = `aParam` and maximum value = `aParam` + 3, different instances of a `MATLAB Function` library block can resolve to different `aParam` parameters defined in their parent mask subsystems.
Sampling mode (input)	Yes	`MATLAB Function` block input ports always inherit sampling mode
Data type override mode for fixed-point data	Yes	Set data type override property to **Inherit**.
Sample time (block)	Yes	Set block sample time property to **-1**.

Use Traceability in MATLAB Function Blocks

In this section...
"Extent of Traceability in MATLAB Function Blocks" on page 39-145
"Traceability Requirements" on page 39-145
"Basic Workflow for Using Traceability" on page 39-145
"Tutorial: Using Traceability in a MATLAB Function Block" on page 39-146

Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, `MATLAB Function` blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select this option, the MATLAB source code appears immediately after the associated traceability tag. For more information, see "Include MATLAB Code as Comments in Generated Code" on page 39-149.

For information about how traceability works in Simulink blocks, see "What Is Code Tracing?".

Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (`ERT`) target.

Note: Traceability is not supported for MATLAB files that you call from a `MATLAB Function` block.

Basic Workflow for Using Traceability

The workflow for using traceability is described in "Trace Model Objects to Generated Code". Here are the basic steps:

1. Open the `MATLAB Function` block in your Simulink model.
2. Define your system target file to be an Embedded Real-Time (`ERT`) target.
   a. In the model, select **Simulation > Model Configuration Parameters**.
   b. In the **Code Generation** pane, enter `ert.tlc` for the system target file.
3. Enable traceability options.
   a. In the **Code Generation > Report** pane, select **Create code generation report**.

      This action automatically selects the **Open report automatically** and **Code-to-model** options.
   b. Select **Model-to-code**.

      This action automatically selects all options in the **Traceability Report Contents** section.
4. Generate the source code and header files for your model.
5. Trace a line of code:

To Trace:	Do This:
Line of source code to line of generated code	Right-click in a line in your source code and select **Code Generation > Navigate to Code** from the context menu
Line of generated code to line of source code	Click a hyperlink in the traceability comment in your generated code

To learn how to complete each step in this workflow, see "Tutorial: Using Traceability in a MATLAB Function Block" on page 39-146

Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a `MATLAB Function` block in the `eml_fire` model. Follow these steps:

1. Type `eml_fire` at the MATLAB prompt.
2. In the Simulink model window, double-click the `flame` block to open the MATLAB Function Block Editor.

3. In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.
4. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**.

   Note: Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert`) targets.
5. In the **Code Generation > Report** pane, select the **Create code generation report** option.

   This action automatically selects the **Open report automatically** and **Code-to-model** options.
6. Select the **Model-to-code** option in the **Navigation** section. Then click **Apply**.

   This action automatically selects all options in the **Traceability Report Contents** section.

   Note: For large models that contain over 1000 blocks, disable the **Model-to-code** option to speed up code generation.
7. Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** option. Then click **Apply**.

   Note: Because this example model contains a block with a continuous sample time, you must perform this step before generating code.
8. In the model window, press **Ctrl+B**.

   This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.
9. Click the `eml_fire.c` hyperlink in the report.
10. Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```
for (b_x = 0; b_x < 256; b_x++) {
           /* '<S2>:1:19' */
           /* '<S2>:1:21' */
```

```
yb = loopVar_i + 2;

/* '<S2>:1:22' */
xb = b_x - 1;
```

Note: The line numbers shown above may differ from the numbers that appear in your code generation report.

11 Click the `<S2>:1:19` hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function appears highlighted in the MATLAB Function Block Editor.

12 You can also trace a line in a MATLAB function to a line of generated code. For example, right-click in line 21 of your function and select **Code Generation** > **Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

- “What Is Code Tracing?”

Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a `MATLAB Function` block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select this option, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the `MATLAB Function` block, see "Use Traceability in MATLAB Function Blocks" on page 39-145.

  For examples and information on the location of the comments in the generated code, see "Location of Comments in Generated Code" on page 39-150.
- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

Note: With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see "Including MATLAB Function Help Text in the Function Banner" on page 39-152.

How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a `MATLAB Function` block:

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
        /*  Convert polar to Cartesian */
        /* '<S1>:1:4' x = r * cos(theta); */
        /* '<S1>:1:5' y = r * sin(theta); */
        straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

        /* Outport: '<Root>/y' incorporates:
         *  Inport: '<Root>/r'
         *  Inport: '<Root>/theta'
         *  MATLAB Function Block: '<Root>/straightline'
         */
        straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

MATLAB Code

```
function y = ifstmt(u,v)
```

```
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' if u > v */
        if (MLFcn_U.u > MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:4' y = v + 10; */
          MLFcn_Y.y = MLFcn_U.v + 10.0;
        } else if (MLFcn_U.u == MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:5' elseif u == v */
          /* '<S1>:1:6' y = u * 2; */
          MLFcn_Y.y = MLFcn_U.u * 2.0;
        } else {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:7' else */
          /* '<S1>:1:8' y = v - 10; */
          MLFcn_Y.y = MLFcn_U.v - 10.0;
```

For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

MATLAB Code

```
function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
    y = y + 1;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' y = 0; */
```

```
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
  /* '<S1>:1:6' y = y + 1; */
  rtb_y++;
```

While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

Including MATLAB Function Help Text in the Function Banner

You can include the function help text in the function banner of the code generated for a `MATLAB Function` block. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select **MATLAB function help text** and click **Apply**.

Note: If the function is inlined, the function help text is also inlined. Therefore, the help text for inlined functions appears in the function body in the generated code even when this option is selected.

Limitations of MATLAB Source Code as Comments

The `MATLAB Function` block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow `Truth Table` blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

Integrate C Code Using the MATLAB Function Block

In this section...
"Call C Code from a Simulink model" on page 39-154
"Control Imported Bus and Enumeration Type Definitions" on page 39-156

Call C Code from a Simulink model

You can call external C code from a Simulink model using a `MATLAB Function` block and the `coder.ceval` command. Follow these high-level steps:

1. Start with existing C code consisting of the source (`.c`) and header (`.h`) files.
2. In the `MATLAB Function` block, enter the MATLAB code that calls the C code. Use the command `coder.ceval`.
3. Specify the C source and header files for simulation in the **Simulation Target** pane of the Configuration Parameters dialog box.

   Include the header file using double quotations, such as `#include "program.h"`.
4. If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane of the Configuration Parameters dialog box, in the **Include Directories** text box.
5. Test your Simulink model and ensure it functions correctly.
6. To use the same source and header files for code generation, click **Use the same custom code settings as Simulation Target** in the **Code Generation > Custom Code** pane.

   You can also specify different source and header files.

If you have a Simulink Coder license, you can generate code for targets using this method.

Call the doubleIt Program Using a MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a `MATLAB Function` block.

1. Create the source file `doubleIt.c` in your current working folder.

```
/* doubleIt, a simple program that returns double the input */

#include "doubleIt.h"

double doubleIt(double u)
{
     return(u*2.0);
}
```

2 Create the header file `doubleIt.h` in your current working folder.

```
double doubleIt(double u);
```

3 Create a new Simulink model.

4 Add a `MATLAB Function` block to the model and double-click the block to open the editor.

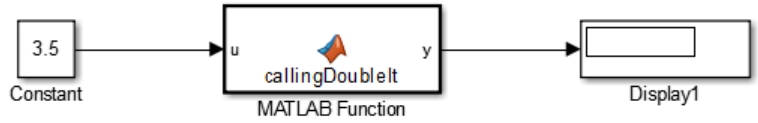
5 Enter code that calls the `doubleIt` program:

```
function y = callingDoubleIt(u)
%#codegen

y = 0.0;
y = coder.ceval('doubleIt',u);
```

6 Connect a Constant block having a value of `3.5` to the input port of the `MATLAB Function` block.

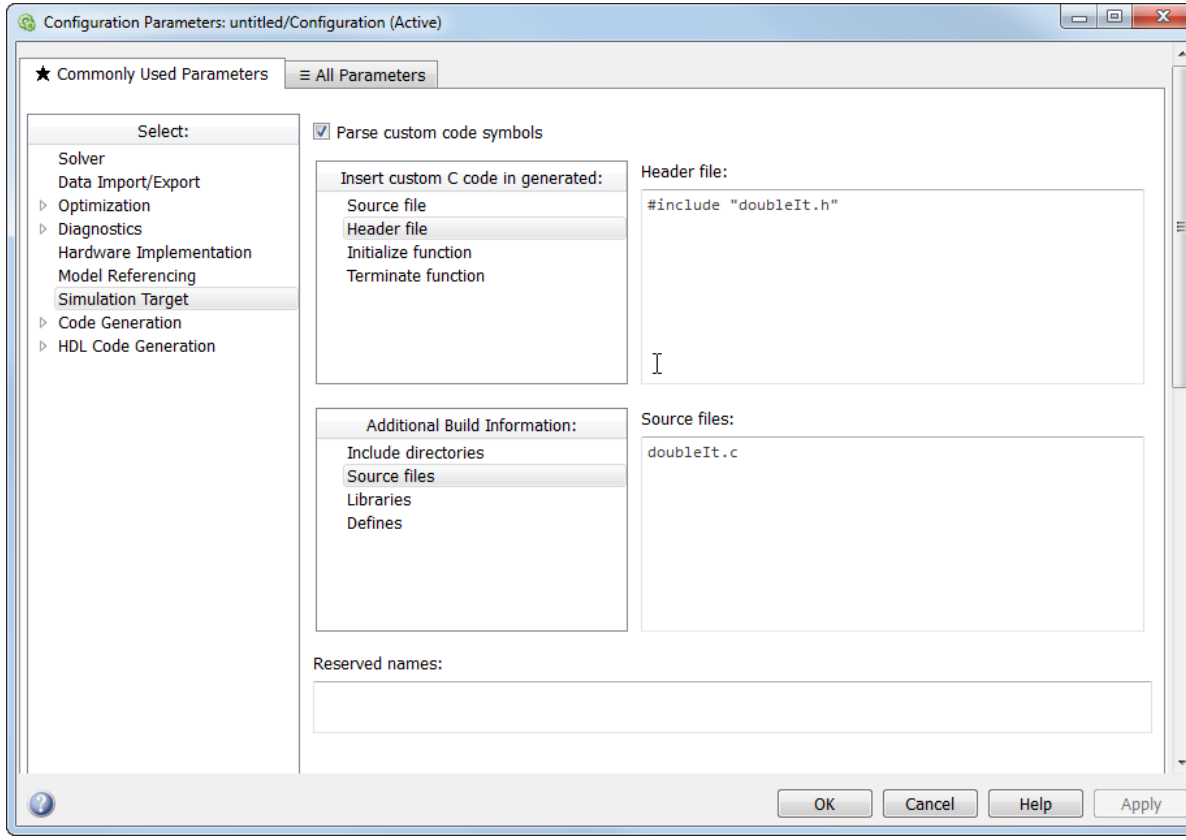
7 Connect a Display block to the output port.



8 In the Configuration Parameters dialog box, open the **Simulation Target** pane.

9 In the **Insert custom C code in generated** section, select **Header file** from the list, and enter `#include "doubleIt.h"` in the **Header file** text box.

10 In the **Include list of additional** section, select **Source files** from the list, enter `doubleIt.c` in the **Source files** text box, and click **OK**.



11 Simulate the model.

The value 7 appears in the Display block.

Control Imported Bus and Enumeration Type Definitions

This procedure applies to simulation only.

Simulink generates code for `MATLAB Function` blocks and Stateflow to simulate the model. When you call external C code using `MATLAB Function` blocks or Stateflow, you can control the type definitions for imported buses and enumerations in model simulation.

Simulink can generate type definitions, or you can supply a header file containing the type definitions. You control this behavior using the **Generate typedefs for imported bus and enumeration types** check box in the **All Parameters** pane of the Configuration Parameters dialog box.

To include a custom header file defining the enumeration and bus types:

1. Clear the **Generate typedefs for imported bus and enumeration types** check box.
2. List the header file in the **Simulation Target** pane, in the **Header file** text box.

To configure Simulink to automatically generate type definitions:

1. Select the **Generate typedefs for imported bus and enumeration types** check box.
2. Do not list a header file that corresponds to the buses or enumerations.

Enhance Code Readability for MATLAB Function Blocks

In this section...

"Requirements for Using Readability Optimizations" on page 39-158

"Converting If-Elseif-Else Code to Switch-Case Statements" on page 39-158

"Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements" on page 39-160

Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (`ert`) target.

Note: These optimizations do not apply to MATLAB files that you call from the `MATLAB Function` block.

For more information, see "Select an ERT System Target File" and "Control Code Style" in the Embedded Coder documentation.

Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a `MATLAB Function` block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the `MATLAB Function` block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	"Verifying the Contents of the Block" on page 39-162
2	Enable the conversion.	"Enabling the Conversion" on page 39-163
3	Generate code for your model.	"Generating Code for Your Model" on page 39-164

Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
`MATLAB Function` block	Must have two or more *unique* conditions, in addition to a default. For more information, see "How the Conversion Handles Duplicate Conditions" on page 39-160.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS. **Note:** You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression, not a compound statement.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Cannot have any side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a `MATLAB Function` block has duplicate conditions, the conversion preserves only the first condition. The generated code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, no conversion occurs and the generated code contains all instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

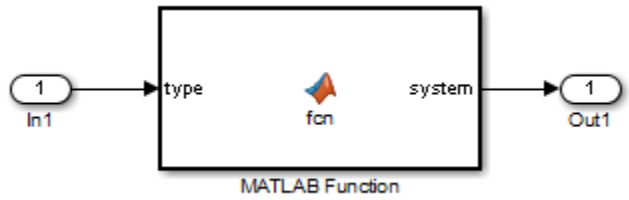
Example of Generated Code	Code After Conversion

`if (x == 1) {`
`  block1`
`} else if (x == 2) {`
`  block2`
`} else if (x == 1) {  // duplicate`
`  block3`
`} else if (x == 3) {`
`  block4`
`} else if (x == 1) {  // duplicate`
`  block5`
`} else {`
`  block6`
`}`
	`switch (x) {`
	`  case 1:`
	`  block1; break;`
	`  case 2:`
	`  block2; break;`
	`  case 3:`
	`  block4; break;`
	`  default:`
	`  block6; break;`
	`}`

`if (x == 1) {`
`  block1`
`} else if (x == 1) {  // duplicate`
`  block2`
`} else {`
`  block3`
`}`
	No change, because only one unique condition exists

Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a `MATLAB Function` block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define. (For more information, see “Define Enumerated Data Types for MATLAB Function Blocks” on page 39-105.)



The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
  enumeration
    P(0)
    I(1)
    PD(2)
    PI(3)
    PID(4)
    UNKNOWN(10)
  end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_eml_blocks_U.In1 == P) {
```

```
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
}
```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

Note: By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see "Use Traceability in MATLAB Function Blocks" on page 39-145.

Verifying the Contents of the Block

Check that the block follows all the rules in "Rules for Conversion" on page 39-159.

Construct	How the Construct Follows the Rules
MATLAB `Function` block	Five unique conditions exist, in addition to the default: • `(type == Controller.P)`

Construct	How the Construct Follows the Rules
	• `(type == Controller.I)` • `(type == Controller.PD)` • `(type == Controller.PI)` • `(type == Controller.PID)`
Each condition	Each condition: • Tests equality • Uses the same input for the LHS
Each LHS	Each LHS: • Contains a single variable • Is the input to the block and therefore not a constant • Is of enumerated type `Controller`, which you define in `Controller.m` on the MATLAB path • Has no side effects on simulation
Each RHS	Each RHS: • Is an enumerated value and therefore a constant • Is of enumerated type `Controller`

Enabling the Conversion

1. Open the Configuration Parameters dialog box.
2. In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

   This step specifies an embedded real-time target for your model.
3. In the **Code Generation** > **Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- All `MATLAB Function` blocks in a model
- MATLAB functions in all Stateflow charts of that model

- Flow charts in all Stateflow charts of that model

For more information, see "Enhance Readability of Code for Flow Charts" in the Embedded Coder documentation.

Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the `MATLAB Function` block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
 case P:
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
  break;

 case I:
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
  break;

 case PD:
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
  break;

 case PI:
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
  break;

 case PID:
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
  break;

 default:
```

```
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
  break;
}
```

The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

Control Run-Time Checks

In this section...
"Types of Run-Time Checks" on page 39-166
"When to Disable Run-Time Checks" on page 39-166
"How to Disable Run-Time Checks" on page 39-167

Types of Run-Time Checks

In simulation, the code generated for your `MATLAB Function` block includes the following run-time checks:

- Memory integrity checks

  These checks detect violations of memory integrity in code generated for `MATLAB Function` blocks and stop execution with a diagnostic message.

  Caution For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

- Responsiveness checks in code generated for `MATLAB Function` blocks

  These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

  Caution For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

Consider disabling:	Only if:
Memory integrity checks	You are sure that your code is safe and that all array bounds and dimension checking is unnecessary.
Responsiveness checks	You are sure that you will not need to stop execution of your application using Ctrl+C.

How to Disable Run-Time Checks

`MATLAB Function` blocks enable run-time checks by default, but you can disable them explicitly for all `MATLAB Function` blocks in your Simulink model. Follow these steps:

1. Open your `MATLAB Function` block.
2. In the MATLAB Function Block Editor, select **Simulation Target**.
3. In the **All Parameters** tab of the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

Track Object Using MATLAB Code

In this section...
“Learning Objectives” on page 39-168
“Tutorial Prerequisites” on page 39-168
“Example: The Kalman Filter” on page 39-169
“Files for the Tutorial” on page 39-172
“Tutorial Steps” on page 39-173
“Best Practices Used in This Tutorial” on page 39-191
“Key Points to Remember” on page 39-191

Learning Objectives

In this tutorial, you will learn how to:

- Use the `MATLAB Function` block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

  This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.
- Use `coder.extrinsic` to call MATLAB code from a `MATLAB Function` block.

  This capability allows you to do rapid prototyping. You can call existing MATLAB code from Simulink without having to make this code suitable for code generation.
- Check that existing MATLAB code is suitable for code generation before generating code.

  You must prepare your code before generating code.
- Specify variable-size inputs when generating code.

Tutorial Prerequisites

- “What You Need to Know” on page 39-169
- “Required Products” on page 39-169

What You Need to Know

To complete this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create and simulate a basic Simulink model.

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- C compiler

For a list of supported compilers, see `http://www.mathworks.com/support/compilers/current_release/`.

You must set up the C compiler before generating C code. See "Setting Up Your C Compiler" on page 39-174.

For instructions on installing MathWorks products, see the MATLAB installation documentation for your platform. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window.

Example: The Kalman Filter

- "Description" on page 39-169
- "Algorithm" on page 39-170
- "Filtering Process" on page 39-171
- "Reference" on page 39-172

Description

This section describes the example used by the tutorial. You do not have to be familiar with the algorithm to complete the tutorial.

The example for this tutorial uses a Kalman filter to estimate the position of an object moving in a two-dimensional space from a series of noisy inputs based on past positions.

The position vector has two components, `x` and `y`, indicating its horizontal and vertical coordinates.

Kalman filters have a wide range of applications, including control, signal and image processing; radar and sonar; and financial modeling. They are recursive filters that estimate the state of a linear dynamic system from a series of incomplete or noisy measurements. The Kalman filter algorithm relies on the state-space representation of filters and uses a set of variables stored in the state vector to characterize completely the behavior of the system. It updates the state vector linearly and recursively using a state transition matrix and a process noise estimate.

Algorithm

This section describes the algorithm of the Kalman filter and is implemented in the MATLAB version of the filter supplied with this tutorial.

The algorithm predicts the position of a moving object based on its past positions using a Kalman filter estimator. It estimates the present position by updating the Kalman state vector, which includes the position (*x* and *y*), velocity (*Vx* and *Vy*), and acceleration (*Ax* and *Ay*) of the moving object. The Kalman state vector, `x_est`, is a persistent variable.

```
% Initial conditions
persistent x_est p_est
if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
```

`x_est` is initialized to an empty `6x1` column vector and updated each time the filter is used.

The Kalman filter uses the laws of motion to estimate the new state:

$$X = X_0 + Vx.dt$$
$$Y = Y_0 + Vy.dt$$
$$Vx = Vx_0 + Ax.dt$$
$$Vy = Vy_0 + Ay.dt$$

These laws of motion are captured in the state transition matrix `A`, which is a matrix that contains the coefficient values of `x`, `y`, V_x, V_y, A_x, and A_y.

```
% Initialize state transition matrix
dt=1;
A=[ 1 0 dt 0 0 0;...
    0 1 0 dt 0 0;...
    0 0 1 0 dt 0;...
    0 0 0 1 0 dt;...
    0 0 0 0 1 0 ;...
    0 0 0 0 0 1 ];
```

Filtering Process

The filtering process has two phases:

- Predicted state and covariance

  The Kalman filter uses the previously estimated state, `x_est`, to predict the current state, `x_prd`. The predicted state and covariance are calculated in:

  ```
  % Predicted state and covariance
  x_prd = A * x_est;
  p_prd = A * p_est * A' + Q;
  ```

- Estimation

  The filter also uses the current measurement, `z`, and the predicted state, `x_prd`, to estimate a more accurate approximation of the current state. The estimated state and covariance are calculated in:

  ```
  % Measurement matrix
  H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
  Q = eye(6);
  R = 1000 * eye(2);

  % Estimation
  S = H * p_prd' * H' + R;
  B = H * p_prd';
  klm_gain = (S \ B)';

  % Estimated state and covariance
  x_est = x_prd + klm_gain * (z - H * x_prd);
  p_est = p_prd - klm_gain * H * p_prd;

  % Compute the estimated measurements
  y = H * x_est;
  ```

Reference

Haykin, Simon. *Adaptive Filter Theory*. Upper Saddle River, NJ: Prentice-Hall, Inc., 1996.

Files for the Tutorial

- "About the Tutorial Files" on page 39-172
- "Location of Files" on page 39-172
- "Names and Descriptions of Files" on page 39-172

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- Example MATLAB code files for each step of the tutorial.

  Throughout this tutorial, you work with Simulink models that call MATLAB files containing a Kalman filter algorithm.
- A MAT-file that contains example input data.
- A MATLAB file for plotting.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\kalman`. To run the tutorial, you must copy these files to a local folder. For instructions, see "Copying Files Locally" on page 39-174.

Names and Descriptions of Files

Type	Name	Description
MATLAB function files	`ex_kalman01`	Baseline MATLAB implementation of a scalar Kalman filter.
	`ex_kalman02`	Version of the original algorithm suitable for code generation.

Type	Name	Description
	`ex_kalman03`	Version of Kalman filter suitable for code generation and for use with frame-based and packet-based inputs.
	`ex_kalman04`	Disabled inlining for code generation.
Simulink model files	`ex_kalman00`	Simulink model without a `MATLAB Function` block.
	`ex_kalman11`	Complete Simulink model with a `MATLAB Function` block for scalar Kalman filter.
	`ex_kalman22`	Simulink model with a `MATLAB Function` block for a Kalman filter that accepts fixed-size (frame-based) inputs.
	`ex_kalman33`	Simulink model with a `MATLAB Function` block for a Kalman filter that accepts variable-size (packet-based) inputs.
	`ex_kalman44`	Simulink model to call `ex_kalman04.m`, which has inlining disabled.
MATLAB data file	`position`	Contains the input data used by the algorithm.
Plot files	`plot_trajectory`	Plots the trajectory of the object and the Kalman filter estimated position.

Tutorial Steps

- "About the ex_kalman00 Model" on page 39-175
- "Adding a MATLAB Function Block to Your Model" on page 39-176
- "Checking the ex_kalman11 Model" on page 39-178
- "Simulating the ex_kalman11 Model" on page 39-179
- "Modifying the Filter to Accept a Fixed-Size Input" on page 39-181
- "Using the Filter to Accept a Variable-Size Input" on page 39-185
- "Debugging the MATLAB Function Block" on page 39-188

- "Generating C Code" on page 39-189

Copying Files Locally

Copy the tutorial files to a local working folder:

1. Create a local *solutions* folder, for example, `c:\simulink\kalman\solutions`.
2. Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

   ```
   cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
   ```
3. Copy the contents of the `kalman` subfolder to your local *solutions* folder, specifying the full path name of the *solutions* folder:

   ```
   copyfile('kalman', 'solutions')
   ```

   For example:

   ```
   copyfile('kalman', 'c:\simulink\kalman\solutions')
   ```

   Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task in the tutorial, you can view the solutions to see how the code should look.
4. Create a local *work* folder, for example, `c:\simulink\kalman\work`.
5. Copy the following files from your *solutions* folder to your *work* folder.

   - `ex_kalman01`
   - `ex_kalman00`
   - `position`
   - `plot_trajectory`

   Your *work* folder now contains all the files that you need to get started with the tutorial.

Setting Up Your C Compiler

Building your `MATLAB Function` block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See "Change Default Compiler".

About the ex_kalman00 Model

First, examine the `ex_kalman00` model supplied with the tutorial to understand the problem that you are trying to solve using the Kalman filter.

1. Open the `ex_kalman00` model in Simulink:

   a. Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

      ```
      cd work
      ```
      where *`work`* is the full path name of the folder containing your files.

   b. At the MATLAB command line, enter:

      ```
      ex_kalman00
      ```

      This model is an incomplete model to demonstrate how to integrate MATLAB code with Simulink. The complete model is `ex_kalman11`, which is also supplied with this tutorial.

InitFcn Model Callback Function

The model uses this callback function to:

- Load position data from a MAT-file.
- Set up data used by the Index generator block, which provides the second input to the `Selector` block.

To view this callback:

1. Select **File** > **Model Properties** > **Model Properties**.
2. Select the **Callbacks** tab.
3. Select `InitFcn` in the **Model callbacks** pane.

   The callback appears.

   ```
   load position.mat;
   [R,C]=size(position);
   idx=(1:C)';
   t=idx-1;
   ```

Source Blocks

The model uses two `Source` blocks to provide position data and a scalar index to a `Selector` block.

Selector Block

The model uses a `Selector` block that selects elements of its input signal and generates an output signal based on its index input and its **Index Option** settings. By changing the configuration of this block, you can generate different size signals.

To view the `Selector` block settings, double-click the `Selector` block to view the function block parameters.

In this model, the **Index Option** for the first port is `Select all` and for the second port is `Index vector (port)`. Because the input is a `2 x 310` position matrix, and the index data increments from `1` to `310`, the `Selector` block simply outputs one `2x1` output at each sample time.

MATLAB Function Block

The model uses a `MATLAB Function` block to plot the trajectory of the object and the Kalman filter estimated position. This function:

- First declares the `figure`, `hold`, and `plot_trajectory` functions as extrinsic because these MATLAB visualization functions are not supported for code generation. When you call an unsupported MATLAB function, you must declare it to be extrinsic so MATLAB can execute it, but does not try to generate code for it.
- Creates a figure window and holds it for the duration of the simulation. Otherwise a new figure window appears for each sample time.
- Calls the `plot_trajectory` function, which plots the trajectory of the object and the Kalman filter estimated position.

Simulation Stop Time

The simulation stop time is `309`, because the input to the filter is a vector containing `310` elements and Simulink uses zero-based indexing.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman11` in your *`solutions`* subfolder to see the modified model.

For the purposes of this tutorial, you add the `MATLAB Function` block to the `ex_kalman00.mdl` model supplied with the tutorial. You would have to develop your own test bench starting with an empty Simulink model.

Adding the MATLAB Function Block

To add a `MATLAB Function` block to the `ex_kalman00` model:

1. Open `ex_kalman00` in Simulink.

   ```
   ex_kalman00
   ```

2. Add a `MATLAB Function` block to the model:

   a. At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.

   b. From the list of Simulink libraries, select the `User-Defined Functions` library.

   c. Click the `MATLAB Function` block and drag it into the `ex_kalman00` model. Place the block just above the red text annotation that reads `Place MATLAB Function Block here.`

   d. Delete the red text annotations from the model.

   e. Save the model in the current folder as `ex_kalman11`.

Calling Your MATLAB Code from the MATLAB Function Block

To call your MATLAB code from the `MATLAB Function` block:

1. Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.
2. Delete the default code displayed in the editor.
3. Copy the following code to the `MATLAB Function` block.

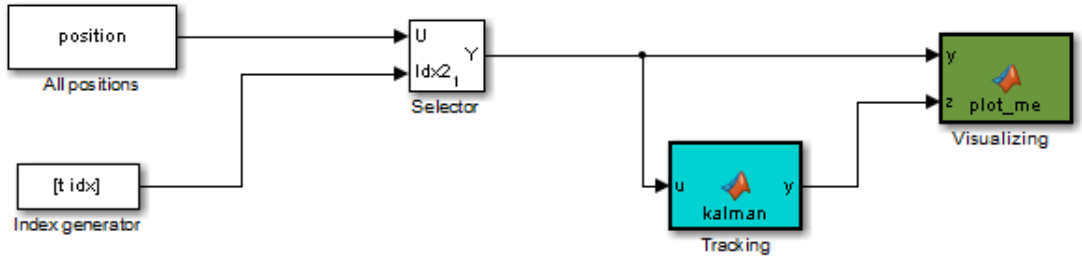
   ```
   function y = kalman(u)
   %#codegen

   y = ex_kalman01(u);
   ```

4. Save the model.

Connecting the MATLAB Function Block Input and Output

1. Connect the `MATLAB Function` block input and output so that your model looks like this.



2 Save the model.

Checking the ex_kalman11 Model

To check the model:

1 In the Simulink model window, select **Simulation > Update Diagram**.

Simulink checks the model and generates a warning telling you to add the `%#codegen` compilation directive to the `ex_kalman01` file. Adding this directive indicates that the file is intended for code generation and turns on code generation error checking.

2 Open `ex_kalman01` file and add the `%#codegen` compilation directive after the function declaration.

```
function y = ex_kalman01(z)  %#codegen
```

3 Modify the function name to `ex_kalman02` and save the file as `ex_kalman02.m`.

4 Modify the model to call `ex_kalman02` by updating the code in the `MATLAB Function` block.

```
function y = kalman(u)
%#codegen

y = ex_kalman02(u);
```

5 Save the model and update diagram again.

This time the model updates successfully.

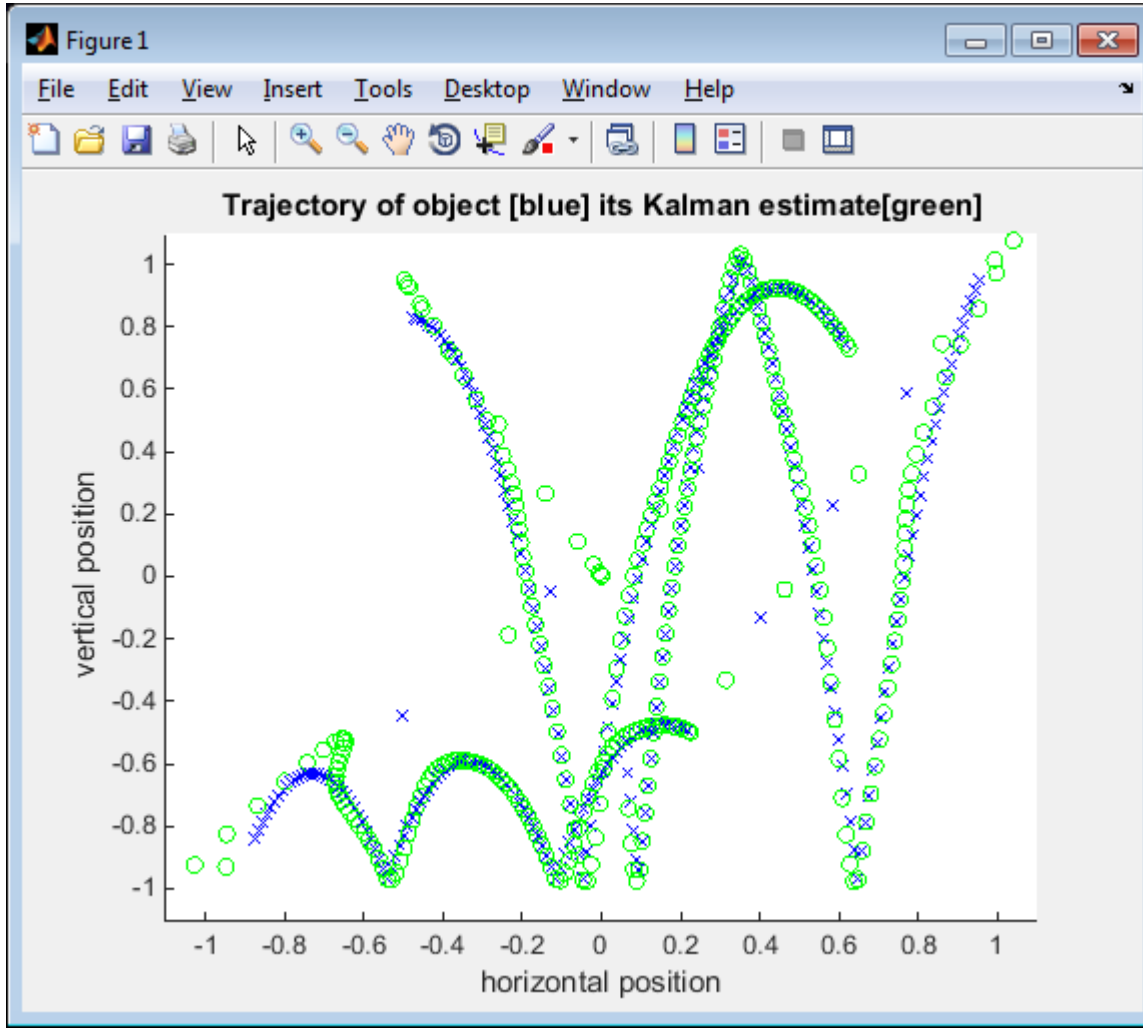
You are now ready to simulate your model, as described in “Simulating the ex_kalman11 Model” on page 39-179.

Simulating the ex_kalman11 Model

To simulate the model:

1. In the Simulink model window, select **Simulation > Run**.

   As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green. Initially, you see that it takes a short time for the estimated position to converge with the actual position of the object. Then three sudden shifts in position occur—each time the Kalman filter readjusts and tracks the object after a few iterations.



2 The simulation stops.

You have proved that your MATLAB algorithm works in Simulink. You are now ready to modify the filter to accept a fixed-size input, as described in “Modifying the Filter to Accept a Fixed-Size Input” on page 39-181.

Modifying the Filter to Accept a Fixed-Size Input

The filter you have worked on so far in this tutorial uses a simple batch process that accepts one input at a time, so you must call the function repeatedly for each input. In this part of the tutorial, you learn how to modify the algorithm to accept a fixed-sized input, which makes the algorithm suitable for frame-based processing. You then modify the model to provide the input as fixed-size frames of data and call the filter passing in the data one frame at a time.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `ex_kalman03.m` in your *`solutions`* subfolder to see the modified algorithm.

You can now modify the algorithm to process a vector containing more than one input. You need to find the length of the vector and call the filter code for each element in the vector in turn. You do this by calling the filter algorithm in a `for` loop.

1. Open `ex_kalman02.m` in the MATLAB Editor. At the MATLAB command line, enter:

   ```
   edit ex_kalman02.m
   ```

2. Add a `for` loop around the filter code.

   a. Before the comment:

   ```
   % Predicted state and covariance
   ```

   insert:

   ```
   for i=1:size(z,2)
   ```

   b. After:

   ```
   % Compute the estimated measurements
   y = H * x_est;
   ```

   insert:

   ```
   end
   ```

   c. Select the code between the `for` statement and the end statement, right-click to open the context menu and select **Smart Indent** to indent the code.

   Your filter code should now look like this:

```
for i=1:size(z,2)
  % Predicted state and covariance
  x_prd = A * x_est;
  p_prd = A * p_est * A' + Q;

  % Estimation
  S = H * p_prd' * H' + R;
  B = H * p_prd';
  klm_gain = (S \ B)';

  % Estimated state and covariance
  x_est = x_prd + klm_gain * (z - H * x_prd);
  p_est = p_prd - klm_gain * H * p_prd;

  % Compute the estimated measurements
  y = H * x_est;
end
```

3 Modify the line that calculates the estimated state and covariance to use the `i`th element of input `z`.

Change:

```
x_est = x_prd + klm_gain * (z - H * x_prd);
```

to:

```
x_est = x_prd + klm_gain * (z(1:2,i) - H * x_prd);
```

4 Modify the line that computes the estimated measurements to append the result to the `i`th element of the output `y`.

Change:

```
y = H * x_est;
```

to:

```
y(:,i) = H * x_est;
```

The code analyzer message indicator in the top right turns orange to indicate that the code analyzer has detected warnings. The code analyzer underlines the offending code in orange and places a orange marker to the right.

5 Move your pointer over the orange marker to view the error information.

The code analyzer detects that `y` must be fully defined before sub-scripting it and that you cannot grow variables through indexing in generated code.

6 To address this warning, preallocate memory for the output `y`, which is the same size as the input `z`. Add this code before the `for` loop.

```
% Pre-allocate output signal:
y=zeros(size(z));
```

The orange marker disappears and the code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

Why Preallocate the Outputs?

You must preallocate outputs here because the code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See "Preallocating Memory".

7 Change the function name to `ex_kalman03` and save the file as `ex_kalman03.m` in the current folder.

You are ready to begin the next task in the tutorial, "Modifying Your Model to Call the Updated Algorithm" on page 39-183.

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman22.mdl` in your *`solutions`* subfolder to see the modified model.

Next, update your model to provide the input as fixed-size frames of data and call `ex_kalman03` passing in the data one frame at a time.

1 Open `ex_kalman11` model in Simulink.

```
ex_kalman11
```

2 Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.

3 Replace the code that calls `ex_kalman02` with a call to `ex_kalman03`.

```
function y = kalman(u)
```

```
%#codegen

y = ex_kalman03(u);
```

4 Close the editor.

5 Modify the `InitFcn` callback:

   a Select **File** > **Model Properties** > **Model Properties**.

      The Model Properties dialog box opens.

   b In this dialog box, select the **Callbacks** tab.

   c Select `InitFcn` in the **Model callbacks** pane.

   d Replace the existing callback with:

```
load position.mat;
[R,C]=size(position);
FRAME_SIZE=5;
idx=(1:FRAME_SIZE:C)';
LEN=length(idx);
t=(1:LEN)'-1;
```

      This callback sets the frame size to `5`, and the index to increment by `5`.

   e Click **Apply** and close the Model Properties dialog box.

6 Update the `Selector` block to use the correct indices.

   a Double-click the `Selector` block to view the function block parameters.

      The Function Block Parameters dialog box opens.

   b Set the second **Index Option** to `Starting index (port)`.

   c Set the **Output Size** for the second input to `FRAME_SIZE`, click **Apply** and close the dialog box.

   Now, the **Index Option** for the first port is `Select all` and for the second port is `Starting index (port)`. Because the index increments by `5` each sample time, and the output size is `5`, the `Selector` block outputs a `2x5` output at each sample time.

7 Change the model simulation stop time to `61`. Now the frame size is `5`, so the simulation completes in a fifth of the sample times.

   a In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.

b In the left pane of the Configuration Parameters dialog box, select **Solver**.

c In the right pane, set **Stop time** to `61`.

d Click **Apply** and close the dialog box.

8 Save the model as `ex_kalman22.mdl`.

Testing Your Modified Algorithm

To simulate the model:

1 In the Simulink model window, select **Simulation** > **Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before when you used the batch filter.

2 The simulation stops.

You have proved that your algorithm accepts a fixed-size signal. You are now ready for the next task, "Using the Filter to Accept a Variable-Size Input" on page 39-185.

Using the Filter to Accept a Variable-Size Input

In this part of the tutorial, you learn how to specify variable-size data in your Simulink model. Then you test your Kalman filter algorithm with variable-size inputs and see that the algorithm is suitable for processing packets of data of varying size. For more information on using variable-size data in Simulink, see "Variable-Size Signal Basics" on page 64-2.

Updating the Model to Use Variable-Size Inputs

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman33.mdl` in your *`solutions`* subfolder to see the modified model.

1 Open `ex_kalman22.mdl` in Simulink.

```
ex_kalman22
```

2 Modify the `InitFcn` callback:

a Select **File** > **Model Properties** > **Model Properties**.

The Model Properties dialog box opens.

b Select the **Callbacks** tab.

c Select `InitFcn` in the **Model callbacks** pane.

d Replace the existing callback with:

```
load position.mat;
idx=[ 1 1 ;2 3 ;4 6 ;7 10 ;11 15 ;16 30 ;
     31 70 ;71 100 ;101 200 ;201 250 ;251 310];
LEN=length(idx);
t=(0:1:LEN-1)';
```

This callback sets up indexing to generate eleven different size inputs. It specifies the start and end indices for each sample time. The first sample time uses only the first element, the second sample time uses the second and third elements, and so on. The largest sample, `101` to `200`, contains 100 elements.

e Click **Apply** and close the **Model Properties** dialog box.

3 Update the `Selector` block to use the correct indices.

a Double-click the `Selector` block to view the function block parameters.

The Function Block Parameters dialog box opens.

b Set the second **Index Option** to `Starting and ending indices (port)`, then click **Apply** and close the dialog box.

This setting means that the input to the index port specifies the start and end indices for the input at each sample time. Because the index input specifies different starting and ending indices at each sample time, the `Selector` block outputs a variable-size signal as the simulation progresses.

4 Use the Ports and Data Manager to set the `MATLAB Function` input `x` and output `y` as variable-size data.

a Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.

b From the editor menu, select **Edit Data**.

c In the Ports and Data Manager left pane, select the input `u`.

The Ports and Data Manager displays information about `u` in the right pane.

d On the **General** tab, select the **Variable size** check box and click **Apply**.

e In the left pane, select the output `y`.

f On the **General** tab:

i Set the **Size** of `y` to `[2 100]` to specify a 2-D matrix where the upper bounds are `2` for the first dimension and `100` for the second, which is the maximum size input specified in the `InitFcn` callback.

ii Select the **Variable size** check box.

iii Click **Apply**.

g Close the Ports and Data Manager.

5 Now do the same for the other `MATLAB Function` block. Use the Ports and Data Manager to set the Visualizing block inputs `y` and `z` as variable-size data.

a Double-click the Visualizing block to open the MATLAB Function Block Editor.

b From the editor menu, select **Edit Data**.

c In the Ports and Data Manager left pane, select the input `y`.

d On the **General** tab, select the **Variable size** check box and click **Apply**.

e In the left pane, select the input `z`.

f On the **General** tab, select the **Variable size** check box and click **Apply**.

g Close the Ports and Data Manager.

6 Change the model simulation stop time to `10`. This time, the filter processes one of the eleven different size inputs each sample time.

7 Save the model as `ex_kalman33.mdl`.

Testing Your Modified Model

To simulate the model:

1 In the Simulink model window, select **Simulation** > **Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before.

Note that the signal lines between the `Selector` block and the Tracking and Visualization blocks change to show that these signals are variable-size.

2 The simulation stops.

You have successfully created an algorithm that accepts variable-size inputs. Next, you learn how to debug your `MATLAB Function` block, as described in "Debugging the MATLAB Function Block" on page 39-188.

Debugging the MATLAB Function Block

You can debug your `MATLAB Function` block just like you can debug a function in MATLAB.

1. Double-click the `MATLAB Function` block that calls the Kalman filter to open the MATLAB Function Block Editor.
2. In the editor, click the dash (-) character in the left margin of the line:

   ```
   y = kalman03(u);
   ```

   A small red ball appears in the margin of this line, indicating that you have set a breakpoint.
3. In the Simulink model window, select **Simulation** > **Run**.

   The simulation pauses when execution reaches the breakpoint and a small green arrow appears in the left margin.
4. Place the pointer over the variable `u`.

   The value of `u` appears adjacent to the pointer.
5. From the MATLAB Function Block Editor menu, select **Step In**.

   The `kalman03.m` file opens in the editor and you can now step through this code using **Step**, **Step In**, and **Step Out**.
6. Select **Step Out**.

   The `kalman03.m` file closes and the `MATLAB Function` block code reappears in the editor.
7. Place the pointer over the output variable `y`.

   You can now see the value of `y`.
8. Click the red ball to remove the breakpoint.
9. From the MATLAB Function Block Editor menu, select **Quit Debugging**.
10. Close the editor.
11. Close the figure window.

    Now you are ready for the next task, “Generating C Code” on page 39-189.

Generating C Code

You have proved that your algorithm works in Simulink. Next you generate code for your model.

Note: Before generating code, you must check that your MATLAB code is suitable for code generation. If you call your MATLAB code as an extrinsic function, you must remove extrinsic calls before generating code.

---

1. Rename the `MATLAB Function` block to `Tracking`. To rename the block, double-click the annotation `MATLAB Function` below the `MATLAB Function` block and replace the text with `Tracking`.

   When you generate code for the `MATLAB Function` block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

2. Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

   a. In the Simulink model window, select **Simulation > Model Configuration Parameters**.

      The Configuration Parameters dialog box opens.

   b. In the left pane of the Configuration Parameters dialog box, select **Report** under **Code Generation**.

   c. In the right pane, select **Create code generation report**.

      The **Open report automatically** option is also selected.

   d. Click **Apply** and close the Configuration Parameters dialog box.

   e. Save your model.

3. To generate code for the Tracking block:

   a. In your model, select the Tracking block.

   b. In the Simulink model window, select **Code > C/C++ Code > Build Selected Subsystem**.

4. The Simulink software generates an error informing you that it cannot log variable-size signals as arrays. You need to change the format of data saved to the MATLAB workspace. To change this format:

   - In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.

     The Configuration Parameters dialog box opens.
   - In the left pane of the Configuration Parameters dialog box, select **Data Import/Export** and set the **Format** to `Structure with time`.

     The logged data is now a structure that has two fields: a time field and a signals field, enabling Simulink to log variable-size signals.
   - Click **Apply** and close the Configuration Parameters dialog box.
   - Save your model.

5. Repeat step 3 to generate code for the Tracking block.

   The Simulink Coder software generates C code for the block and launches the code generation report.

   For more information on using the code generation report, see "Reports for Code Generation".

6. In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code. Note that in the code generated for the `MATLAB Function` block, `Tracking`, there is no code for the `ex_kalman03` function because inlining is enabled by default.

7. Modify your filter algorithm to disable inlining:

   a. In `ex_kalman03.m`, after the function declaration, add:

      ```
      coder.inline('never');
      ```

   b. Change the function name to `ex_kalman04` and save the file as `ex_kalman04.m` in the current folder.

   c. In your `ex_kalman33` model, double-click the Tracking block.

      The MATLAB Function Block Editor opens.

   d. Modify the call to the filter algorithm to call `ex_kalman04`.

      ```
      function y = kalman(u)
      ```

```
%#codegen

y = ex_kalman04(u);
```

e Save the model as `ex_kalman44.mdl`.

8 Generate code for the updated model.

a Select the Tracking block.

b In the model window, select **Code** > **C/C++Code** > **Build Selected Subsystem**.

The **Build code for Subsystem** dialog box appears.

c Click the **Build** button.

The Simulink Coder software generates C code for the block and launches the code generation report.

d In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code.

This time the `ex_kalman04` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T
  z_sizes[2], real_T y_data[620], int32_T y_sizes[2]);

/* Function for MATLAB Function Block: '<Root>/Tracking' */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T   48
     z_sizes[2], real_T y_data[620], int32_T y_sizes[2])
```

Best Practices Used in This Tutorial

Best Practice — Saving Incremental Code Updates

Save your code before making modifications. This practice provides a fallback in case of error and a baseline for testing and validation. Use a consistent file naming convention. For example, add a two-digit suffix to the file name for each file in a sequence.

Key Points to Remember

- Back up your MATLAB code before you modify it.

- Decide on a naming convention for your files and save interim versions frequently. For example, this tutorial uses a two-digit suffix to differentiate the various versions of the filter algorithm.
- For simulation purposes, before generating code, call your MATLAB code using `coder.extrinsic` to check that your algorithm is suitable for use in Simulink. This practice provides these benefits:
  - You do not have to make the MATLAB code suitable for code generation.
  - You can debug your MATLAB code in MATLAB while calling it from Simulink.
- Create a Simulink Coder code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

Filter Audio Signal Using MATLAB Code

In this section...
"Learning Objectives" on page 39-193
"Tutorial Prerequisites" on page 39-193
"Example: The LMS Filter" on page 39-194
"Files for the Tutorial" on page 39-196
"Tutorial Steps" on page 39-198

Learning Objectives

In this tutorial, you will learn how to:

- Use the `MATLAB Function` block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

  This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.
- Use `coder.extrinsic` to call MATLAB code from a `MATLAB Function` block.

  This capability allows you to call existing MATLAB code from Simulink without first having to make this code suitable for code generation, allowing for rapid prototyping.
- Check that existing MATLAB code is suitable for code generation.
- Convert a MATLAB algorithm from batch processing to streaming.
- Use persistent variables in code that is suitable for code generation.

  You need to make the filter weights persistent so that the filter algorithm does not reset their values each time it runs.

Tutorial Prerequisites

- "What You Need to Know" on page 39-194
- "Required Products" on page 39-194

What You Need to Know

To work through this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create a basic Simulink model and how to simulate that model. For more information, see "Create Simple Model".

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- DSP System Toolbox
- C compiler

  For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

For instructions on installing MathWorks products, refer to the installation documentation. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window. For instructions on installing and setting up a C compiler, see "Setting Up the C or C++ Compiler".

Example: The LMS Filter

- "Description" on page 39-194
- "Algorithm" on page 39-195
- "Filtering Process" on page 39-196
- "Reference" on page 39-196

Description

A least mean squares (LMS) filter is an adaptive filter that adjusts its transfer function according to an optimizing algorithm. You provide the filter with an example of the desired signal together with the input signal. The filter then calculates the filter weights, or coefficients, that produce the least mean squares of the error between the output signal and the desired signal.

This example uses an LMS filter to remove the noise in a music recording. There are two inputs. The first input is the distorted signal: the music recording plus the filtered noise. The second input is the desired signal: the unfiltered noise. The filter works to eliminate the difference between the output signal and the desired signal and outputs the difference, which, in this case, is the clean music recording. When you start the simulation, you hear both the noise and the music. Over time, the adaptive filter removes the noise so you hear only the music.

Algorithm

This example uses the least mean squares (LMS) algorithm to remove noise from an input signal. The LMS algorithm computes the filtered output, filter error, and filter weights given the distorted and desired signals.

At the start of the tutorial, the LMS algorithm uses a batch process to filter the audio input. This algorithm is suitable for MATLAB, where you are likely to load in the entire signal and process it all at once. However, a batch process is not suitable for processing a signal in real time. As you work through the tutorial, you refine the design of the filter to convert the algorithm from batch-based to stream-based processing.

The baseline function signature for the algorithm is:

```
function [ signal_out, err, weights ] = ...
    lms_01(signal_in, desired)
```

The filtering is performed in the following loop:

```
for n = 1:SignalLength
  % Compute the output sample using convolution:
  signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
  % Update the filter coefficients:
  err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
  weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
end
```

where `SignalLength` is the length of the input signal, `FilterLength` is the filter length, and `mu` is the adaptation step size.

What Is the Adaptation Step Size?

LMS algorithms have a step size that determines the amount of correction to apply as the filter adapts from one iteration to the next. Choosing the appropriate step size requires experience in adaptive filter design. A step size that is too small increases the time for the filter to converge. Filter convergence is the process where the error

signal (the difference between the output signal and the desired signal) approaches an equilibrium state over time. A step size that is too large might cause the adapting filter to overshoot the equilibrium and become unstable. Generally, smaller step sizes improve the stability of the filter at the expense of the time it takes to adapt.

Filtering Process

The filtering process has three phases:

- Convolution

  The convolution for the filter is performed in:

  ```
  signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
  ```

  #### What Is Convolution?

  Convolution is the mathematical foundation of filtering. In signal processing, convolving two vectors or matrices is equivalent to filtering one of the inputs by the other. In this implementation of the LMS filter, the convolution operation is the vector dot product between the filter weights and a subset of the distorted input signal.

- Calculation of error

  The error is the difference between the desired signal and the output signal:

  ```
  err(n,ch) = desired(n,ch) - signal_out(n,ch);
  ```

- Adaptation

  The new value of the filter weights is the old value of the filter weights plus a correction factor that is based on the error signal, the distorted signal, and the adaptation step size:

  ```
  weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
  ```

Files for the Tutorial

- “About the Tutorial Files” on page 39-197

- "Location of Files" on page 39-197
- "Names and Descriptions of Files" on page 39-197

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- MATLAB code files for each step of the example.

  Throughout this tutorial, you work with Simulink models that call MATLAB files that contain a simple least mean squares (LMS) filter algorithm.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\lms`. To run the tutorial, you must copy these files to a local folder. For instructions, see "Copying Files Locally" on page 39-198.

Names and Descriptions of Files

Type	Name	Description
MATLAB files	`lms_01`	Baseline MATLAB implementation of batch filter. Not suitable for code generation.
	`lms_02`	Filter modified from batch to streaming.
	`lms_03`	Frame-based streaming filter with Reset and Adapt controls.
	`lms_04`	Frame-based streaming filter with Reset and Adapt controls. Suitable for code generation.
	`lms_05`	Disabled inlining for code generation.
	`lms_06`	Demonstrates use of `coder.nullcopy`.
Simulink model files	`acoustic_environment`	Simulink model that provides an overview of the acoustic environment.
	`noise_cancel_00`	Simulink model without a `MATLAB Function` block.
	`noise_cancel_01`	Complete `noise_cancel_00` model including a `MATLAB Function` block.

Type	Name	Description
	noise_cancel_02	Simulink model for use with lms_02.m.
	noise_cancel_03	Simulink model for use with lms_03.m.
	noise_cancel_04	Simulink model for use with lms_04.m.
	noise_cancel_05	Simulink model for use with lms_05.m.
	noise_cancel_06	Simulink model for use with lms_06.m.
	design_templates	Simulink model containing Adapt and Reset controls.

Tutorial Steps

- "Copying Files Locally" on page 39-198
- "Setting Up Your C Compiler" on page 39-199
- "Running the acoustic_environment Model" on page 39-199
- "Adding a MATLAB Function Block to Your Model" on page 39-200
- "Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping" on page 39-201
- "Simulating the noise_cancel_01 Model" on page 39-203
- "Modifying the Filter to Use Streaming" on page 39-205
- "Adding Adapt and Reset Controls" on page 39-210
- "Generating Code" on page 39-214
- "Optimizing the LMS Filter Algorithm" on page 39-218

Copying Files Locally

Copy the tutorial files to a local folder:

1. Create a local *solutions* folder, for example, `c:\test\lms\solutions`.
2. Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

   ```
   cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
   ```
3. Copy the contents of the `lms` subfolder to your *solutions* folder, specifying the full path name of the *solutions* folder:

   ```
   copyfile('lms', 'solutions')
   ```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task, you can view the supplied solution to see how the code should look.

4 Create a local *work* folder, for example, `c:\test\lms\work`.

5 Copy the following files from your *solutions* folder to your *work* folder.

- `lms_01`
- `lms_02`
- `noise_cancel_00`
- `acoustic_environment`
- `design_templates`

Your *work* folder now contains all the files that you need to get started.

You are now ready to set up your C compiler.

Setting Up Your C Compiler

Building your `MATLAB Function` block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” and the list of .

Running the acoustic_environment Model

Run the `acoustic_environment` model supplied with the tutorial to understand the problem that you are trying to solve using the LMS filter. This model adds band-limited white noise to an audio signal and outputs the resulting signal to a speaker.

To simulate the model:

1 Open the `acoustic_environment` model in Simulink:

a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files. See “Find Files and Folders” for more information.

b At the MATLAB command line, enter:

```
acoustic_environment
```

2 Ensure that your speakers are on.

3 To simulate the model, from the Simulink model window, select **Simulation** > **Run**.

As Simulink runs the model, you hear the audio signal distorted by noise.

4 While the simulation is running, double-click the `Manual Switch` to select the audio source.

Now you hear the desired audio input without any noise.

The goal of this tutorial is to use a MATLAB LMS filter algorithm to remove the noise from the noisy audio signal. You do this by adding a `MATLAB Function` block to the model and calling the MATLAB code from this block.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_01` in your *`solutions`* subfolder to see the modified model.

For the purposes of this tutorial, you add the `MATLAB Function` block to the `noise_cancel_00` model supplied with the tutorial. In practice, you would have to develop your own test bench starting with an empty Simulink model.

To add a `MATLAB Function` block to the `noise_cancel_00` model:

1 Open `noise_cancel_00` in Simulink.

```
noise_cancel_00
```

2 Add a `MATLAB Function` block to the model:

a At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.

b From the list of Simulink libraries, select the `User-Defined Functions` library.

c Click the `MATLAB Function` block and drag it into the `noise_cancel_00` model. Place the block just above the red text annotation `Place MATLAB Function Block here`.

d Delete the red text annotations from the model.

e Save the model in the current folder as `noise_cancel_01`.

Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping

In this part of the tutorial, you use the `coder.extrinsic` function to call your MATLAB code from the `MATLAB Function` block for rapid prototyping.

Why Call MATLAB Code As an Extrinsic Function?

Calling MATLAB code as an extrinsic function provides these benefits:

- For rapid prototyping, you do not have to make the MATLAB code suitable for code generation.
- Using `coder.extrinsic` enables you to debug your MATLAB code in MATLAB. You can add one or more breakpoints in the `lms_01.m` file, and then start the simulation in Simulink. When the MATLAB execution engine encounters a breakpoint, it temporarily halts execution so that you can inspect the MATLAB workspace and view the current values of all variables in memory. For more information about debugging MATLAB code, see "Debug a MATLAB Program".

How to Call MATLAB Code As an Extrinsic Function

To call your MATLAB code from the `MATLAB Function` block:

1. Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.
2. Delete the default code displayed in the MATLAB Function Block Editor.
3. Copy the following code to the `MATLAB Function` block.

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In) %#codegen
    % Extrinsic:
    coder.extrinsic('lms_01');

    % Compute LMS:
    [ ~, Signal_Out, Weights ] = lms_01(Noise_In, Signal_In);
end
```

Why Use the Tilde (~) Operator?

Because the `LMS` function does not use the first output from `lms_01`, replace this output with the MATLAB ~ operator. MATLAB ignores inputs and outputs specified by ~. This syntax helps avoid confusion in your program code and unnecessary

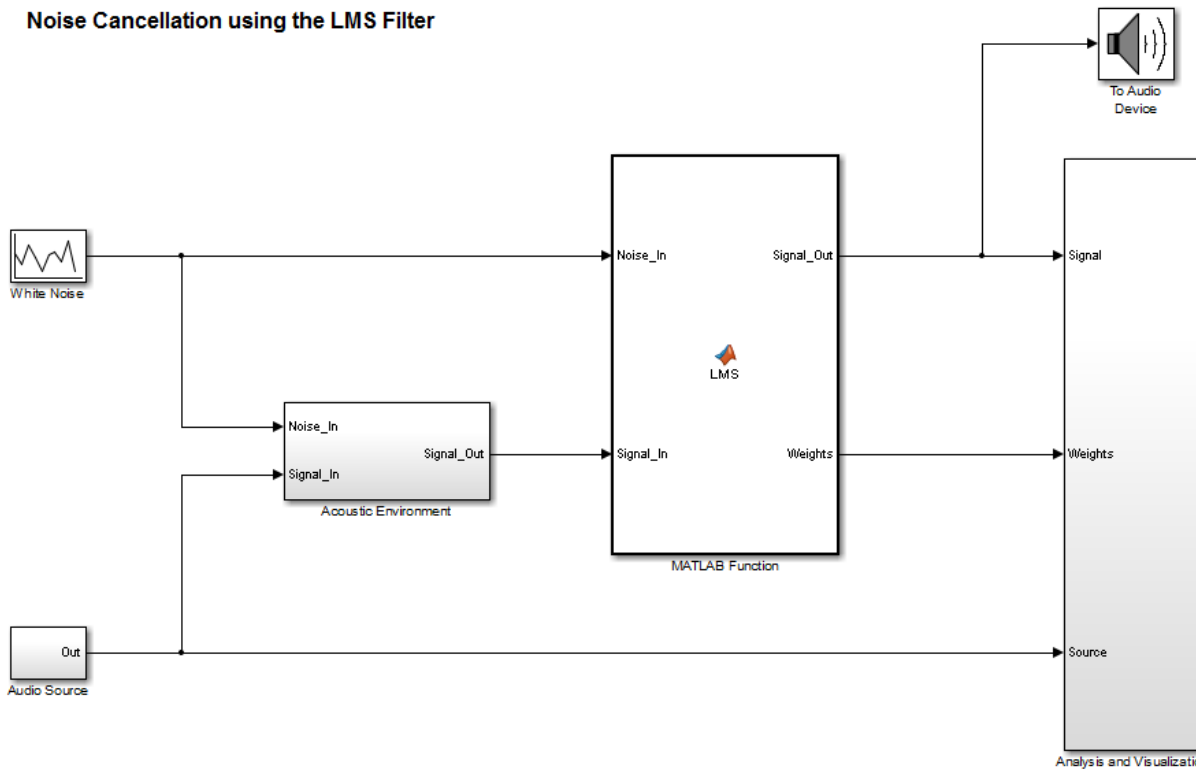
clutter in your workspace, and allows you to reuse existing algorithms without modification.

4 Save the model.

The `lms_01` function inputs `Noise_In` and `Signal_In` now appear as input ports to the block and the function outputs `Signal_Out` and `Weights` appear as output ports.

Connecting the MATLAB Function Block Inputs and Outputs

1 Connect the `MATLAB Function` block inputs and outputs so that your model looks like this.



See "Block and Signal Line Shortcuts and Actions" on page 1-86 for more information.

2 In the `MATLAB Function` block code, preallocate the outputs by adding the following code after the extrinsic call:

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

The size of `Weights` is set to match the Numerator coefficients of the Digital Filter in the Acoustic Environment subsystem.

Why Preallocate the Outputs?

For code generation, you must assign variables explicitly to have a specific class, size, and complexity before using them in operations or returning them as outputs in MATLAB functions. For more information, see "Differences in Behavior After Compiling MATLAB Code" on page 43-8.

3 Save the model.

You are now ready to check your model for errors.

Simulating the noise_cancel_01 Model

To simulate the model:

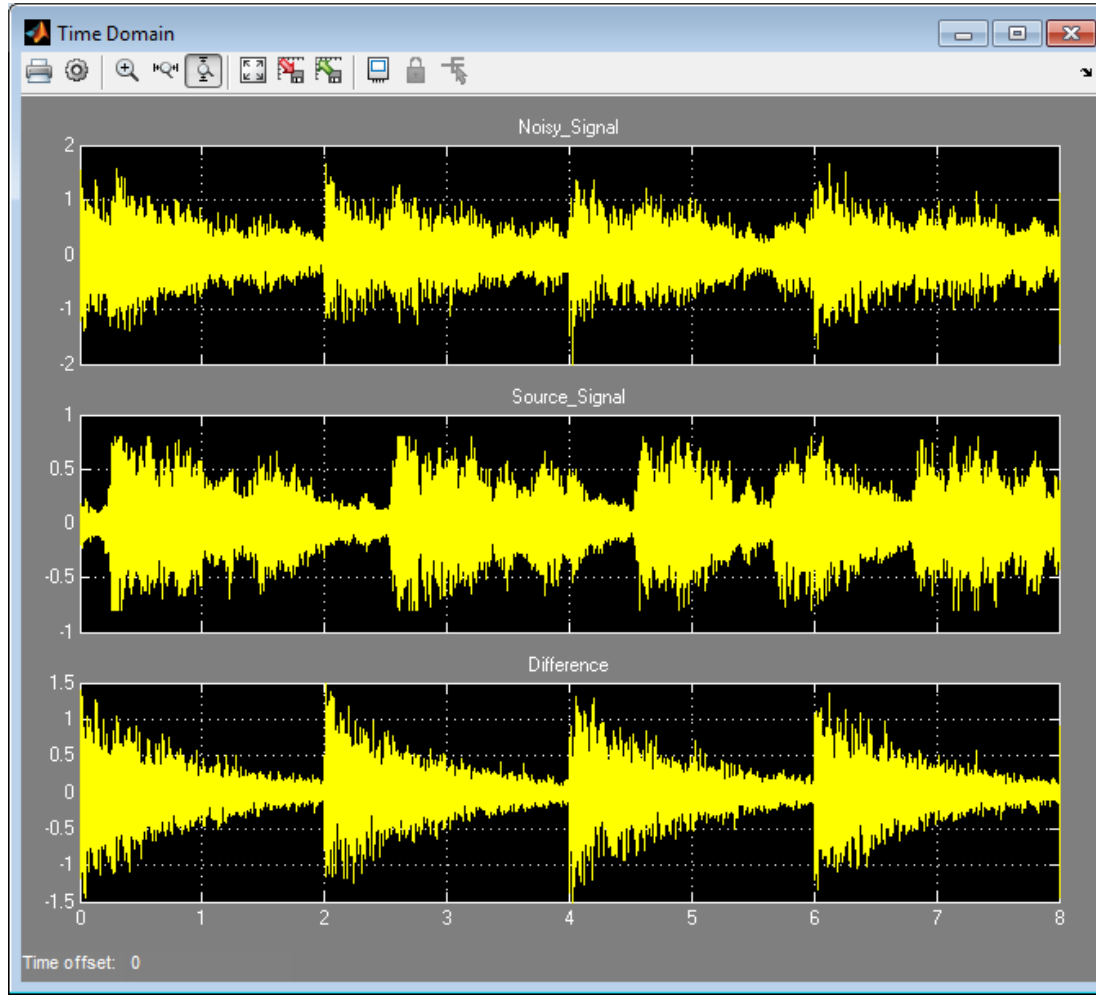
1 Ensure that you can see the **Time Domain** plots.

To view the plots, in the `noise_cancel_01` model, open the `Analysis and Visualization` block and then open the `Time Domain` block.

2 In the Simulink model window, select **Simulation** > **Run** .

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. After two seconds, you hear the distorted noisy signal again and the filter attenuates the noise again. This cycle repeats continuously.

MATLAB displays the following plot showing this cycle.



3 Stop the simulation.

Why Does the Filter Reset Every 2 Seconds?

The filter resets every 2 seconds because the model uses 16384 samples per frame and a sampling rate of 8192, so the 16384 samples represent 2 seconds of audio.

To see the model configuration:

1. Double-click the White Noise subsystem and note that it uses a **Sample time** of `1/Fs` and **Samples per frame** of `FrameSize`. The `music` in the Audio Source subsystem also uses these values.
2. `FrameSize` is set in the model `InitFcn` callback. To view this callback:
   a. Right-click inside the model window and select **Model Properties** from the context menu.
   b. Select the **Callbacks** tab.
   c. Select `InitFcn` in the **Model callbacks** pane.

   Note that `FrameSize = 16*1024`, which is `16384`.
3. `Fs` is set in the model `PostLoadFcn` callback. To view this callback, select `PostLoadFcn` in the **Model callbacks** pane:

   The following MATLAB commands set up `Fs`:

```
data = load('handel.mat');
music = data.y;
Fs = data.Fs;
```

Modifying the Filter to Use Streaming

- "What Is Streaming?" on page 39-205
- "Why Use Streaming?" on page 39-205
- "Viewing the Modified MATLAB Code" on page 39-206
- "Summary of Changes to the Filter Algorithm" on page 39-206
- "Modifying Your Model to Call the Updated Algorithm" on page 39-207
- "Simulating the Streaming Algorithm" on page 39-208

What Is Streaming?

A streaming filter is called repeatedly to process fixed-size chunks of input data, or *frames*, until it has processed the entire input signal. The frame size can be as small as a single sample, in which case the filter would be operating in a sample-based mode, or up to a few thousand samples, for frame-based processing.

Why Use Streaming?

The design of the filter algorithm in `lms_01` has the following disadvantages:

- The algorithm does not use memory efficiently.

Preallocating a fixed amount of memory for each input signal for the lifetime of the program means more memory is allocated than is in use.

- You must know the size of the input signal at the time you call the function.

  If the input signal is arriving in real time or as a stream of samples, you would have to wait to accumulate the entire signal before you could pass it, as a batch, to the filter.
- The signal size is limited to a maximum size.

In an embedded application, the filter is likely to be processing a continuous input stream. As a result, the input signal can be substantially longer than the maximum length that a filter working in batch mode could possibly handle. To make the filter work for any signal length, it must run in real time. One solution is to convert the filter from batch-based processing to stream-based processing.

Viewing the Modified MATLAB Code

The conversion to streaming involves:

- Introducing a first-in, first-out (FIFO) queue

  The FIFO queue acts as a temporary storage buffer, which holds a small number of samples from the input data stream. The number of samples held by the FIFO queue must be exactly the same as the number of samples in the filter's impulse response, so that the function can perform the convolution operation between the filter coefficients and the input signal.
- Making the FIFO queue and the filter weights persistent

  The filter is called repeatedly until it has processed the entire input signal. Therefore, the FIFO queue and filter weights need to persist so that the adaptation process does not have to start over again after each subsequent call to the function.

Open the supplied file `lms_02.m` in your *`work`* subfolder to see the modified algorithm.

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The filter weights and the FIFO queue are declared as persistent:

```
persistent weights;
persistent fifo;
```

- The FIFO queue is initialized:

```
fifo = zeros(FilterLength,ChannelCount);
```

- The FIFO queue is used in the filter update loop:

```
% For each channel:
for ch = 1:ChannelCount

   % For each sample time:
   for n = 1:FrameSize

     % Update the FIFO shift register:
     fifo(1:FilterLength-1,ch) = fifo(2:FilterLength,ch);
     fifo(FilterLength,ch) = signal_in(n,ch);

     % Compute the output sample using convolution:
     signal_out(n,ch) = weights' * fifo(:,ch);

     % Update the filter coefficients:
     err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
     weights = weights + mu*err(n,ch)*fifo(:,ch);

   end
end
```

- You cannot output a persistent variable. Therefore, a new variable, `weights_out`, is used to output the filter weights:

```
function [ signal_out, err, weights_out ] = ...
  lms_02(distorted, desired)

weights_out = weights;
```

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_02` in your *`solutions`* subfolder to see the modified model.

1. In the `noise_cancel_01` model, double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.
2. Modify the `MATLAB Function` block code to call `lms_02`.
   a. Modify the extrinsic call.

```
% Extrinsic:
coder.extrinsic('lms_02');
```

b Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
```

Modified MATLAB Function Block Code

Your `MATLAB Function` block code should now look like this:

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In)
  % Extrinsic:
  coder.extrinsic('lms_02');
  % Outputs:
  Signal_Out = zeros(size(Signal_In));
  Weights = zeros(32,1);
  % Compute LMS:
  [ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
end
```

3 Change the frame size from `16384` to `64`, which represents a more realistic value.

a Right-click inside the model window and select **Model Properties** from the context menu.

b Select the **Callbacks** tab.

c In the **Model callbacks** list, select `InitFcn`.

d Change the value of `FrameSize` to `64`.

e Click **Apply** and close the dialog box.

4 Save your model as `noise_cancel_02`.

Simulating the Streaming Algorithm

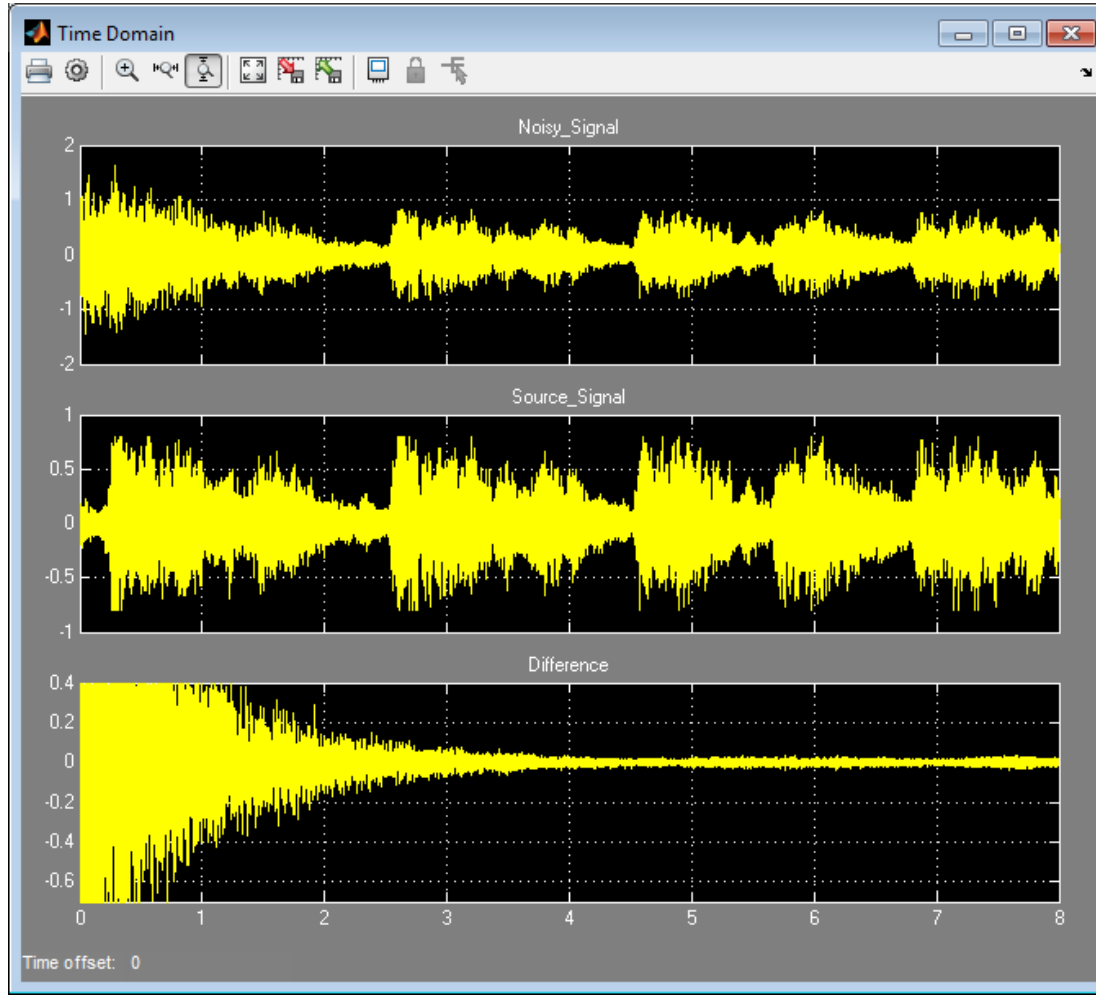
To simulate the model:

1 Ensure that you can see the **Time Domain** plots.

2 Start the simulation.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then, during the first few seconds, the filter attenuates the noise gradually, until you hear only the music playing with very little noise

remaining. MATLAB displays the following plot showing filter convergence after only a few seconds.



3 Stop the simulation.

The filter algorithm is now suitable for Simulink. You are ready to elaborate your model to use `Adapt` and `Reset` controls.

Adding Adapt and Reset Controls

- "Why Add Adapt and Reset Controls?" on page 39-210
- "Modifying Your MATLAB Code" on page 39-210
- "Modifying Your Model to Use Reset and Adapt Controls" on page 39-211
- "Simulating the Model with Adapt and Reset Controls" on page 39-213

Why Add Adapt and Reset Controls?

In this part of the tutorial, you add Adapt and Reset controls to your filter. Using these controls, you can turn the filtering on and off. When `Adapt` is enabled, the filter continuously updates the filter weights. When `Adapt` is disabled, the filter weights remain at their current values. If `Reset` is set, the filter resets the filter weights.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `lms_03.m` in your *`solutions`* subfolder to see the modified algorithm.

To modify your filter code:

1. Open `lms_02.m`.
2. In the `Set up` section, replace

   ```
   if ( isempty(weights) )
   ```

   with

   ```
   if ( reset || isempty(weights) )
   ```
3. In the filter loop, update the filter coefficients only if `Adapt` is `ON`.

   ```
   if adapt
     weights = weights + mu*err(n,ch)*fifo(:,ch);
   end
   ```
4. Change the function signature to use the `Adapt` and `Reset` inputs and change the function name to `lms_03`.

   ```
   function [ signal_out, err, weights_out ] = ...
     lms_03(signal_in, desired, reset, adapt)
   ```
5. Save the file in the current folder as `lms_03.m`:

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The new input parameter `reset` is used to determine if it is necessary to reset the filter coefficients:

```
if ( reset || isempty(weights) )
  % Filter coefficients:
  weights = zeros(L,1);
  % FIFO Shift Register:
  fifo = zeros(L,1);
end
```

- The new parameter `adapt` is used to control whether the filter coefficients are updated or not.

```
if adapt
  weights = weights + mu*err(n)*fifo;
end
```

Modifying Your Model to Use Reset and Adapt Controls

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_03` in your *`solutions`* subfolder to see the modified model.

1. Open the `noise_cancel_02` model.
2. Double-click the `MATLAB Function` block to open the MATLAB Function Block Editor.
3. Modify the `MATLAB Function` block code:
   a. Update the function declaration.

```
function [ Signal_Out, Weights ] = ...
   LMS(Adapt, Reset, Noise_In, Signal_In )
```

   b. Update the extrinsic call.

```
coder.extrinsic('lms_03');
```

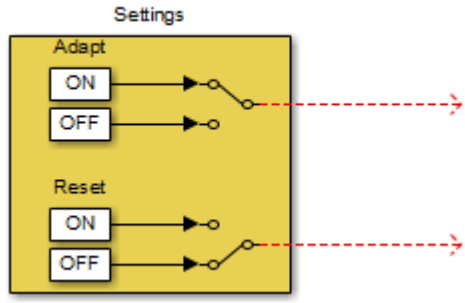
   c. Update the call to the LMS algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
   lms_03(Noise_In, Signal_In, Reset, Adapt);
```

   d. Close the MATLAB Function Block Editor.

The `lms_03` function inputs `Reset` and `Adapt` now appear as input ports to the `MATLAB Function` block.

4 Open the `design_templates` model.



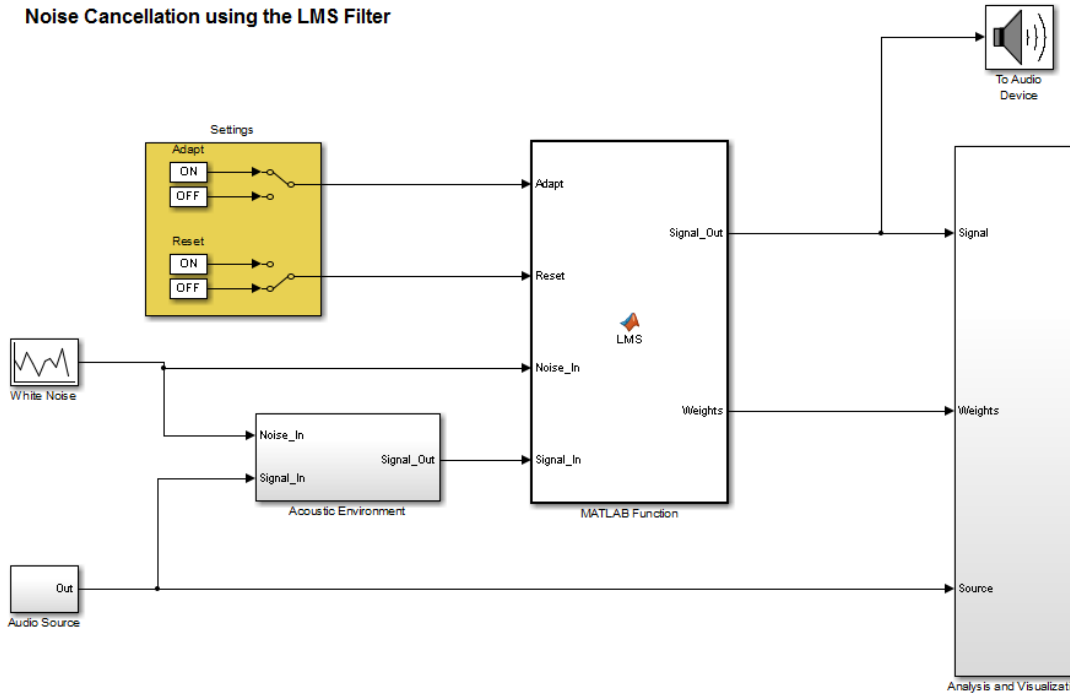
5 Copy the Settings block from this model to your `noise_cancel_02` model:

   a From the `design_templates` model menu, select **Edit** > **Select All**.

   b Select **Edit** > **Copy**.

   c From the `noise_cancel_02` model menu, select **Edit** > **Paste**.

6 Connect the Adapt and Reset outputs of the Settings subsystem to the corresponding inputs on the `MATLAB Function` block. Your model should now appear as follows.



7 Save the model as `noise_cancel_03`.

Simulating the Model with Adapt and Reset Controls

To simulate the model and see the effect of the Adapt and Reset controls:

1 In the `noise_cancel_03` model, view the Convergence scope:

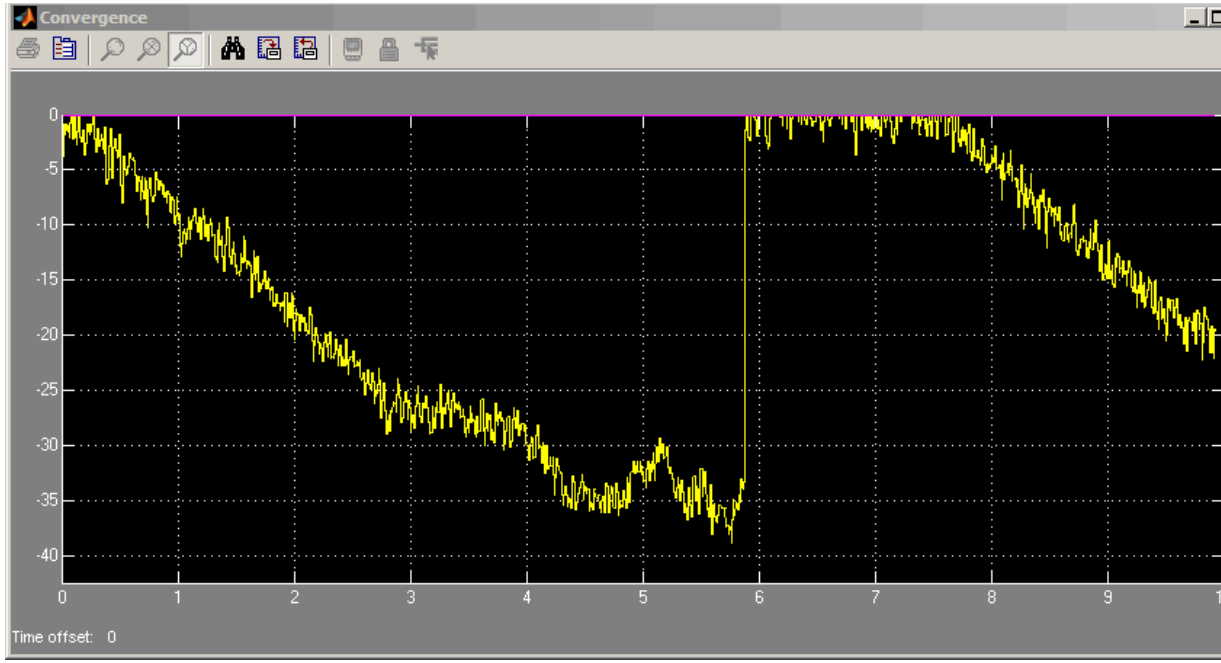
   a Double-click the Analysis and Visualization subsystem.

   b Double-click the Convergence scope.

2 In the Simulink model window, select **Simulation > Run**.

   Simulink runs the model as before. While the model is running, toggle the Adapt and Reset controls and view the Convergence scope to see their effect on the filter.

   The filter converges when `Adapt` is `ON` and `Reset` is `OFF`, then resets when you toggle`Reset`. The results might look something like this:



3 Stop the simulation.

Generating Code

You have proved that your algorithm works in Simulink. Next you generate code for your model. Before generating code, you must ensure that your MATLAB code is suitable for code generation. For code generation, you must remove the extrinsic call to your code.

Making Your Code Suitable for Code Generation

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_04` and file `lms_04.m` in your *`solutions`* subfolder to see the modifications.

1 Rename the `MATLAB Function` block to `LMS_Filter`. Select the annotation `MATLAB Function` below the `MATLAB Function` block and replace the text with `LMS_Filter`.

When you generate code for the `MATLAB Function` block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

2. In your `noise_cancel_03` model, double-click the `MATLAB Function` block.

   The MATLAB Function Block Editor opens.

3. Delete the extrinsic declaration.

   ```
   % Extrinsic:
   coder.extrinsic('lms_03');
   ```

4. Delete the preallocation of outputs.

   ```
   % Outputs:
   Signal_Out = zeros(size(Signal_In));
   Weights = zeros(32,1);
   ```

5. Modify the call to the filter algorithm.

   ```
   % Compute LMS:
   [ ~, Signal_Out, Weights ] = ...
      lms_04(Noise_In, Signal_In, Reset, Adapt);
   ```

6. Save the model as `noise_cancel_04`.

7. Open `lms_03.m`

   a. Modify the function name to `lms_04`.

   b. Turn on error checking specific to code generation by adding the `%#codegen` compilation directive after the function declaration.

      ```
      function [ signal_out, err, weights_out ] = ...
          lms_04(signal_in, desired, reset, adapt) %#codegen
      ```

      The code analyzer message indicator in the top right turns red to indicate that the code analyzer has detected code generation issues. The code analyzer underlines the offending code in red and places a red marker to the right of it.

8. Move your pointer over the first red marker to view the error information.

   The code analyzer detects that code generation requires `signal_out` to be fully defined before subscripting it and does not support growth of variable size data through indexing.

9 Move your pointer over the second red marker and note that the code analyzer detects the same errors for `err`.

10 To address these errors, preallocate the outputs `signal_out` and `err`. Add this code after the filter setup.

```
% Output Arguments:

% Pre-allocate output and error signals:
signal_out = zeros(FrameSize,ChannelCount);
err = zeros(FrameSize,ChannelCount);
```

Why Preallocate the Outputs?

You must preallocate outputs here because code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See "Preallocating Memory".

The red error markers for the two lines of code disappear. The code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

11 Save the file as `lms_04.m`.

Generating Code for noise_cancel_04

1 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

   a In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.

   b In the left pane of the Configuration Parameters dialog box, select **Code Generation** > **Report**.

   c In the right pane, select **Create code generation report**.

   The **Launch report automatically** option is also selected.

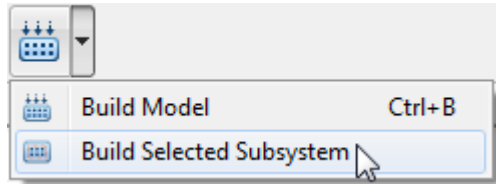
   d Click **Apply** and close the Configuration Parameters dialog box.

   e Save your model.

2 To generate code for the LMS Filter subsystem:

a In your model, select the LMS Filter subsystem.

b From the Build Model tool menu, select **Build Selected Subsystem**.



The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

For more information on using the code generation report, see "Generate a Code Generation Report" in the Simulink Coder documentation.

c In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code. Note that the `lms_04` function has no code because inlining is enabled by default.

3 Modify your filter algorithm to disable inlining:

a In `lms_04.m`, after the function declaration, add:

```
coder.inline('never')
```

b Change the function name to `lms_05` and save the file as `lms_05.m` in the current folder.

c In your `noise_cancel_04` model, double-click the `MATLAB Function` block.

The MATLAB Function Block Editor opens.

d Modify the call to the filter algorithm to call `lms_05`.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
   lms_05(Noise_In, Signal_In, Reset, Adapt);
```

e Save the model as `noise_cancel_05`.

4 Generate code for the updated model.

a In the model, select the LMS Filter subsystem.

b From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears.

c Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

d In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

This time the `lms_05` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
   static void LMS_Filter_lms_05 ...
       (const real_T signal_in[64],const real_T ...
       desired[64], real_T reset, real_T adapt, ...
             real_T signal_out[64], ...
      real_T err[64], real_T weights_out[32]);

/* Function for MATLAB Function Block: 'root/LMS_Filter' */
   static void LMS_Filter_lms_05 ...
      (const real_T signal_in[64], const real_T ...
         desired[64], real_T reset, real_T adapt, ...
             real_T signal_out[64], ...
     real_T err[64], real_T weights_out[32])
```

Optimizing the LMS Filter Algorithm

This part of the tutorial demonstrates when and how to preallocate memory for a variable without incurring the overhead of initializing memory in the generated code.

In `lms_05.m`, the MATLAB code not only declares `signal_out` and `err` to be a `FrameSize`-by-`ChannelCount` vector of real doubles, but also initializes each element of `signal_out` and `err` to zero. These signals are initialized to zero in the generated C code.

MATLAB Code	Generated C Code

`% Pre-allocate output and error signals:`
`signal_out =`
`zeros(FrameSize,ChannelCount);`
`err = zeros(FrameSize,ChannelCount);`
	`/* Pre-allocate output and error signals: */`
	`79 for (i = 0; i < 64; i++) {`
	`80 signal_out[i] = 0.0;`

MATLAB Code	Generated C Code
	81 err[i] = 0.0; 82 }

This forced initialization is unnecessary because both `signal_out` and `err` are explicitly initialized in the MATLAB code before they are read.

Note: You should not use `coder.nullcopy` when declaring the variables `weights` and `fifo` because these variables need to be initialized in the generated code. Neither variable is explicitly initialized in the MATLAB code before they are read.

Use `coder.nullcopy` in the declaration of `signal_out` and `err` to eliminate the unnecessary initialization of memory in the generated code:

1. In `lms_05.m`, preallocate `signal_out` and `err` using `coder.nullcopy`:

   ```
   % Pre-allocate output and error signals:
   signal_out = coder.nullcopy(zeros(FrameSize, ChannelCount));
   err = coder.nullcopy(zeros(FrameSize, ChannelCount));
   ```

   Caution After declaring a variable with `coder.nullcopy`, you must explicitly initialize the variable in your MATLAB code before reading it. Otherwise, you might get unpredictable results.

   ---

2. Change the function name to `lms_06` and save the file as `lms_06.m` in the current folder.
3. In your `noise_cancel_05` model, double-click the `MATLAB Function` block.

   The `MATLAB Function Block` Editor opens.
4. Modify the call to the filter algorithm.

   ```
   % Compute LMS:
   [ ~, Signal_Out, Weights ] = ...
      lms_06(Noise_In, Signal_In, Reset, Adapt);
   ```
5. Save the model as `noise_cancel_06`.

Generate code for the updated model.

1. Select the LMS Filter subsystem.

2 From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software and generates C code for the subsystem and launches the code generation report.

3 In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

In the generated C code, this time there is no initialization to zero of `signal_out` and `err`.

Encapsulating the Interface to External Code

Use the `coder.ExternalDependency` class to encapsulate the interface between external code and MATLAB code intended for code generation. With the encapsulation, you can separate the details of the interface from your MATLAB code. The methods of `coder.ExternalDependency`:

- specify the location of external files
- update build information
- define the programming interface for external functions

In your MATLAB code, you can call the external code without providing build information.

The workflow is:

1. Write a class definition file for a class that derives from `coder.ExternalDependency`.
2. Store the class definition file in a folder on the MATLAB path.
3. In your MATLAB code, use a method of the class to call an external function.
4. Generate code from your MATLAB code.

More About

- “Best Practices for Using coder.ExternalDependency” on page 39-225

Encapsulate Interface to an External C Library

This example shows how to encapsulate the interface to an external C dynamic linked library using `coder.ExternalDependency`.

Write a function `adder` that returns the sum of its inputs.

```
function c = adder(a,b)
    %#codegen
    c = a + b;
end
```

Generate a library that contains `adder`.

```
codegen('adder','-args', {-2,5}, '-config:dll', '-report');
```

Write the class definition file `AdderAPI.m` to encapsulate the library interface.

```
%=============================================================
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
%=============================================================

classdef AdderAPI < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(~)
            bName = 'AdderAPI';
        end

        function tf = isSupportedContext(ctx)
            if  ctx.isMatlabHostTarget()
                tf = true;
            else
                error('adder library not available for this target');
            end
        end

        function updateBuildInfo(buildInfo, ctx)
            [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo();

            % Header files
```

```
    hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
    buildInfo.addIncludePaths(hdrFilePath);

    % Link files
    linkFiles = strcat('adder', linkLibExt);
    linkPath = hdrFilePath;
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    % Non-build files
    nbFiles = 'adder';
    nbFiles = strcat(nbFiles, execLibExt);
    buildInfo.addNonBuildFiles(nbFiles,'','');
end

%API for library function 'adder'
function c = adder(a, b)
    if coder.target('MATLAB')
        % running in MATLAB, use built-in addition
        c = a + b;
    else
        % running in generated code, call library function
        coder.cinclude('adder.h');

        % Because MATLAB Coder generated adder, use the
        % housekeeping functions before and after calling
        % adder with coder.ceval.
        % Call initialize function before calling adder for the
        % first time.

        coder.ceval('adder_initialize');
        c = 0;
        c = coder.ceval('adder', a, b);

        % Call the terminate function after
        % calling adder for the last time.

        coder.ceval('adder_terminate');
    end
```

```
        end
    end
end
```

Write a function `adder_main` that calls the external library function `adder`.

```
function y = adder_main(x1, x2)
%#codegen
    y = AdderAPI.adder(x1, x2);
end
```

Generate a MEX function for `adder_main`. The MEX Function exercises the `coder.ExternalDependency` methods.

```
codegen('adder_main', '-args', {7,9}, '-report')
```

Copy the library to the current folder using the file extension for your platform.

For Windows, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dll'));
```

For Linux, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.so'));
```

Run the MEX function and verify the result.

```
adder_main_mex(2,3)
```

More About

- “Encapsulating the Interface to External Code” on page 39-221

Best Practices for Using coder.ExternalDependency

In this section...
“Terminate Code Generation for Unsupported External Dependency” on page 39-225
“Parameterize Methods for MATLAB and Generated Code” on page 39-225
“Parameterize updateBuildInfo for Multiple Platforms” on page 39-226

Terminate Code Generation for Unsupported External Dependency

The `isSupportedContext` method returns true if the external code interface is supported in the build context. If the external code interface is not supported, do not return false. Instead, use `error` to terminate code generation with an error message. For example:

```
function tf = isSupportedContext(ctx)
    if  ctx.isMatlabHostTarget()
        tf = true;
    else
        error('MyLibrary is not available for this target');
    end
end
```

Parameterize Methods for MATLAB and Generated Code

Parameterize methods that call external functions so that the methods run in MATLAB. For example:

```
...
if coder.target('MATLAB')
    % running in MATLAB, use built-in addition
    c = a + b;
else
    % running in generated code, call library function
    coder.ceval('adder_initialize');
end
...
```

Parameterize updateBuildInfo for Multiple Platforms

Parameterize the `updateBuildInfo` method to support multiple platforms. For example, use `coder.BuildConfig.getStdLibInfo` to get the platform-specific library file extensions.

```
...
    [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo()
% Link files
linkFiles =  strcat('adder', linkLibExt);
buildInfo.addLinkObjects(linkFiles, linkPath, linkPriority, ...
    linkPrecompiled, linkLinkOnly, group);
...
```

Update Build Information from MATLAB code

You can choose to control aspects of the build process that occur after code generation but before compilation. For example, you can specify compiler or linker options.

To customize the build from your MATLAB code:

1. In your MATLAB code, call `coder.updateBuildInfo` to update the build information object. You specify a build information object method and the input arguments for the method.
2. Generate code from your MATLAB code.

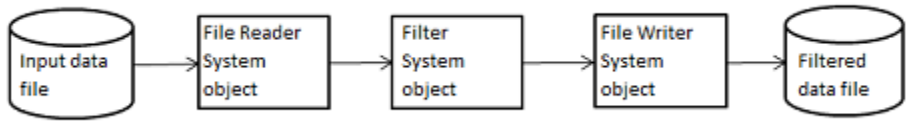
- "System Object Methods" on page 40-14
- "System Design in Simulink Using System Objects" on page 40-17

What Are System Objects?

A System object is a specialized kind of MATLAB object. System Toolboxes include System objects and most System Toolboxes also have MATLAB functions and Simulink blocks. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time. Many signal processing, communications, and controls systems are dynamic. In a dynamic system, the values of the output signals depend on both the instantaneous values of the input signals and on the past behavior of the system. System objects use internal states to store that past behavior, which is used in the next computational step. As a result, System objects are optimized for iterative computations that process large streams of data, such as video and audio processing systems.

For example, you could use System objects in a system that reads data from a file, filters that data and then writes the filtered output to another file. Typically, a specified amount of data is passed to the filter in each loop iteration. The file reader object uses a state to keep track of where in the file to begin the next data read. Likewise, the file writer object keeps tracks of where it last wrote data to the output file so that data is not overwritten. The filter object maintains its own internal states to assure that the filtering is performed correctly. This diagram represents a single loop of the system.



Many System objects support:

- Fixed-point arithmetic (requires a Fixed-Point Designer license)
- C code generation (requires a MATLAB Coder or Simulink Coder license)
- HDL code generation (requires an HDL Coder license)
- Executable files or shared libraries generation (requires a MATLAB Compiler™ license)

Note: Check your product documentation to confirm fixed-point, code generation, and MATLAB Compiler support for the specific System objects you want to use.

In addition to the System objects provided with System Toolboxes, you can also create your own System objects. See “Define System Objects”.

System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

1. Create a System object to be used in your model. See “Define New Kinds of System Objects for Use in Simulink” on page 40-17 for information.
2. Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 40-22
3. Add the System object to your model using the `MATLAB System` block. See “Add System Objects to Your Simulink Model” on page 40-23 for information.
4. Add other Simulink blocks as needed and connect the blocks to construct your system.
5. Run the system

System Objects in MATLAB Code Generation

System Objects in Generated Code

You can generate C/C++ code in MATLAB from your system that contains System objects by using MATLAB Coder. You can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms.

System Objects Code with Persistent Objects for Code Generation

This example shows how to use System objects to make MATLAB code suitable for code generation. The example highlights key factors to consider, such as passing property values and using extrinsic functions. It also shows that by using persistent objects, the object states are maintained between calls.

```
function w = lmssystem(x, d)
% LMSSYSTEMIDENTIFICATION System identification using
% LMS adaptive filter
% #codegen

    % Declare System objects as persistent
    persistent hlms;

    % Initialize persistent System objects only once.
    % Do this with 'if isempty(persistent variable).'
    % This condition will be false after the first time.

    if isempty(hlms)
        % Create LMS adaptive filter used for system
        % identification. Pass property value arguments
        % as constructor arguments. Property values must
        % be constants during compile time.
```

```
        hlms = dsp.LMSFilter(11,'StepSize',0.01);
    end

    [~,~,w] = step(hlms,x,d);      % Filter weights
end
```

This example shows how to compile the `lmssystem` function and produce a MEX file with the same name in the current directory.

```
% LMSSYSTEMIDENTIFICATION System identification using
% LMS adaptive filter

coefs = fir1(10,.25);
hfilt = dsp.FIRFilter('Numerator', coefs);

x = randn(1000,1);                  % Input signal
hSrc = dsp.SignalSource(x,100);     % Use x as input-signal with
                                    % 100 samples per frame

% Generate code for lmssystem
codegen lmssystem -args {ones(100,1),ones(100,1)}

while ~isDone(hSrc)
    in = step(hSrc);
    d  = step(hfilt,in) + 0.01*randn(100,1);  % Desired signal
    w  = lmssystem_mex(in,d);           % Call generated mex file
    stem([coefs.',w]);
end
```

For another detailed code generation example, see "Generate Code for MATLAB Handle Classes and System Objects" in the MATLAB Coder product documentation.

Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty( )`.
- Set arguments to System object constructors as compile-time constants.

- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

Inputs and Outputs

- System objects accept a maximum of 32 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

Note: Variable-size properties in `MATLAB Function` block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

- Do not set System objects to become outputs from the `MATLAB Function` block.
- Do not use the Save and Restore Simulation State as SimState option for any System object in a `MATLAB Function` block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
  - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
  - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the

return argument from an object property, that object property must have the `Nontunable` attribute.

- Objects cannot be used as default values for properties.

Global Variables

- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the `MATLAB System` block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

  ```
  f = coder.MEXConfig;
  f.GlobalSyncMethod = 'NoSync'
  ```
  Then, include `'-config f'` in your `codegen` command.

Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define,

  Code generation support is available only for these methods:
  - `getDiscreteStateImpl`
  - `getNumInputsImpl`
  - `getNumOutputsImpl`
  - `infoImpl`
  - `isDoneImpl`
  - `isInputDirectFeedThroughImpl`

  - `outputImpl`
  - `processTunedPropertiesImpl`
  - `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
  - `resetImpl`
  - `setupImpl`
  - `stepImpl`
  - `updateImpl`
  - `validateInputsImpl`
  - `validatePropertiesImpl`
- Code generation support for using dot notation depends on whether the System object is predefined in the software or is one that you defined.
  - For System objects that are predefined in the software, you cannot use dot notation to call methods.
  - For System objects that you define, you can use dot notation or function call notation, with the System object as first argument, to call methods.

System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See “Getting Started with MATLAB Coder” and “MATLAB Classes” for more information.

Note: Most, but not all, System objects support code generation. Refer to the particular object’s reference page for information.

System Objects in the MATLAB Function Block

Using the `MATLAB Function` block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation

than do most associated blocks. For more information, see “What Is a MATLAB Function Block?” on page 39-5 in the Simulink documentation.

System Objects in the MATLAB System Block

Using the `MATLAB System` block, you can include in a Simulink model individual System objects that you create with a class definition file. The model can then generate embeddable code. For more information, see “MATLAB System Block” on page 42-2 in the Simulink documentation.

System Objects and MATLAB Compiler Software

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

System Objects Methods That Support Code Generation

In this section...
“Code Generation Supported System Objects Methods” on page 40-11
“Simulation-Only System Objects Methods” on page 40-11

Code Generation Supported System Objects Methods

Only the following methods are supported in code generation.

- getDiscreteStateImpl
- getNumInputsImpl
- getNumOutputsImpl
- isDoneImpl
- infoImpl
- isInputDirectFeedthroughImpl
- outputImpl
- processTunedPropertiesImpl
- releaseImpl — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
- resetImpl
- setupImpl
- stepImpl
- updateImpl
- validateInputsImpl
- validatePropertiesImpl

Simulation-Only System Objects Methods

The following methods are for simulation only and do not support code generation.

- getDiscreteStateSpecificationImpl
- getHeaderImpl

- getInputNamesImpl
- getIconImpl
- getOutputDataTypeImpl
- getOutputNamesImpl
- getOutputSizeImpl
- getPropertyGroupsImpl
- isInactivePropertyImpl
- isOutputComplexImpl
- loadObjectImpl
- propagatedInputComplexity
- propagatedInputDataType
- propagatedInputFixedSize
- propagatedInputSize
- saveObjectImpl
- supportsMultipleInstanceImpl

System Objects in Simulink

In this section...
“System Objects in the MATLAB Function Block” on page 40-13
“System Objects in the MATLAB System Block” on page 40-13

System Objects in the MATLAB Function Block

You can include System object code in Simulink models using the `MATLAB Function` block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

System Objects in the MATLAB System Block

You can include individual System objects that you create with a class definition file into Simulink using the `MATLAB System` block. This provides one way to add your own algorithm blocks into your Simulink models. For information, see “System Object Integration” in the Simulink documentation.

System Object Methods

In this section...
“What Are System Object Methods?” on page 40-14
“The Step Method” on page 40-14
“Common Methods” on page 40-15

What Are System Object Methods?

After you create a System object, you use various object methods to process data or obtain information from or about the object. All methods that are applicable to an object are described in the reference pages for that object. System object method names begin with a lowercase letter and class and property names begin with an uppercase letter. The syntax for using methods is `<method>(<handle>)`, such as `step(H)`, plus possible extra input arguments.

System objects use a minimum of two commands to process data—a constructor to create the object and the step method to run data through the object. This separation of declaration from execution lets you create multiple, persistent, reusable objects, each with different settings. Using this approach avoids repeated input validation and verification, allows for easy use within a programming loop, and improves overall performance. In contrast, MATLAB functions must validate parameters every time you call the function.

These advantages make System objects particularly well suited for processing streaming data, where segments of a continuous data stream are processed iteratively. This ability to process streaming data provides the advantage of not having to hold large amounts of data in memory. Use of streaming data also allows you to use simplified programs that use loops efficiently.

The Step Method

The `step` method is the key System object method. You use `step` to process data using the algorithm defined by that object. The `step` method performs other important tasks related to data processing, such as initialization and handling object states. Every System object has its own customized `step` method, which is described in detail on the `step` reference page for that object. For more information about the step method and other available methods, see the descriptions in “Common Methods” on page 40-15.

Common Methods

All System objects support the following methods, each of which is described in a method reference page associated with the particular object. In cases where a method is not applicable to a particular object, calling that method has no effect on the object.

Method	Description
`step`	Processes data using the algorithm defined by the object. As part of this processing, it initializes needed resources, returns outputs, and updates the object states. After you call the `step` method, you cannot change any input specifications (i.e., dimensions, data type, complexity). During execution, you can change only tunable properties. The `step` method returns regular MATLAB variables. Example: `Y = step(H,X)`
`release`	Releases any special resources allocated by the object, such as file handles and device drivers, and unlocks the object. For System objects, use the `release` method instead of a destructor.
`reset`	Resets the internal states of a locked object to the initial values for that object and leaves the object locked
`getNumInputs`	Returns the number of inputs (excluding the object itself) expected by the `step` method. This number varies for an object depending on whether any properties enable additional inputs.
`getNumOutputs`	Returns the number of outputs expected from the `step` method. This number varies for an object depending on whether any properties enable additional outputs.
`getDiscreteState`	Returns the discrete states of the object in a structure. If the object is unlocked (when the object is first created and before you have run the `step` method on it or after you have released the object), the states are empty. If the object has no discrete states, `getDiscreteState` returns an empty structure.
`clone`	Creates another object of the same type with the same property values
`isLocked`	Returns a logical value indicating whether the object is locked.

Method	Description
`isDone`	Applies to source objects only. Returns a logical value indicating whether the step method has reached the end of the data file. If a particular object does not have end-of-data capability, this method value returns `false`.
`info`	Returns a structure containing characteristic information about the object. The fields of this structure vary depending on the object. If a particular object does not have characteristic information, the structure is empty.

For a complete list of methods for writing new System objects, see “System Objects Methods for Defining New Objects” on page 41-3.

System Design in Simulink Using System Objects

Define New Kinds of System Objects for Use in Simulink

- "Define System Object with Block Customizations" on page 40-17
- "Define System Object with Nondirect Feedthrough" on page 40-20

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See "System Object Integration" in the Simulink documentation.

Define System Object with Block Customizations

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and is similar to the System Identification Using MATLAB System Blocks Simulink example.

This example shows how to create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog appearance.

Note: Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink `MATLAB System` block. You edit the template file, using it as guideline, to create your own System object.

On the first line of the class definition file, specify the name of your System object and subclass from both `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate `CustomIcon` methods to define the appearance of the `MATLAB System` block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System &...
      matlab.system.mixin.CustomIcon
   % lmsSysObj Least mean squares (LMS) adaptive filtering.
   % #codegen

   properties
      % Mu Step size
      Mu = 0.005;
   end

   properties (Nontunable)
      % Weights  Filter weights
      Weights = 0;
      % N  Number of filter weights
      N = 32;
   end
```

```
properties (DiscreteState)
   X;
   H;
end

methods (Access = protected)
   function setupImpl(obj)
      obj.X = zeros(obj.N,1);
      obj.H = zeros(obj.N,1);
   end

   function [y, e_norm] = stepImpl(obj,d,u)
      tmp = obj.X(1:obj.N-1);
      obj.X(2:obj.N,1) = tmp;
      obj.X(1,1) = u;
      y = obj.X'*obj.H;
      e = d-y;
      obj.H = obj.H + obj.Mu*e*obj.X;
      e_norm = norm(obj.Weights'-obj.H);
   end

   function resetImpl(obj)
      obj.X = zeros(obj.N,1);
      obj.H = zeros(obj.N,1);
   end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header(...
           'lmsSysObj', ...
           'Title', 'LMS Adaptive Filter');
   end

   function groups = getPropertyGroupsImpl
      upperGroup = matlab.system.display.SectionGroup(...
           'Title','General',...
           'PropertyList',{'Mu'});

      lowerGroup = matlab.system.display.SectionGroup(...
           'Title','Coefficients', ...
           'PropertyList',{'Weights','N'});
```

```
            groups = [upperGroup,lowerGroup];
        end
    end

    methods (Access = protected)
        function icon = getIconImpl(~)
            icon = sprintf('LMS Adaptive\nFilter');
        end
        function [in1name, in2name] = getInputNamesImpl(~)
            in1name = 'Desired';
            in2name = 'Actual';
        end
        function [out1name, out2name] = getOutputNamesImpl(~)
            out1name = 'Output';
            out2name = 'EstError';
        end
    end
end
```

Define System Object with Nondirect Feedthrough

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops. It is similar to the System Identification Using MATLAB System Blocks Simulink example. For information on feedback loops, see “Use System Objects in Feedback Loops” on page 42-14.

This example shows how to create a class definition text file to define your System object. The code in this example creates an integer delay and includes customizations to the block icon. It implements a System object that you can use for nondirect feedthrough.

On the first line of the class definition file, subclass from `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon. The `Nondirect` mixin enables the methods that let you specify how the block is updated and what it outputs.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl`

methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object's properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following `Nondirect` mixin class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block's internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System &...
     matlab.system.mixin.Nondirect &...
     matlab.system.mixin.CustomIcon
   % intDelaySysObj Delay input by specified number of samples.
   % #codegen

   properties
      % InitialOutput Initial output
      InitialOutput = 0;
   end

   properties (Nontunable)
      % NumDelays Number of delays
      NumDelays = 1;
   end

   properties (DiscreteState)
      PreviousInput;
   end
```

```
    methods (Access = protected)
        function setupImpl(obj, ~)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function [y] = outputImpl(obj, ~)
            % Output does not directly depend on input
            y = obj.PreviousInput(end);
        end

        function updateImpl(obj, u)
            obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
        end

        function flag = isInputDirectFeedthroughImpl(~,~)
            flag = false;
        end

        function validatePropertiesImpl(obj)
            if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
                error('Number of delays must be positive non-zero scalar value.');
            end
            if (numel(obj.InitialOutput)>1)
                error('Initial output must be scalar value.');
            end
        end

        function resetImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function icon = getIconImpl(~)
            icon = sprintf('Integer\nDelay');
        end
    end
end
```

Test New System Objects in MATLAB

1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.

```
s = lmsSysObj;
```

2 Run the step method on the object multiple times with different inputs. This tests for syntax errors and other possible issues before you add it to Simulink. For example,

```
desired = 0;
actual = 0.2;
step(s,desired,actual);
```

Add System Objects to Your Simulink Model

1 Add your System objects to your Simulink model by using the `MATLAB System` block as described in "Mapping System Objects to Block Dialog Box" on page 42-19.
2 Add other Simulink blocks, connect them, and configure any needed parameters to complete your model as described in the Simulink documentation. See the System Identification for an FIR System Using MATLAB System Blocks Simulink example.
3 Run your model in the same way you run any Simulink model.

- getOutputSizeImpl
- isInputSizeLockedImpl
- getPropertyGroupsImpl
- getSimulateUsingImpl
- isDoneImpl
- infoImpl
- isInactivePropertyImpl
- isInputDirectFeedthroughImpl
- isOutputComplexImpl
- isOutputFixedSizeImpl
- loadObjectImpl
- outputImpl
- processTunedPropertiesImpl
- propagatedInputComplexity
- propagatedInputDataType
- propagatedInputFixedSize
- propagatedInputSize
- releaseImpl

- resetImpl
- saveObjectImpl
- setProperties
- setupImpl
- showSimulateUsingImpl
- stepImpl
- supportsMultipleInstanceImpl
- updateImpl
- validateInputsImpl
- validatePropertiesImpl

Define Basic System Objects

This example shows how to create a basic System object that increments a number by one. The class definition file used in the example contains the minimum elements required to define a System object.

Create System Object

You can create and edit a MAT-file or use the MATLAB Editor to create your System object. This example describes how to use the **New** menu in the MATLAB Editor.

In MATLAB, on the Editor tab, select **New** > **System Object** > **Basic**. A simple System object template opens.

Subclass your object from `matlab.System`. Replace `Untitled` with `AddOne` in the first line of your file.

```
classdef AddOne < matlab.System
```

Save the file and name it `AddOne.m`.

Define Algorithm

The `stepImpl` method contains the algorithm to execute when you call the `step` method on your object. Define this method so that it contains the actions you want the System object to perform.

1. In the basic System object you created, inspect the `stepImpl` method template.

   ```
   methods (Access = protected)
      function y = stepImpl(obj,u)
         % Implement algorithm. Calculate y as a function of input u and
         % discrete states.
         y = u;
      end
   end
   ```

   The `stepImpl` method access is always set to `protected` because it is an internal method that users do not directly call or run.

   All methods, except static methods, expect the System object handle as the first input argument. The default value, inserted by MATLAB Editor, is `obj`. You can use any name for your System object handle.

By default, the number of inputs and outputs are both 1. Inputs and outputs can be added using **Inputs/Outputs**. If you use variable number of inputs or outputs, insert the appropriate `getNumInputsImpl` or `getNumOutputsImpl` method.

Alternatively, if you create your System object by editing a MAT-file, you can add the `stepImpl` method using **Insert Method** > **Implement algorithm**.

2 Change the computation in the y function to add 1 to the value of `u`.

```
methods (Access = protected)

    function y = stepImpl(~,u)
      y = u + 1;
    end
```

Note: Instead of passing in the object handle, you can use the tilde (~) to indicate that the object handle is not used in the function. Using the tilde instead of an object handle prevents warnings about unused variables.

3 Remove the additional, unused methods that are included by default in the basic template. Alternatively, you can modify these methods to add more System object actions and properties. You can also make no changes, and the System object still operates as intended.

The class definition file now has all the code necessary for this System object.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value one greater than the input value

  % All methods occur inside a methods declaration.
  % The stepImpl method has protected access
  methods (Access = protected)

    function y = stepImpl(~,u)
      y = u + 1;
    end
  end
end
```

Related Examples

- “Change Number of Step Inputs or Outputs” on page 41-8

Change Number of Step Inputs or Outputs

This example shows how to specify two inputs and two outputs for the `step` method.

If you specify the inputs and outputs to the `stepImpl` method, you do not need to specify the `getNumInputsImpl` and `getNumOutputsImpl` methods. If you have a variable number of inputs or outputs (using `varargin` or `varargout`), include the `getNumInputsImpl` or `getNumOutputsImpl` method, respectively, in your class definition file.

Note: You should only use `getNumInputsImpl` or `getNumOutputsImpl` methods to change the number of System object inputs or outputs. Do not use any other handle objects within a System object to change the number of inputs or outputs.

You always set the `getNumInputsImpl` and `getNumOutputsImpl` methods access to `protected` because they are internal methods that users do not directly call or run.

Update the Algorithm for Multiple Inputs and Outputs

Update the `stepImpl` method to specify two inputs and two outputs. You do not need to implement associated `getNumInputsImpl` or `getNumOutputsImpl` methods.

```
methods (Access = protected)
   function [y1,y2] = stepImpl(~,x1,x2)
      y1 = x1 + 1
      y2 = x2 + 1;
   end
end
```

Update the Algorithm and Associated Methods

Update the `stepImpl` method to use `varargin` and `varargout`. In this case, you must implement the associated `getNumInputsImpl` and `getNumOutputsImpl` methods to specify two or three inputs and outputs.

```
methods (Access = protected)
   function varargout = stepImpl(obj,varargin)
      varargout{1} = varargin{1}+1;
      varargout{2} = varargin{2}+1;
      if (obj.numInputsOutputs == 3)
         varargout{3} = varargin{3}+1;
```

```
      end
   end

   function validatePropertiesImpl(obj)
      if ~((obj.numInputsOutputs == 2) ||...
           (obj.numInputsOutputs == 3))
         error('Only 2 or 3 input and outputs allowed.');
      end
   end

   function numIn = getNumInputsImpl(obj)
      numIn = 3;
      if (obj.numInputsOutputs == 2)
         numIn = 2;
      end
   end

   function numOut = getNumOutputsImpl(obj)
      numOut = 3;
      if (obj.numInputsOutputs == 2)
         numOut = 2;
      end
   end
end
```

Use this syntax to run the algorithm with two inputs and two outputs.

```
x1 = 3;
x2 = 7;
[y1,y2] = step(AddOne,x1,x2);
```

To change the number of inputs or outputs, you must release the object before rerunning it.

```
release(AddOne)
x1 = 3;
x2 = 7;
x3 = 10
[y1,y2,y3] = step(AddOne,x1,x2,x3);
```

Complete Class Definition File with Multiple Inputs and Outputs

```
 classdef AddOne < matlab.System
% ADDONE Compute output values one greater than the input values
```

```
% This property is nontunable and cannot be changed
% after the setup or step method has been called.
properties (Nontunable)
   numInputsOutputs = 3;   % Default value
  end

% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)
   function varargout = stepImpl(obj,varargin)
      if (obj.numInputsOutputs == 2)
         varargout{1} = varargin{1}+1;
         varargout{2} = varargin{2}+1;
      else
         varargout{1} = varargin{1}+1;
         varargout{2} = varargin{2}+1;
         varargout{3} = varargin{3}+1;
      end
   end

   function validatePropertiesImpl(obj)
      if ~((obj.numInputsOutputs == 2) ||...
           (obj.numInputsOutputs == 3))
         error('Only 2 or 3 input and outputs allowed.');
      end
   end

   function numIn = getNumInputsImpl(obj)
      numIn = 3;
      if (obj.numInputsOutputs == 2)
         numIn = 2;
      end
   end

   function numOut = getNumOutputsImpl(obj)
      numOut = 3;
      if (obj.numInputsOutputs == 2)
         numOut = 2;
      end
   end
end
```

```
end
```

- “System Object Input Arguments and ~ in Code Examples” on page 41-97

Specify System Block Input and Output Names

This example shows how to specify the names of the input and output ports of a System object–based block implemented using a `MATLAB System` block.

Define Input and Output Names

This example shows how to use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as "source data" and the output port as "count."

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty strings.

```
methods (Access = protected)
   function inputName = getInputNamesImpl(~)
          inputName = 'source data';
   end

   function outputName = getOutputNamesImpl(~)
          outputName = 'count';
   end
end
```

Complete Class Definition File with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

   % MyCounter Count values above a threshold

    properties
       Threshold = 1
    end
    properties (DiscreteState)
       Count
    end

    methods
       function obj = MyCounter(varargin)
          setProperties (obj,nargin,varargin{:});
       end
    end
```

```
    methods (Access = protected)
       function setupImpl(obj)
          obj.Count = 0;
       end
       function resetImpl(obj)
          obj.Count = 0;
       end
       function y = stepImpl(obj,u)
          if (u > obj.Threshold)
             obj.Count = obj.Count + 1;
          end
          y = obj.Count;
       end
       function inputName = getInputNamesImpl(~)
          inputName = 'source data';
       end
       function outputName = getOutputNamesImpl(~)
          outputName = 'count';
       end
    end
end
```

Validate Property and Input Values

This example shows how to verify that the user's inputs and property values are valid.

Validate Properties

This example shows how to validate the value of a single property using `set.`*`PropertyName`* syntax. In this case, the *`PropertyName`* is `Increment`.

```
methods
   % Validate the properties of the object
   function set.Increment(obj,val)
       if val >= 10
         error('The increment value must be less than 10');
       end
       obj.Increment = val;
   end
 end
```

This example shows how to validate the value of two interdependent properties using the `validatePropertiesImpl` method. In this case, the `UseIncrement` property value must be `true` and the `WrapValue` property value must be less than the `Increment` property value.

```
methods (Access = protected)
   function validatePropertiesImpl(obj)
       if obj.UseIncrement && obj.WrapValue > obj.Increment
         error('Wrap value must be less than increment value');
       end
   end
end
```

Validate Inputs

This example shows how to validate that the first input is a numeric value.

```
methods (Access = protected)
   function validateInputsImpl(~,x)
      if ~isnumeric(x)
         error('Input must be numeric');
      end
   end
```

```
end
```

Complete Class Definition File with Property and Input Validation

```
classdef AddOne < matlab.System
% ADDONE Compute an output value by incrementing the input value

  % All properties occur inside a properties declaration.
  % These properties have public access (the default)
  properties (Logical)
    UseIncrement = true
  end

  properties (PositiveInteger)
    Increment = 1
    WrapValue = 10
  end

  methods
    % Validate the properties of the object
    function set.Increment(obj,val)
        if val >= 10
          error('The increment value must be less than 10');
        end
        obj.Increment = val;
    end
  end

  methods (Access = protected)
    function validatePropertiesImpl(obj)
        if obj.UseIncrement && obj.WrapValue > obj.Increment
          error('Wrap value must be less than increment value');
        end
    end

    % Validate the inputs to the object
    function validateInputsImpl(~,x)
        if ~isnumeric(x)
          error('Input must be numeric');
        end
    end

    function out = stepImpl(obj,in)
      if obj.UseIncrement
        out = in + obj.Increment;
```

```
      else
        out = in + 1;
      end
    end
  end
end
```

Initialize Properties and Setup One-Time Calculations

This example shows how to write code to initialize and set up a System object.

In this example, you allocate file resources by opening the file so the System object can write to that file. You do these initialization tasks one time during setup, rather than every time you call the step method.

Define Public Properties to Initialize

In this example, you define the public `Filename` property and specify the value of that property as the nontunable string, `default.bin`. Users cannot change *nontunable* properties after the `setup` method has been called. Refer to the Methods Timing section for more information.

```
properties (Nontunable)
  Filename = 'default.bin'
end
```

Define Private Properties to Initialize

Users cannot access *private* properties directly, but only through methods of the System object. In this example, you define the `pFileID` property as a private property. You also define this property as *hidden* to indicate it is an internal property that never displays to the user.

```
properties (Hidden,Access = private)
  pFileID;
end
```

Define Setup

You use the `setupImpl` method to perform setup and initialization tasks. You should include code in the `setupImpl` method that you want to execute one time only. The `setupImpl` method is called once during the first call to the `step` method. In this example, you allocate file resources by opening the file for writing binary data.

```
methods
  function setupImpl(obj)
    obj.pFileID = fopen(obj.Filename,'wb');
    if obj.pFileID < 0
       error('Opening the file failed');
```

```
    end
  end
end
```

Although not part of setup, you should close files when your code is done using them. You use the `releaseImpl` method to release resources.

Complete Class Definition File with Initialization and Setup

```
classdef MyFile < matlab.System
% MyFile write numbers to a file

    % These properties are nontunable. They cannot be changed
    % after the setup or step  method has been called.
    properties (Nontunable)
        Filename = 'default.bin' % the name of the file to create
    end

    % These properties are private. Customers can only access
    % these properties through methods on this object
    properties (Hidden,Access = private)
        pFileID; % The identifier of the file to open
    end

    methods (Access = protected)
        % In setup allocate any resources, which in this case
        % means opening the file.
        function setupImpl(obj)
            obj.pFileID = fopen(obj.Filename,'wb');
            if obj.pFileID < 0
                error('Opening the file failed');
            end
        end

        % This System object™ writes the input to the file.
        function stepImpl(obj,data)
            fwrite(obj.pFileID,data);
        end

        % Use release to close the file to prevent the
        % file handle from being left open.
        function releaseImpl(obj)
            fclose(obj.pFileID);
        end
    end
```

```
end
```

Set Property Values at Construction Time

This example shows how to define a System object constructor and allow it to accept name-value property pairs as input.

Set Properties to Use Name-Value Pair Input

Define the System object constructor, which is a method that has the same name as the class (`MyFile` in this example). Within that method, you use the `setProperties` method to make all public properties available for input when the user constructs the object. `nargin` is a MATLAB function that determines the number of input arguments. `varargin` indicates all of the object's public properties.

```
methods
   function obj = MyFile(varargin)
      setProperties(obj,nargin,varargin{:});
   end
end
```

Complete Class Definition File with Constructor Setup

```
classdef MyFile < matlab.System
% MyFile write numbers to a file

    % These properties are nontunable. They cannot be changed
    % after the setup or step method has been called.
    properties (Nontunable)
        Filename ='default.bin' % the name of the file to create
        Access = 'wb' % The file access string (write, binary)
    end

    % These properties are private. Customers can only access
    % these properties through methods on this object
    properties (Hidden,Access = private)
        pFileID; % The identifier of the file to open
    end

    methods
        % You call setProperties in the constructor to let
        % a user specify public properties of object as
        % name-value pairs.
        function obj = MyFile(varargin)
          setProperties(obj,nargin,varargin{:});
        end
```

```
    end

    methods (Access = protected)
        % In setup allocate any resources, which in this case is
        % opening the file.
        function setupImpl(obj)
            obj.pFileID = fopen(obj.Filename,obj.Access);
            if obj.pFileID < 0
                error('Opening the file failed');
            end
        end

        % This System object™ writes the input to the file.
        function stepImpl(obj,data)
            fwrite(obj.pFileID,data);
        end

        % Use release to close the file to prevent the
        % file handle from being left open.
        function releaseImpl(obj)
            fclose(obj.pFileID);
        end
    end
end
```

Reset Algorithm State

This example shows how to reset an object state.

Reset Counter to Zero

`pCount` is an internal counter property of the System object `obj`. The user calls the `reset` method on the locked object, which calls the `resetImpl` method. In this example , `pCount` resets to 0.

Note: When resetting an object's state, make sure you reset the size, complexity, and data type correctly.

```
methods (Access = protected)
   function resetImpl(obj)
      obj.pCount = 0;
   end
end
```

Complete Class Definition File with State Reset

```
classdef Counter < matlab.System
% Counter System object™ that increments a counter

   properties (Access = private)
      pCount
   end

   methods (Access = protected)
      % In step, increment the counter and return
      % its value as an output
      function c = stepImpl(obj)
          obj.pCount = obj.pCount + 1;
          c = obj.pCount;
      end

      % Reset the counter to zero.
      function resetImpl(obj)
         obj.pCount = 0;
      end
   end
```

```
end
```

Define Property Attributes

This example shows how to specify property attributes.

Property attributes, which add details to a property, provide a layer of control to your properties. In addition to the MATLAB property attributes, System objects can use these three additional attributes—`nontunable`, `logical`, and `positiveInteger`. To specify multiple attributes, separate them with commas.

Specify Property as Nontunable

Use the *nontunable* attribute for a property when the algorithm depends on the value being constant once data processing starts. Defining a property as nontunable may improve the efficiency of your algorithm by removing the need to check for or react to values that change. For code generation, defining a property as nontunable allows the memory associated with that property to be optimized. You should define all properties that affect the number of input or output ports as nontunable.

System object users cannot change nontunable properties after the `setup` or `step` method has been called. In this example, you define the `InitialValue` property, and set its value to 0.

```
properties (Nontunable)
   InitialValue = 0;
end
```

Specify Property as Logical

Logical properties have the value, `true` or `false`. System object users can enter `1` or `0` or any value that can be converted to a logical. The value, however, displays as `true` or `false`. You can use sparse logical values, but they must be scalar values. In this example, the `Increment` property indicates whether to increase the counter. By default, `Increment` is tunable property. The following restrictions apply to a property with the `Logical` attribute,

- Cannot also be `Dependent` or `PositiveInteger`
- Default value must be `true` or `false`. You cannot use `1` or `0` as a default value.

```
properties (Logical)
   Increment = true
end
```

Specify Property as Positive Integer

In this example, the private property `MaxValue` is constrained to accept only real, positive integers. You cannot use sparse values. The following restriction applies to a property with the `PositiveInteger` attribute,

- Cannot also be `Dependent` or `Logical`

```
properties (PositiveInteger)
   MaxValue
end
```

Specify Property as DiscreteState

If your algorithm uses properties that hold state, you can assign those properties the `DiscreteState` attribute . Properties with this attribute display their state values when users call `getDiscreteStateImpl` via the `getDiscreteState` method. The following restrictions apply to a property with the `DiscreteState` attribute,

- Numeric, logical, or fi value, but not a scaled double fi value
- Does not have any of these attributes: `Nontunable`, `Dependent`, `Abstract`, `Constant`, or `Transient`.
- No default value
- Not publicly settable
- `GetAccess = Public` by default
- Value set only using the `setupImpl` method or when the System object is locked during `resetImpl` or `stepImpl`

In this example, you define the `Count` property.

```
properties (DiscreteState)
   Count;
end
```

Complete Class Definition File with Property Attributes

```
classdef Counter < matlab.System
% Counter Increment a counter to a maximum value

  % These properties are nontunable. They cannot be changed
  % after the setup or step method has been called.
  properties (Nontunable)
```

```
    % The inital value of the counter
    InitialValue = 0
end
properties (Nontunable, PositiveInteger)
    % The maximum value of the counter
    MaxValue = 3
end

properties (Logical)
    % Whether to increment the counter
    Increment = true
end

properties (DiscreteState)
    % Count state variable
    Count
end

methods (Access = protected)
    % In step, increment the counter and return its value
    % as an output

    function c = stepImpl(obj)
        if obj.Increment && (obj.Count < obj.MaxValue)
            obj.Count = obj.Count + 1;
        else
            disp(['Max count, ' num2str(obj.MaxValue) ',reached'])
        end
        c = obj.Count;
    end

    % Setup the Count state variable
    function setupImpl(obj)
        obj.Count = 0;
    end

    % Reset the counter to one.
    function resetImpl(obj)
        obj.Count = obj.InitialValue;
    end
end
```

```
end
```

Hide Inactive Properties

This example shows how to hide the display of a property that is not active for a particular object configuration.

Hide an inactive property

You use the `isInactivePropertyImpl` method to hide a property from displaying. If the `isInactiveProperty` method returns `true` to the property you pass in, then that property does not display.

```
methods (Access = protected)
  function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
      flag = obj.UseRandomInitialValue;
    else
      flag = false;
    end
  end
end
```

Complete Class Definition File with Hidden Inactive Property

```
classdef Counter < matlab.System
  % Counter Increment a counter

  % These properties are nontunable. They cannot be changed
  % after the setup or step method has been called.
  properties (Nontunable)
    % Allow the user to set the initial value
    UseRandomInitialValue = true
    InitialValue = 0
  end

  % The private count variable, which is tunable by default
  properties (Access = private)
    pCount
  end

  methods (Access = protected)
    % In step, increment the counter and return its value
    % as an output
    function c = stepImpl(obj)
      obj.pCount = obj.pCount + 1;
```

```
      c = obj.pCount;
    end

    % Reset the counter to either a random value or the initial
    % value.
    function resetImpl(obj)
      if obj.UseRandomInitialValue
        obj.pCount = rand();
      else
        obj.pCount = obj.InitialValue;
      end
    end

    % This method controls visibility of the object's properties
    function flag = isInactivePropertyImpl(obj,propertyName)
      if strcmp(propertyName,'InitialValue')
        flag = obj.UseRandomInitialValue;
      else
        flag = false;
      end
    end
  end
end
```

Limit Property Values to Finite String Set

This example shows how to limit a property to accept only a finite set of string values.

Specify a Set of Valid String Values

String sets use two related properties. You first specify the user-visible property name and default string value. Then, you specify the associated hidden property by appending "Set" to the property name. You must use a capital "S" in "Set."

In the "Set" property, you specify the valid string values as a cell array of the `matlab.system.Stringset` class. This example uses `Color` and `ColorSet` as the associated properties.

```
properties
   Color = 'blue'
end

properties (Hidden,Transient)
   ColorSet = matlab.system.StringSet({'red','blue','green'});
end
```

Complete Class Definition File with String Set

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ illustrates the use of StringSets

   properties
     Color = 'blue'
   end

   properties (Hidden,Transient)
     % Let them choose a color
     ColorSet = matlab.system.StringSet({'red','blue','green'});
   end

   methods (Access = protected)
     function stepImpl(obj)
         h = Whiteboard.getWhiteboard();
         plot(h, ...
           randn([2,1]),randn([2,1]), ...
           'Color',obj.Color(1));
```

```
    end
    function releaseImpl(obj)
        cla(Whiteboard.getWhiteboard());
        hold on
    end
  end

  methods (Static)
    function a = getWhiteboard()
        h = findobj('tag','whiteboard');
        if isempty(h)
          h = figure('tag','whiteboard');
          hold on
        end
        a = gca;
    end
  end
end
```

String Set System Object Example

```
%%
% Each call to step draws lines on a whiteboard

%% Construct the System object
hGreenInk = Whiteboard;
hBlueInk  = Whiteboard;

% Change the color
% Note: Press tab after typing the first single quote to
% display all enumerated values.
hGreenInk.Color = 'green';
hBlueInk.Color  = 'blue';

% Take a few steps
for i=1:3
  hGreenInk.step();
  hBlueInk.step();
end

%% Clear the whiteboard
hBlueInk.release();

%% Display System object used in this example
```

```
type('Whiteboard.m');
```

Process Tuned Properties

This example shows how to specify the action to take when a tunable property value changes during simulation.

The `processTunedPropertiesImpl` method is useful for managing actions to prevent duplication. In many cases, changing one of multiple interdependent properties causes an action. With the `processTunedPropertiesImpl` method, you can control when that action is taken so it is not repeated unnecessarily.

Control When a Lookup Table Is Generated

This example of `processTunedPropertiesImpl` causes the `pLookupTable` to be regenerated when either the `NumNotes` or `MiddleC` property changes.

```
methods  (Access = protected)
   function processTunedPropertiesImpl(obj)
      propChange = isChangedProperty(obj,obj.NumNotes)||...
         isChangedProperty(obj,obj.MiddleC)
      if propChange
         obj.pLookupTable = obj.MiddleC *...
           (1+log(1:obj.NumNotes)/log(12));
      end
    endend
```

Complete Class Definition File with Tuned Property Processing

```
classdef TuningFork < matlab.System
  % TuningFork Illustrate the processing of tuned parameters
  %

  properties
    MiddleC = 440
    NumNotes = 12
  end

  properties (Access = private)
    pLookupTable
  end

  methods (Access = protected)
    function resetImpl(obj)
      obj.MiddleC = 440;
      obj.pLookupTable = obj.MiddleC * ...
```

```
            (1+log(1:obj.NumNotes)/log(12));
        end

        function hz = stepImpl(obj,noteShift)
          % A noteShift value of 1 corresponds to obj.MiddleC
          hz = obj.pLookupTable(noteShift);
        end

        function processTunedPropertiesImpl(obj)
          propChange = isChangedProperty(obj,obj.NumNotes)||...
             isChangedProperty(obj,obj.MiddleC)
          if propChange
             obj.pLookupTable = obj.MiddleC *...
               (1+log(1:obj.NumNotes)/log(12));
          end
      end
    end
```

Release System Object Resources

This example shows how to release resources allocated and used by the System object. These resources include allocated memory, files used for reading or writing, etc.

Release Memory by Clearing the Object

This method allows you to clear the axes on the Whiteboard figure window while keeping the figure open.

```
methods
   function releaseImpl(obj)
      cla(Whiteboard.getWhiteboard());
      hold on
   end
end
```

Complete Class Definition File with Released Resources

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ shows the use of StringSets
%
   properties
     Color = 'blue'
   end

   properties (Hidden)
     % Let user choose a color
     ColorSet = matlab.system.StringSet({'red','blue','green'});
   end

   methods (Access = protected)
     function stepImpl(obj)
         h = Whiteboard.getWhiteboard();
         plot(h, ...
           randn([2,1]), randn([2,1]), ...
           'Color',obj.Color(1));
     end

     function releaseImpl(obj)
         cla(Whiteboard.getWhiteboard());
         hold on
```

```
    end
  end

  methods (Static)
    function a = getWhiteboard()
        h = findobj('tag','whiteboard');
        if isempty(h)
          h = figure('tag','whiteboard');
          hold on
        end
        a = gca;
    end
  end
end
```

Define Composite System Objects

This example shows how to define System objects that include other System objects.

This example defines a bandpass filter System object from separate highpass and lowpass filter System objects.

Store System Objects in Properties

To define a System object from other System objects, store those other objects in your class definition file as properties. In this example, the highpass and lowpass filters are the separate System objects defined in their own class-definition files.

```
properties (Access = private)
   % Properties that hold filter System objects
   pLowpass
   pHighpass
end
```

Complete Class Definition File of Bandpass Filter Composite System Object

```
classdef BandpassFIRFilter < matlab.System
% Implements a bandpass filter using a cascade of eighth-order lowpass
% and eighth-order highpass FIR filters.

    properties (Access = private)
        % Properties that hold filter System objects
        pLowpass
        pHighpass
    end

    methods (Access = protected)
        function setupImpl(obj)
            % Setup composite object from constituent objects
            obj.pLowpass = LowpassFIRFilter;
            obj.pHighpass = HighpassFIRFilter;
        end

        function yHigh = stepImpl(obj,u)
            yLow = step(obj.pLowpass,u);
            yHigh = step(obj.pHighpass,yLow);
        end

        function resetImpl(obj)
```

```
            reset(obj.pLowpass);
            reset(obj.pHighpass);
        end
    end
end
```

Class Definition File for Lowpass FIR Component of Bandpass Filter

```
classdef LowpassFIRFilter < matlab.System
% Implements eighth-order lowpass FIR filter with 0.6pi cutoff

    properties (Nontunable)
        % Filter coefficients
        Numerator = [0.006,-0.0133,-0.05,0.26,0.6,0.26,-0.05,-0.0133,0.006];
    end

    properties (DiscreteState)
        State
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
        function y = stepImpl(obj,u)
            [y,obj.State] = filter(obj.Numerator,1,u,obj.State);
        end
        function resetImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
    end
end
```

Class Definition File for Highpass FIR Component of Bandpass Filter

```
classdef HighpassFIRFilter < matlab.System
% Implements eighth-order highpass FIR filter with 0.4pi cutoff

    properties (Nontunable)
        % Filter coefficients

Define Finite Source Objects

This example shows how to define a System object that performs a specific number of steps or specific number of reads from a file.

Use the FiniteSource Class and Specify End of the Source

1 Subclass from finite source class.

```
classdef RunTwice < matlab.System & ...
   matlab.system.mixin.FiniteSource
```

2 Specify the end of the source with the `isDoneImpl` method. In this example, the source has two iterations.

```
methods (Access = protected)
  function bDone = isDoneImpl(obj)
     bDone = obj.NumSteps==2
  end
```

Complete Class Definition File with Finite Source

```
classdef RunTwice < matlab.System & ...
    matlab.system.mixin.FiniteSource
  % RunTwice System object that runs exactly two times
  %
  properties (Access = private)
    NumSteps
  end

  methods (Access = protected)
    function resetImpl(obj)
      obj.NumSteps = 0;
    end

    function y = stepImpl(obj)
      if ~obj.isDone()
        obj.NumSteps = obj.NumSteps + 1;
        y = obj.NumSteps;
      else
        y = 0;
      end
    end

    function bDone = isDoneImpl(obj)
```

```
      bDone = obj.NumSteps==2;
    end
  end
end
```

Save System Object

This example shows how to save a System object.

Save System Object and Child Object

Define a `saveObjectImpl` method to specify that more than just public properties should be saved when the user saves a System object. Within this method, use the default `saveObjectImpl@matlab.System` to save public properties to the struct, `s`. Use the `saveObject` method to save child objects. Save protected and dependent properties, and finally, if the object is locked, save the object's state.

```
methods (Access = protected)
  function s = saveObjectImpl(obj)
    s = saveObjectImpl@matlab.System(obj);
    s.child = matlab.System.saveObject(obj.child);
    s.protectedprop = obj.protectedprop;
    s.pdependentprop = obj.pdependentprop;
    if isLocked(obj)
      s.state = obj.state;
    end
  end
end
```

Complete Class Definition Files with Save and Load

The `Counter` class definition file sets up an object with a count property. This counter is used in the `MySaveLoader` class definition file to count the number of child objects.

```
classdef Counter < matlab.System
  properties(DiscreteState)
    Count
  end
  methods (Access=protected)
    function setupImpl(obj, ~)
      obj.Count = 0;
    end
    function y = stepImpl(obj, u)
      if u > 0
        obj.Count = obj.Count + 1;
      end
      y = obj.Count;
    end
```

```
  end
end

classdef MySaveLoader < matlab.System

  properties (Access = private)
    child
    pdependentprop = 1
  end

  properties (Access = protected)
    protectedprop = rand;
  end

  properties (DiscreteState = true)
    state
  end

  properties (Dependent)
    dependentprop
  end

  methods
    function obj = MySaveLoader(varargin)
      obj@matlab.System();
      setProperties(obj,nargin,varargin{:});
    end

    function set.dependentprop(obj, value)
      obj.pdependentprop = min(value, 5);
    end

    function value = get.dependentprop(obj)
      value = obj.pdependentprop;
    end
  end

  methods (Access = protected)
    function setupImpl(obj)
      obj.state = 42;
      obj.child = Counter;
    end
    function out = stepImpl(obj,in)
      obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
      out = step(obj.child, obj.state);
```

```
    end
  end

  % Serialization
  methods (Access = protected)
    function s = saveObjectImpl(obj)
      % Call the base class method
      s = saveObjectImpl@matlab.System(obj);

      % Save the child System objects
      s.child = matlab.System.saveObject(obj.child);

      % Save the protected & private properties
      s.protectedprop = obj.protectedprop;
      s.pdependentprop = obj.pdependentprop;

      % Save the state only if object locked
      if isLocked(obj)
        s.state = obj.state;
      end
    end

    function loadObjectImpl(obj,s,wasLocked)
      % Load child System objects
      obj.child = matlab.System.loadObject(s.child);

      % Load protected and private properties
      obj.protectedprop = s.protectedprop;
      obj.pdependentprop = s.pdependentprop;

      % Load the state only if object locked
      if wasLocked
        obj.state = s.state;
      end

      % Call base class method to load public properties
      loadObjectImpl@matlab.System(obj,s,wasLocked);
    end
  end
end
```

Load System Object

This example shows how to load and save a System object.

Load System Object and Child Object

Define a `loadObjectImpl` method to load a previously saved System object. Within this method, use the `matlab.System.loadObject` to load the child System object, load protected and private properties, load the state if the object is locked, and use `loadObjectImpl` from the base class to load public properties.

```
methods (Access = protected)
  function loadObjectImpl(obj,s,wasLocked)
    obj.child = matlab.System.loadObject(s.child);

    obj.protectedprop = s.protectedprop;
    obj.pdependentprop = s.pdependentprop;

    if wasLocked
      obj.state = s.state;
    end

    loadObjectImpl@matlab.System(obj,s,wasLocked);
  end
end
```

Complete Class Definition Files with Save and Load

The Counter class definition file sets up an object with a count property. This counter is used in the MySaveLoader class definition file to count the number of child objects.

```
classdef Counter < matlab.System
  properties(DiscreteState)
    Count
  end
  methods (Access=protected)
    function setupImpl(obj, ~)
      obj.Count = 0;
    end
    function y = stepImpl(obj, u)
      if u > 0
        obj.Count = obj.Count + 1;
      end
      y = obj.Count;
```

```
    end
  end
end

classdef MySaveLoader < matlab.System

  properties (Access = private)
    child
    pdependentprop = 1
  end

  properties (Access = protected)
    protectedprop = rand;
  end

  properties (DiscreteState = true)
    state
  end

  properties (Dependent)
    dependentprop
  end

  methods
    function obj = MySaveLoader(varargin)
      obj@matlab.System();
      setProperties(obj,nargin,varargin{:});
    end

    function set.dependentprop(obj, value)
      obj.pdependentprop = min(value, 5);
    end

    function value = get.dependentprop(obj)
      value = obj.pdependentprop;
    end
  end

  methods (Access = protected)
    function setupImpl(obj)
      obj.state = 42;
      obj.child = Counter;
    end
    function out = stepImpl(obj,in)
      obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
```

```
    out = step(obj.child, obj.state);
  end
end

% Serialization
methods (Access = protected)
  function s = saveObjectImpl(obj)
    % Call the base class method
    s = saveObjectImpl@matlab.System(obj);

    % Save the child System objects
    s.child = matlab.System.saveObject(obj.child);

    % Save the protected & private properties
    s.protectedprop = obj.protectedprop;
    s.pdependentprop = obj.pdependentprop;

    % Save the state only if object locked
    if isLocked(obj)
      s.state = obj.state;
    end
  end

  function loadObjectImpl(obj,s,wasLocked)
    % Load child System objects
    obj.child = matlab.System.loadObject(s.child);

    % Load protected and private properties
    obj.protectedprop = s.protectedprop;
    obj.pdependentprop = s.pdependentprop;

    % Load the state only if object locked

Define System Object Information

This example shows how to define information to display for a System object.

Define System Object Info

You can define your own `info` method to display specific information for your System object. The default `infoImpl` method returns an empty struct. This `infoImpl` method returns detailed information when the `info` method is called using `info(x,'details')` or only count information if it is called using `info(x)`.

```
methods (Access = protected)
   function s = infoImpl(obj,varargin)
      if nargin>1 && strcmp('details',varargin(1))
         s = struct('Name','Counter',...
             'Properties', struct('CurrentCount', ...
              obj.pCount,'Threshold',obj.Threshold));
      else
         s = struct('Count',obj.pCount);
      end
   end
end
```

Complete Class Definition File with InfoImpl

```
classdef Counter < matlab.System
   % Counter Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function resetImpl(obj)
         obj.Count = 0;
      end
```

```
      function y = stepImpl(obj,u)
         if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
         end
         y = obj.Count;
      end

      function s = infoImpl(obj,varargin)
         if nargin>1 && strcmp('details',varargin(1))
            s = struct('Name','Counter',...
            'Properties', struct('CurrentCount', ...
            obj.pCount,'Threshold',obj.Threshold));
         else
            s = struct('Count',obj.pCount);
      end
   end
end
```

Define MATLAB System Block Icon

This example shows how to define the block icon of a System object–based block implemented using a `MATLAB System` block.

Use the CustomIcon Class and Define the Icon

1. Subclass from custom icon class.

```
classdef MyCounter < matlab.System & ...
  matlab.system.mixin.CustomIcon
```

2. Use `getIconImpl` to specify the block icon as `New Counter` with a line break (`\n`) between the two words.

```
methods (Access = protected)
   function icon = getIconImpl(~)
      icon = sprintf('New\nCounter');
   end
end
```

Complete Class Definition File with Defined Icon

```
classdef MyCounter < matlab.System & ...
   matlab.system.mixin.CustomIcon

   % MyCounter Count values above a threshold

    properties
       Threshold = 1
    end
    properties (DiscreteState)
       Count
    end

    methods
       function obj = MyCounter(varargin)
          setProperties(obj,nargin,varargin{:});
       end
    end

    methods (Access = protected)
       function setupImpl(obj)
          obj.Count = 0;
       end
```

```
        function resetImpl(obj)
           obj.Count = 0;
        end
        function y = stepImpl(obj,u)
           if (u > obj.Threshold)
              obj.Count = obj.Count + 1;
           end
           y = obj.Count;
        end
        function icon = getIconImpl(~)
           icon = sprintf('New\nCounter');
        end
    end
end
```

Add Header to MATLAB System Block

This example shows how to add a header panel to a System object–based block implemented using a `MATLAB System` block.

Define Header Title and Text

This example shows how to use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object.

If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

You always set the `getHeaderImpl` method access to `protected` because it is an internal method that end users do not directly call or run.

```
methods (Static, Access = protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header('MyCounter',...
        'Title','My Enhanced Counter');
   end
end
```

Complete Class Definition File with Defined Header

```
 classdef MyCounter < matlab.System

   % MyCounter Count values

    properties
       Threshold = 1
    end
    properties (DiscreteState)
       Count
    end

    methods (Static, Access = protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('MyCounter',...
           'Title','My Enhanced Counter',...
           'Text', 'This counter is an enhanced version.');
      end
    end
```

```
    methods (Access = protected)
       function setupImpl(obj,u)
          obj.Count = 0;
       end
       function y = stepImpl(obj,u)
          if (u > obj.Threshold)
             obj.Count = obj.Count + 1;
          end
          y = obj.Count;
       end
       function resetImpl(obj)
          obj.Count = 0;
       end
    end
end
```

Add Data Types Tab to MATLAB System Block

This example shows how to add a Data Types tab to the `MATLAB System` block dialog box. This tab includes fixed-point data type settings.

Display Data Types Tab

This example shows how to use `matlab.system.showFiSettingsImpl` to display the Data Types tab in the `MATLAB System` block dialog.

```
methods (Static, Access = protected)
   function showTab = showFiSettingsImpl
      showTab = true;
   end
end
```

Complete Class Definition File with Data Types Tab

Use `showFiSettingsImpl` to display the Data Types tab for a System object that adds an offset to a fixed-point input.

```
classdef FiTabAddOffset < matlab.System
% FiTabAddOffset Add an offset to input

   properties
      Offset = 1;
   end

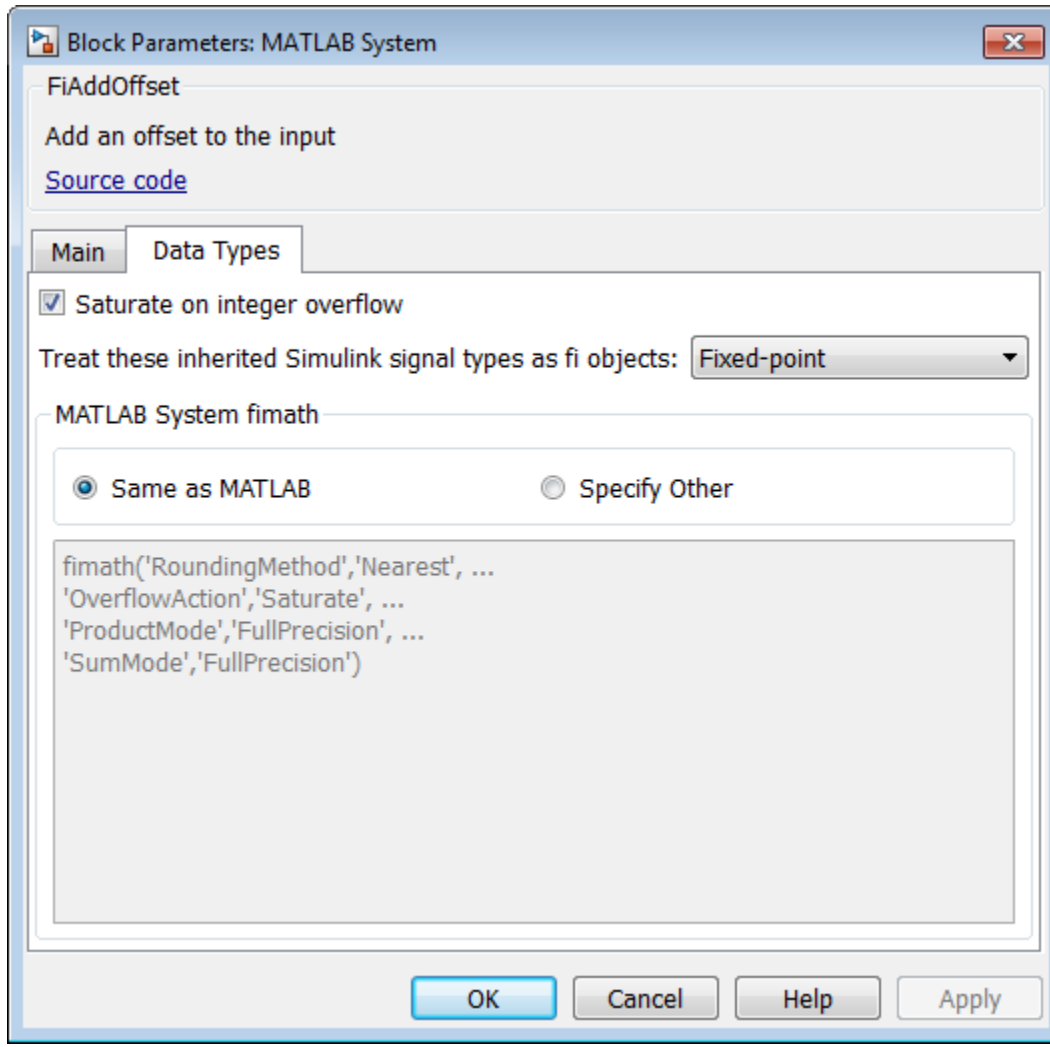
   methods
      function obj = FiTabAddOffset(varargin)
         setProperties(obj,nargin,varargin{:});
      end
   end

   methods (Access = protected)
      function y = stepImpl(~,u)
         y = u + obj.Offset;
      end
   end

   methods(Static, Access=protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('Title',...
              'Add Offset','Text','Add an offset to the input');
```

```
        end

        function isVisible = showFiSettingsImpl
            isVisible = true;
        end
    end
end
```



Add Property Groups to System Object and MATLAB System Block

This example shows how to define property sections and section groups for System object display. The sections and section groups display as panels and tabs, respectively, in the `MATLAB System` block dialog.

Define Section of Properties

This example shows how to use `matlab.system.display.Section` and `getPropertyGroupsImpl` to define two property group sections by specifying their titles and property lists.

If you do not specify a property in `getPropertyGroupsImpl`, the block does not display that property.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});
      groups = [valueGroup,thresholdGroup];
   end
end
```

Define Group of Sections

This example shows how to use `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` to define two tabs, each containing specific properties.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      upperGroup = matlab.system.display.Section(...
           'Title', 'Upper threshold', ...
           'PropertyList',{'UpperThreshold'});
      lowerGroup = matlab.system.display.Section(...
           'Title','Lower threshold', ...
           'PropertyList',{'UseLowerThreshold','LowerThreshold'});

      thresholdGroup = matlab.system.display.SectionGroup(...
```

```
            'Title', 'Parameters', ...
            'Sections',  [upperGroup,lowerGroup]);

        valuesGroup = matlab.system.display.SectionGroup(...
            'Title', 'Initial conditions', ...
            'PropertyList',  {'StartValue'});

        groups = [thresholdGroup, valuesGroup];
    end
end
```

Complete Class Definition File with Property Group and Separate Tab

```
classdef EnhancedCounter < matlab.System
    % EnhancedCounter  Count values considering thresholds

    properties
        UpperThreshold = 1;
        LowerThreshold = 0;
    end

    properties (Nontunable)
        StartValue = 0;
    end

    properties(Logical,Nontunable)
        % Count values less than lower threshold
        UseLowerThreshold = true;
    end

    properties (DiscreteState)
        Count;
    end

    methods (Static, Access = protected)
        function groups = getPropertyGroupsImpl
            upperGroup = matlab.system.display.Section(...
                'Title', 'Upper threshold', ...
                'PropertyList',{'UpperThreshold'});
            lowerGroup = matlab.system.display.Section(...
                'Title','Lower threshold', ...
                'PropertyList',{'UseLowerThreshold','LowerThreshold'});

            thresholdGroup = matlab.system.display.SectionGroup(...
                'Title', 'Parameters', ...
```

```

Control Simulation Type in MATLAB System Block

This example shows how to specify a simulation type and whether the **Simulate using** parameter appears on the Simulink `MATLAB System` block dialog box. The simulation options are `'Code generation'` and `'Interpreted mode'`.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to `'Code generation'`. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to `static` and the access for these methods to `protected`.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```
methods(Static,Access = protected)
   function simMode = getSimulateUsingImpl
       simMode = 'Interpreted execution';
    end
end
```

View the method in the complete class definition file.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

  methods(Static, Access=protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(~,obj)...
            visualize(obj),'Label','Visualize');
    end

    function simMode = getSimulateUsingImpl
      simMode = 'Interpreted execution';
    end
  end
```

```
  methods
    function obj = ActionDemo(varargin)
      setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj)
      figure;
      d = 1:obj.RampLimit;
      plot(d);
    end
   methods(Static,Access = protected)
   end
  end
end
```

Add Button to MATLAB System Block

This example shows how to add a button to the `MATLAB System` block dialog box. This button launches a figure that plots a ramp function.

Define Action for Dialog Button

This example shows how to use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the `MATLAB System` block dialog. The example also shows how to set button options and use an actionData object input to store a figure handle. This part of the code example uses the same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```
methods(Static,Access = protected)
  function group = getPropertyGroupsImpl
    group = matlab.system.display.Section(mfilename('class'));
    group.Actions = matlab.system.display.Action(@(actionData,obj)...
       visualize(obj,actionData),'Label','Visualize');
  end
end

methods
  function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
  end

  function visualize(obj,actionData)
    f = actionData.UserData;
    if isempty(f) || ~ishandle(f)
      f = figure;
      actionData.UserData = f;
    else
      figure(f); % Make figure current
    end

    d = 1:obj.RampLimit;
    plot(d);
  end
end
```

Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

  methods(Static,Access = protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(actionData,obj)...
        visualize(obj,actionData),'Label','Visualize');
    end
  end

  methods
    function obj = ActionDemo(varargin)
      setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj,actionData)
      f = actionData.UserData;
      if isempty(f) || ~ishandle(f)
        f = figure;
        actionData.UserData = f;
      else
        figure(f); % Make figure current
      end

      d = 1:obj.RampLimit;
      plot(d);
    end
  end
```

```
end
```

Specify Locked Input Size

This example shows how to specify whether the size of a System object input is locked. The size of a locked input cannot change until the System object is unlocked. Use the `step` method and run the object to lock it. Use `release` to unlock the object.

Use the `isInputSizeLockedImpl` method to specify that the input size is locked.

```
methods (Access = protected)
  function flag = isInputSizeLockedImpl(~,~)
    flag = true;
  end
end
```

View the method in the complete class definition file.

```
classdef Counter < matlab.System
  %Counter Count values above a threshold

  properties
    Threshold = 1
  end

  properties (DiscreteState)
    Count
  end

  methods
    function obj = Counter(varargin)
      setProperties(obj,nargin,varargin{:});
    end
  end

  methods (Access=protected)
    function resetImpl(obj)
      obj.Count = 0;
    end

    function y = stepImpl(obj, u1)
      if (any(u1 >= obj.Threshold))
        obj.Count = obj.Count + 1;
      end
      y = obj.Count;
    end
```

```
    function flag = isInputSizeLockedImpl(~,~)
      flag = true;
    end
  end
end
```

isInputSizeLockedImpl

Set Output Size

This example shows how to specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation.

Note: For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run step on an object, it uses the actual sizes of the inputs.
- Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
   function sizeout = getOutputSizeImpl(~)
      sizeout = [1 1];
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
```

```
function setupImpl(obj)
   obj.Count = 0;
end

function y = stepImpl(obj,u1,u2)
   % Add to count if u1 is above threshold
   % Reset if u2 is true
   if (u2)
     obj.Count = 0;
   elseif (any(u1 > obj.Threshold))
     obj.Count = obj.Count + 1;
   end
   y = obj.Count;
end

function resetImpl(obj)
   obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
   if strcmp(name,'Count')
      sz = [1 1];
      dt = 'double';
      cp = false;
   else
      error(['Error: Incorrect State Name: ', name.']);
   end
end
function dataout = getOutputDataTypeImpl(~)
   dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
   sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
   cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
   fixedout = true;
end
function inLocked = isInputSizeLockedImpl(~,idx)
   if idx == 1
     inLocked = false;
   else
```

```
            inLocked = true;
        end
    end
  end
end
```

Set Output Data Type

This example shows how to specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want bus output. To use bus output, you must define the bus data type in the base work space and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getOutputDataTypeImpl` method to specify the output data type as a double.

```
methods (Access = protected)
   function dataout = getOutputDataTypeImpl(~)
      dataout = 'double';
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function resetImpl(obj)
         obj.Count = 0;
      end
```

```
        function y = stepImpl(obj,u1,u2)
           % Add to count if u1 is above threshold
           % Reset if u2 is true
           if (u2)
              obj.Count = 0;
           elseif (u1 > obj.Threshold)
              obj.Count = obj.Count + 1;
           end
           y = obj.Count;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
           if strcmp(name,'Count')
              sz = [1 1];
              dt = 'double';
              cp = false;
           else
              error(['Error: Incorrect State Name: ', name.']);
           end
        end
        function dataout = getOutputDataTypeImpl(~)
           dataout = 'double';
        end
        function sizeout = getOutputSizeImpl(~)
           sizeout = [1 1];
        end
        function cplxout = isOutputComplexImpl(~)
           cplxout = false;
        end
        function fixedout = isOutputFixedSizeImpl(~)
           fixedout = true;
        end
    end
end
```

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
   OutputBusName = 'bus_name';
end

methods (Access = protected)
   function out = getOutputDataTypeImpl(obj)
```

```
      out = obj.OutputBusName;
   end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the `MATLAB System` block

```
classdef busGain < matlab.System & matlab.system.mixin.Propagates
% busGain Apply a gain of two to bus input.

   properties
      GainK = 2;
   end

   properties(Nontunable)
      OutputBusName = 'bus_name';
   end

   methods (Access=protected)
      function out = stepImpl(obj,in)
         out.a = obj.GainK * in.a;
         out.b = obj.GainK * in.b;
      end

      function out = getOutputSizeImpl(obj)
         out = propagatedInputSize(obj, 1);
      end

      function out = isOutputComplexImpl(obj)
         out = propagatedInputComplexity(obj, 1);
      end

      function out = getOutputDataTypeImpl(obj)
         out = obj.OutputBusName;
      end

      function out = isOutputFixedSizeImpl(obj)
         out = propagatedInputFixedSize(obj,1);
      end
   end
end
```

Specify Whether Output Is Fixed- or Variable-Size

This example shows how to specify that System object output is fixed- or variable-size.

This example shows how to specify that a System object output is fixed-size. Use the `isOutputFixedSizeImpl` method when Simulink cannot infer the output type from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)
   function fixedout = isOutputFixedSizeImpl(~)
      fixedout = true;
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function resetImpl(obj)
         obj.Count = 0;
      end

      function y = stepImpl(obj,u1,u2)
```

```
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
               obj.Count = 0;
            elseif (u1 > obj.Threshold)
               obj.Count = obj.Count + 1;
            end
            y = obj.Count;
         end

         function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            if strcmp(name,'Count')
               sz = [1 1];
               dt = 'double';
               cp = false;
            else
               error(['Error: Incorrect State Name: ', name.']);
            end
         end
         function dataout = getOutputDataTypeImpl(~)
            dataout = 'double';
         end

Specify Discrete State Output Specification

This example shows how to specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the `matlab.System` base class and from the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property, which is used in the counter reset example.

```
methods (Access = protected)
   function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
      sz = [1 1];
      dt = 'double';
      cp = false;
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function resetImpl(obj)
```

```
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (u1 > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            sz = [1 1];
            dt = 'double';
            cp = false;
        end
        function dataout = getOutputDataTypeImpl(~)
            dataout = 'double';
        end
        function sizeout = getOutputSizeImpl(~)
            sizeout = [1 1];
        end
        function cplxout = isOutputComplexImpl(~)
            cplxout = false;
        end
        function fixedout = isOutputFixedSizeImpl(~)
            fixedout = true;
        end
    end
end
```

Set Model Reference Discrete Sample Time Inheritance

This example shows how to disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
   function flag = ...
       allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
     flag = false;
   end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

   % MyCounter Count values

    properties
       Threshold = 1;
    end

    properties (DiscreteState)
       Count
    end

    methods (Static, Access = protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('MyCounter',...
           'Title','My Enhanced Counter',...
           'Text', 'This counter is an enhanced version.');
      end
    end

    methods (Access = protected)
       function flag = ...
            allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
          flag = false
       end
       function setupImpl(obj,u)
```

```
            obj.Count = 0;
        end
        function y = stepImpl(obj,u)
            if (u > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
        function resetImpl(obj)
            obj.Count = 0;
        end
    end
end
```

Use Update and Output for Nondirect Feedthrough

This example shows how to implement nondirect feedthrough for a System object using the `updateImpl`, `outputImpl` and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the object's outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. This enables you to use that object in a feedback loop and prevent algebraic loops.

Subclass from the Nondirect Mixin Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from both the `matlab.System` base class and the `Nondirect` mixin class.

```
classdef IntegerDelaySysObj < matlab.System & ...
  matlab.system.mixin.Nondirect
```

Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)
   function updateImpl(obj,u)
      obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
   end
end
```

Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)
   function [y] = outputImpl(obj,~)
      y = obj.PreviousInput(end);
   end
end
```

Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```
methods (Access = protected)
```

```
    function flag = isInputDirectFeedthroughImpl(~,~)
       flag = false;
    end
end
```

Complete Class Definition File with Update and Output

```
classdef intDelaySysObj < matlab.System &...
     matlab.system.mixin.Nondirect &...
     matlab.system.mixin.CustomIcon
   % intDelaySysObj Delay input by specified number of samples.

   properties
      InitialOutput = 0;
   end
   properties (Nontunable)
      NumDelays = 1;
   end
   properties (DiscreteState)
      PreviousInput;
   end

   methods (Access = protected)
      function validatePropertiesImpl(obj)
         if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
            error('Number of delays must be positive non-zero scalar value.');
         end
         if (numel(obj.InitialOutput)>1)
            error('Initial Output must be scalar value.');
         end
      end

      function setupImpl(obj)
         obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
      end

      function resetImpl(obj)
         obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
      end

      function [y] = outputImpl(obj,~)
         y = obj.PreviousInput(end);
      end
      function updateImpl(obj, u)
         obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
```

```
      end
      function flag = isInputDirectFeedthroughImpl(~,~)
         flag = false;
      end
   end
end
```

Enable For Each Subsystem Support

This example shows how to enable using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the `MATLAB System` block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
   function flag = supportsMultipleInstanceImpl(obj)
       flag = true;
   end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

    properties (DiscreteState)
       count;
    end

    properties (Nontunable)
       seed = 20;
    end

    properties (Nontunable,Logical)
       useSeed = false;
    end

   methods (Access = protected)
       function y = stepImpl(obj,u1)
         % Initial use after reset/setup
         % and use the seed
         if (obj.useSeed && ~obj.count)
             rng(obj.seed);
         end
         obj.count = obj.count + 1;
         [m,n] = size(u1);
         % Uses default rng seed
         y = rand(m,n) + u1;
```

```
        end

       function setupImpl(obj)
           obj.count = 0;
       end
       function resetImpl(obj)
           obj.count = 0;
       end

        function flag = supportsMultipleInstanceImpl(obj)
          flag = obj.useSeed;
        end
   end
end
```

Methods Timing

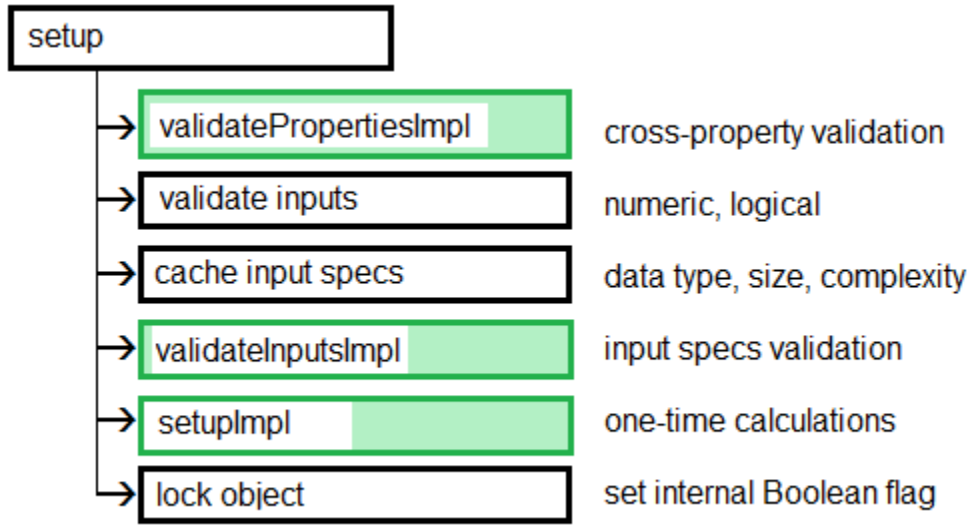
In this section...
“Setup Method Call Sequence” on page 41-94
“Step Method Call Sequence” on page 41-95
“Reset Method Call Sequence” on page 41-95
“Release Method Call Sequence” on page 41-96

The call sequence diagrams show the order in which actions are performed when you run the specified method. The background color or each action indicates the method type.

- White background — Sealed method
- Green background — User-implemented method
- White and green background — Sealed method that calls a user-implemented method

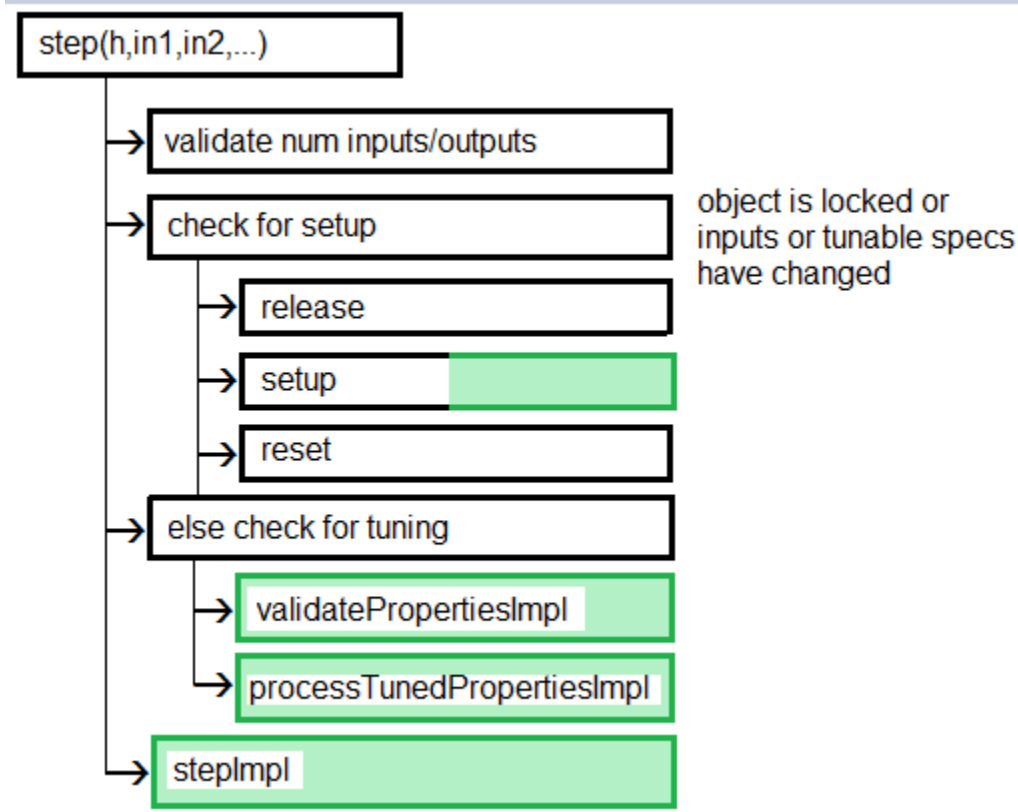
Setup Method Call Sequence

This hierarchy shows the actions performed when you call the `setup` method.



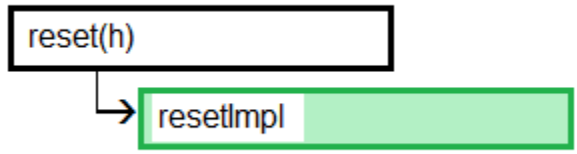
Step Method Call Sequence

This hierarchy shows the actions performed when you call the `step` method.



Reset Method Call Sequence

This hierarchy shows the actions performed when you call the `reset` method.



Release Method Call Sequence

This hierarchy shows the actions performed when you call the `release` method.

System Object Input Arguments and ~ in Code Examples

All methods, except static methods, expect the System object handle as the first input argument. You can use any name for your System object handle. In many examples, instead of passing in the object handle, ~ is used to indicate that the object handle is not used in the function. Using ~ instead of an object handle prevents warnings about unused variables.

What Are Mixin Classes?

Mixin classes are partial classes that you can combine in various combinations to form desired behaviors using multiple inheritance. System objects are composed of a base class, `matlab.System` and may include one or more mixin classes. You specify the base class and mixin classes on the first line of your class definition file.

The following mixin classes are available for use with System objects.

- `matlab.system.mixin.CustomIcon` — Defines a block icon for System objects in the `MATLAB System` block
- `matlab.system.mixin.FiniteSource` — Adds the `isDone` method to System objects that are sources
- `matlab.system.mixin.Nondirect` — Allows the System object, when used in the `MATLAB System` block, to support nondirect feedthrough by making the runtime callback functions, `output` and `update` available
- `matlab.system.mixin.Propagates` — Enables System objects to operate in the `MATLAB System` block using the interpreted execution

Best Practices for Defining System Objects

A System object is a specialized kind of MATLAB object that is optimized for iterative processing. Use System objects when you need to call the `step` method multiple times or process data in a loop. When defining your own System object, use the following suggestions to help your code run efficiently.

- Define all one-time calculations in the `setupImpl` method and cache the results in a private property. Use the `stepImpl` method for repeated calculations.
- If properties are accessed more than once in the `stepImpl` method, cache those properties as local variables inside the method. A typical example of multiple property access is a loop. Iterative calculations using cached local variables run faster than calculations that must access the properties of an object. When the calculations for the method complete, you can save the local cached results back to the properties of that System object. Copy frequently used tunable properties into private properties. This best practice also applies to the `updateImpl` and `outputImpl` methods.

  In this example, `k` is accessed multiple times in each loop iteration, but is saved to the object property only once.

  ```
  function y = stepImpl(obj,x)
    k = obj.MyProp;
    for p=1:100
      y = k * x;
      k = k + 0.1;
    end
    obj.MyProp = k;
  end
  ```

- Property default values are shared across all instances of an object. Two instances of a class can access the same default value if that property has not been overwritten by either instance.
- Do not use string comparisons or string-based switch statements in the `stepImpl` method. Instead, create a method handle in `setupImpl`. This handle points to a method in the same class definition file. Use that handle in a loop in `stepImpl`.

  This example shows how to use method handles and cached local variables in a loop to implement an efficient object. In `setupImpl`, choose `myMethod1` or `myMethod2` based on a string comparison and assign the method handle to the `pMethodHandle` property. Because there is a loop in `stepImpl`, assign the `pMethodHandle` property to a local method handle, `myFun`, and then use `myFun` inside the loop.

```
classdef MyClass < matlab.System
  function setupImpl(obj)
    if strcmp(obj.Method, 'Method1')
      obj.pMethodHandle = @myMethod1;
    else
      obj.pMethodHandle = @myMethod2;
    end
  end
  function y = stepImpl(obj,x)
    myFun = obj.pMethodHandle;
      for p=1:1000
        y = myFun(obj,x)
      end
    end
  end
  function y = myMethod1(x)
    y = x+1;
  end
  function y = myMethod2(x)
    y = x-1;
  end
end
```

- If the number of System object inputs does not change, do not implement the `getNumInputsImpl` method. Also do not implement the `getNumInputsImpl` method when you explicitly list the inputs in the `stepImpl` method instead of using `varargin`. The same caveats apply to the `getNumOutputsImpl` and `varargout` outputs.
- For the `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- If the variables in a method do not need to retain their values between calls use local scope for those variables in that method.
- For properties that do not change, define them in as `Nontunable` properties. `Tunable` properties have slower access times than `Nontunable` properties
- Use the `protected` or `private` attribute instead of the `public` attribute for a property, whenever possible. Some `public` properties have slower access times than `protected` and `private` properties.
- Avoid using customized `step`, `get`, or `set` methods, whenever possible.

- Avoid using string comparisons within customized `step`, `get`, or `set` methods, whenever possible. Use `setupImpl` for string comparisons instead.
- Specify Boolean values using `true` or `false` instead of `1` or `0`, respectively.

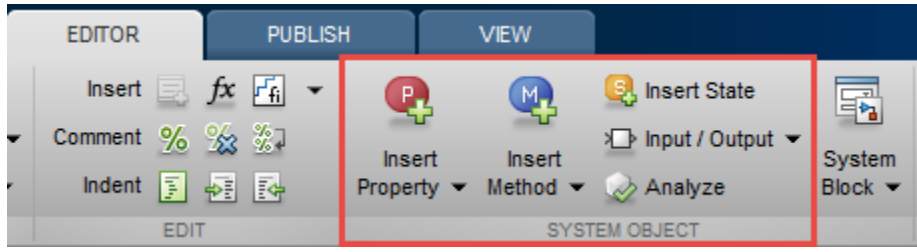
Insert System Object Code Using MATLAB Editor

In this section...
“Define System Objects with Code Insertion” on page 41-102
“Create Fahrenheit Temperature String Set” on page 41-105
“Create Custom Property for Freezing Point” on page 41-106
“Define Input Size As Locked” on page 41-107

Define System Objects with Code Insertion

You can define System objects from the MATLAB Editor using code insertion options. When you select these options, the MATLAB Editor adds predefined properties, methods, states, inputs, or outputs to your System object. Use these tools to create and modify System objects faster, and to increase accuracy by reducing typing errors.

To access the System object editing options, create a new System object, or open an existing one.



To add predefined code to your System object, select the code from the appropriate menu. For example, when you click **Insert Property** > **Numeric**, the MATLAB Editor adds the following code:

```
properties(Nontunable)
    Property
end
```

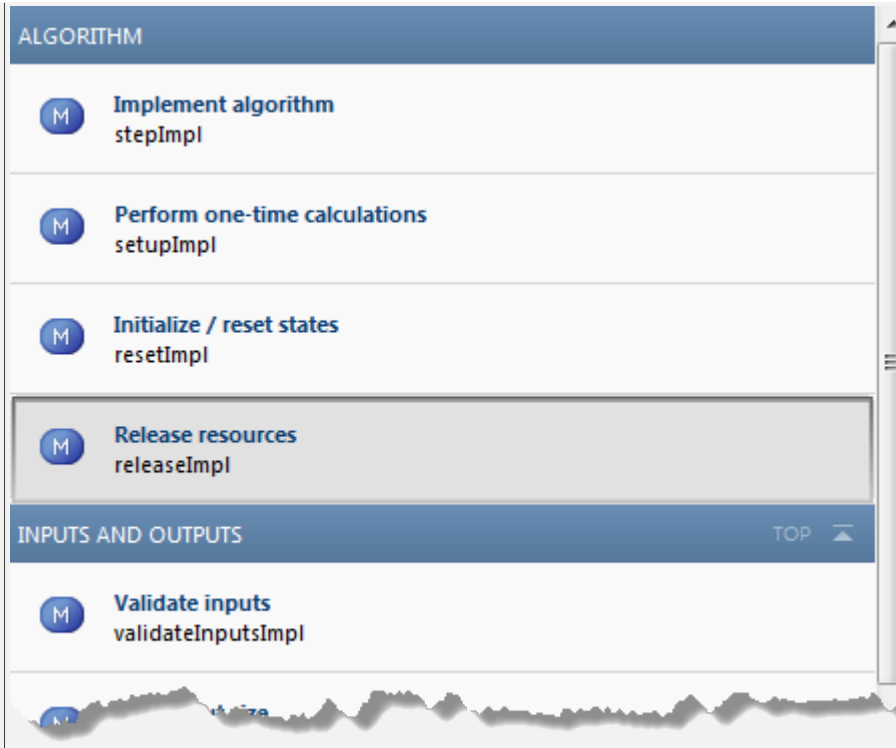
The MATLAB Editor inserts the new property with the default name `Property`, which you can rename. If you have an existing properties group with the `Nontunable`

attribute, the MATLAB Editor inserts the new property into that group. If you do not have a property group, the MATLAB Editor creates one with the correct attribute.

Insert Options

Properties	Properties of the System object: Numeric, Logical, String Set, Positive Integer, Tunable Numeric, Private, Protected, and Custom. When you select String Set or Custom Properties, a separate dialog box opens to guide you in creating these properties.

Methods	Methods commonly used in System object definitions. The MATLAB Editor creates only the method structure. You specify the actions of that method.
	
	The **Insert Method** menu organizes methods by categories, such as **Algorithm**, **Inputs and Outputs**, and **Properties and States**. When you select a method from the menu, the MATLAB Editor inserts the method template in your System object code. In this example, selecting **Insert Method > Release resources** inserts the following code:
	
	`function releaseImpl(obj)`
	`    % Release resources, such as file handles`
	`end`
	
	If an method from the **Insert Method** menu is present in the System object code, that method is shown shaded on the **Insert Method** menu:



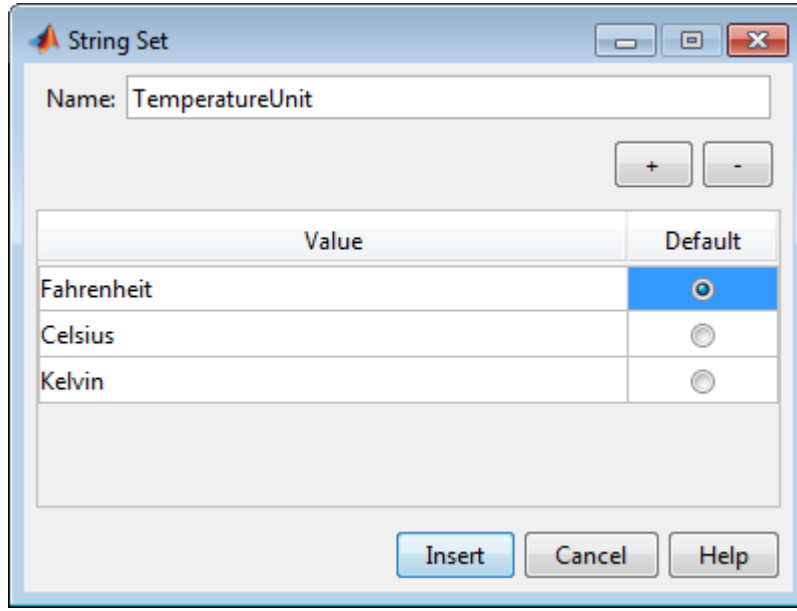
States	Properties containing the `DiscreteState` attribute.

Inputs / Outputs	Inputs, outputs, and related methods, such as **Validate inputs** and **Lock input size**.
	
	When you select an input or output, the MATLAB Editor inserts the specified code in the `stepImpl` method. In this example, selecting **Insert** > **Input** causes the MATLAB Editor to insert the required input variable `u2`. The MATLAB Editor determines the variable name, but you can change it after it is inserted.
	
	`function y = stepImpl(obj,u,u2)`
	`  % Implement algorithm. Calculate y as a function of input u and`
	`  % discrete states.`
	`  y = u;`
	`end`

Create Fahrenheit Temperature String Set

1. Open a new or existing System object.
2. In the MATLAB Editor, select **Insert Property** > **String Set**.
3. In the **String Set** dialog box, under **Name**, replace `Color` with `TemperatureUnit`.
4. Remove the existing `Color` property values with the - (minus) button.
5. Add a property value with the + (plus) button. Enter `Fahrenheit`.
6. Add another property value with +. Enter `Celsius`.
7. Add another property value with +. Enter `Kelvin`.
8. Select `Fahrenheit` as the default value by clicking **Default**.

   The dialog box now looks as shown:



9. To create this string set and associated properties, with the default value selected, click **Insert**.

Examine the System object definition. The MATLAB Editor has added the following code:

```
properties (Nontunable)
```

```
    TemperatureUnit = 'Fahrenheit';
  end

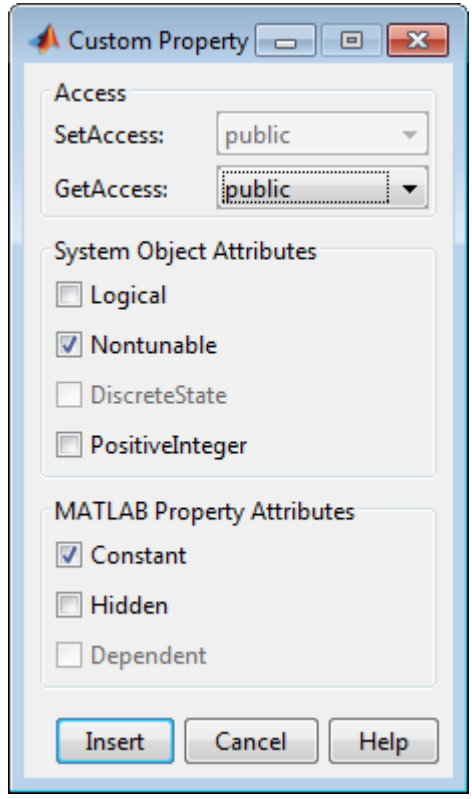
  properties(Constant, Hidden)
    TemperatureUnitSet = matlab.system.StringSet({'Fahrenheit','Celsius','Kelvin'});
  end
```

For more information on the `StringSet` class, see matlab.System.StringSet.

Create Custom Property for Freezing Point

1. Open a new or existing System object.
2. In the MATLAB Editor, select **Insert Property > Custom Property**.
3. In the Custom Property dialog box, under **System Object Attributes**, select **Nontunable**. Under **MATLAB Property Attributes**, select **Constant**. Leave **GetAccess** as `public`. **SetAccess** is grayed out because properties of type constant can not be set using System object methods.

   The dialog box now looks as shown:



4 To insert the property into the System object code, click **Insert**.

```
properties(Nontunable, Constant)
    Property
end
```

5 Replace `Property` with your property.

```
properties(Nontunable, Constant)
    FreezingPointFahrenheit = 32;
end
```

Define Input Size As Locked

1 Open a new or existing System object.

2 In the MATLAB Editor, select **Insert Method** > **Lock input size**.

The MATLAB Editor inserts this code into the System object:

```
function flag = isInputSizeLockedImpl(obj,index)
    % Return true if input size is not allowed to change while
    % system is running
    flag = true;
end
```

Analyze System Object Code

In this section...
“View and Navigate System object Code” on page 41-109
“Example: Go to StepImpl Method Using Analyzer” on page 41-109

View and Navigate System object Code

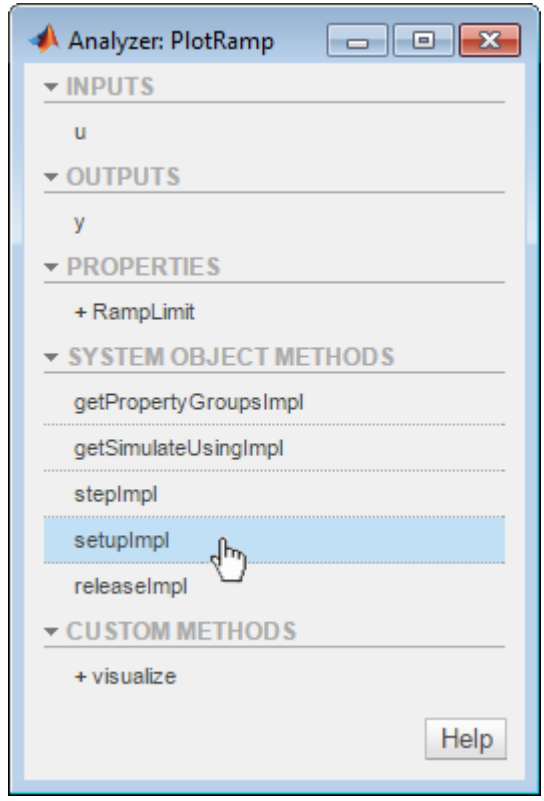
View and navigate System object code using the Analyzer.

The Analyzer displays all elements in your System object code.

- Navigate to a specific input, output, property, state, or method by clicking the name of that element.
- Expand or collapse element sections with the arrow buttons.
- Identify access levels for properties and custom methods with the + (public), # (protected), and – (private) symbols.

Example: Go to StepImpl Method Using Analyzer

1. Open an existing System object.
2. Select **Analyze**.
3. Click stepImpl.



The cursor in the MATLAB Editor window jumps to the `stepImpl` method.

- “Insert System Object Code Using MATLAB Editor” on page 41-102

Define System Object for Use in Simulink

In this section...
“Develop System Object for Use in System Block” on page 41-112
“Define Block Dialog Box for Plot Ramp” on page 41-113

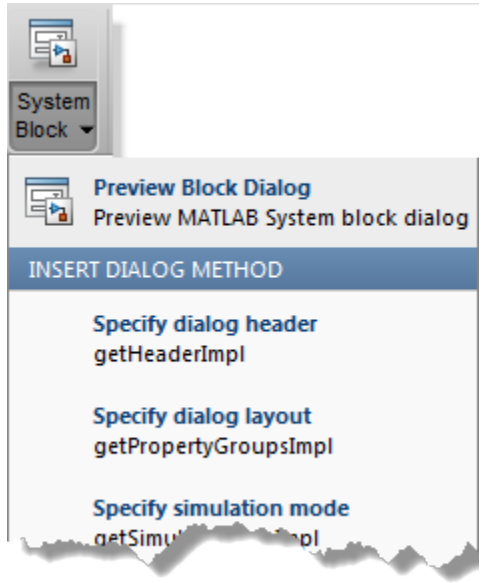
Develop System Object for Use in System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog design as you define the System object.
- Add dialog customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the Preview Dialog Box.

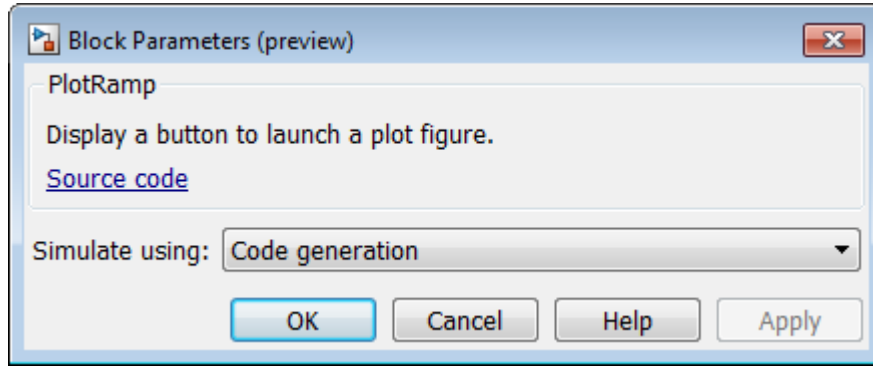


Define Block Dialog Box for Plot Ramp

1. Create a System object and name it `PlotRamp`. This name becomes the block dialog box title. Save the System object.
2. Add a comment that contains the block description.

   ```
   % Display a button to launch a plot figure.
   ```

   This comment becomes the block parameters dialog box description, under the block title.
3. Select **System Block > Preview Block Dialog**. The block dialog box displays as you develop the System object.



4 Add a ramp limit by selecting **Insert Property** > **Numeric**. Then change the property name and set the value to `10`.

```
properties (Nontunable)
  RampLimit = 10;
end
```

5 Using the **System Block** menu, insert the `getPropertyGrouplsImpl` method.

```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
    end
end
```

6 Add code to create the group for the visualize action..

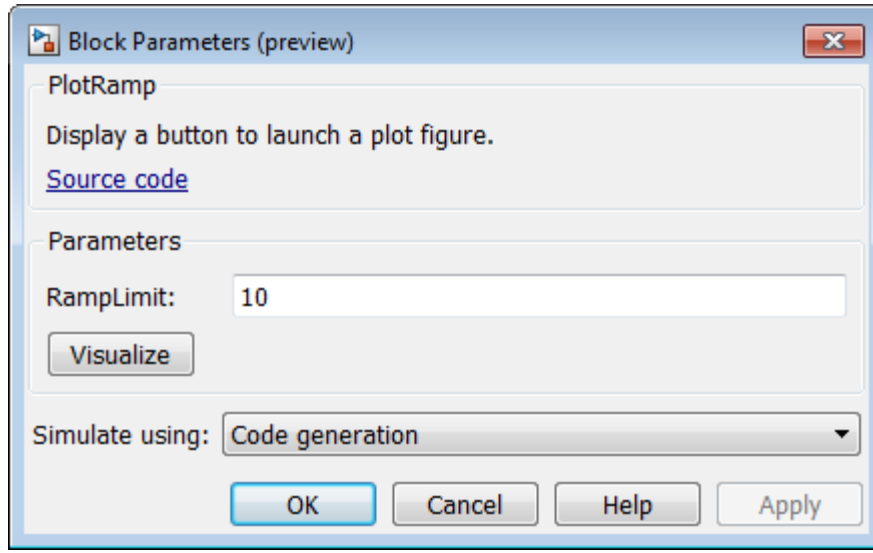
```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(~,obj)...
          visualize(obj),'Label','Visualize');
    end
end
```

7 Add a function that adds code to display the **Visualize** button on the dialog box.

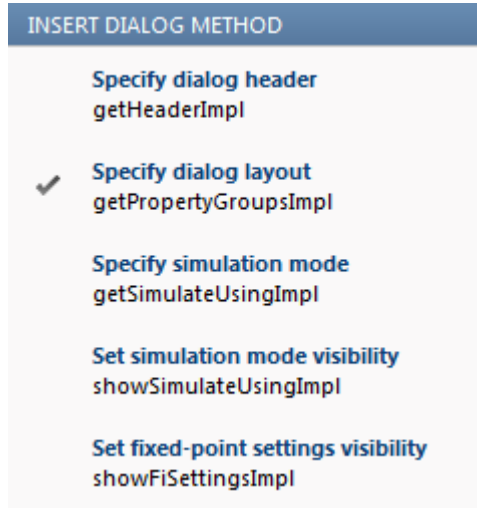
```
methods
  function visualize(obj)
    figure;
```

```
        d = 1:obj.RampLimit;
        plot(d);
    end
end
```

8 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.



The **System Block** menu also displays checks next to the methods you have implemented, which can help you track your development.



The class definition file now has all the code necessary for the PlotRamp System object.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

  methods(Static, Access=protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(~,obj)...
            visualize(obj),'Label','Visualize');
    end
  end

  methods
    function visualize(obj)
      figure;
      d = 1:obj.RampLimit;
      plot(d);
    end
  end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

MATLAB System Block

In this section...
"Why Use the MATLAB System Block?" on page 42-2
"Choosing the Right Block Type" on page 42-2
"System Objects" on page 42-3
"Interpreted Execution or Code Generation" on page 42-3
"MATLAB System Block Limitations" on page 42-4
"MATLAB System and System Objects Examples" on page 42-5

Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The `MATLAB System` block enables you to use System objects in Simulink.

The `MATLAB System` block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block

- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block
- Fcn block

For help on choosing the right block, see “Types of Custom Blocks” on page 37-2 and “Comparison of Custom Block Functionality” on page 37-6.

System Objects

Before you use a `MATLAB System` block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Define System Objects”.

Note: To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

System objects exist in other MATLAB products. `MATLAB System` block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a `MATLAB System` block for it.

Interpreted Execution or Code Generation

You can use `MATLAB System` blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 44-2.

`MATLAB System` Block Limitations

These capabilities are currently not supported.

Category	Limitation Description	Workaround
System Objects	Tunable logical and string properties of the System object are nontunable parameters in the `MATLAB System` block.	—
Data Types	• The `MATLAB System` block does not support virtual buses as input or output. • The `MATLAB System` block does not support nonvirtual buses that contain variable-size signals. • System objects cannot use the enumerated data type. • System objects cannot use fixed-point signals with nonbinary point scaling or nonzero bias. • System objects cannot use user-defined opaque data types.	—
Sample Time	Cannot use `MATLAB System` blocks to model continuous time or multirate systems.	—
Linearizations	Cannot use Jacobian based linearization.	—

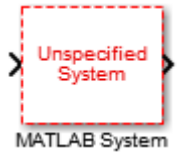
Implement a MATLAB System Block

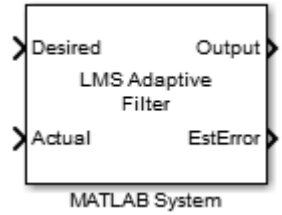
Implement a block and assign a System object to it. You can then explore the block to see the effect.

1. Create a new model and add the MATLAB System block from the User-Defined Functions library.



2. In the block dialog box, from the **New** list, select Basic, Advanced, or Simulink Extension if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
3. Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

   The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named lmsSysObj in your current folder. The block updates as shown in the figure:



Note: After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

Understanding the `MATLAB System` Block

1. Double-click the block. The `MATLAB System` dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

   The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

   - Converted the System object to P-code
   - Overridden the default behavior using the `getHeaderImpl` method

2. Click **Source code** and observe that the public and active properties in the System object appear in the `MATLAB System` block dialog box as block parameters.
3. Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each `MATLAB System` block if there is only one tab, or the bottom of the first of multiple tabs.)

You might want to add that note about not being able to get to the MATLAB System block dialog box the same way after you've associated the block with a System object. Look under mask is one way you can get to it.

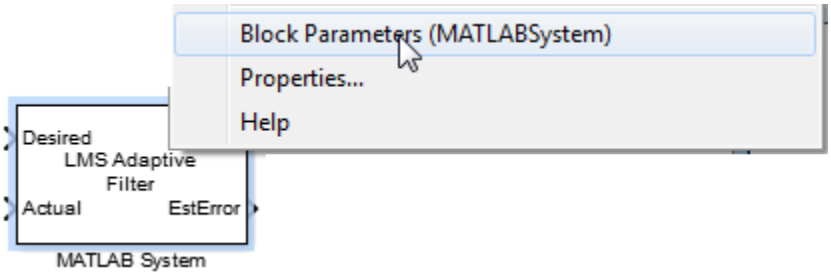
Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the `MATLAB System` block and select Block Parameters (MATLABSystem). Then, use the block dialog box to identify a new class name in **System object name**. For more information, see "Implement a MATLAB System Block" on page 42-7.



Related Examples

- "System Identification for an FIR System Using MATLAB System Blocks"

Change Block Icon and Port Labels

To change the icon appearance of your block, you must use the `matlab.system.mixin.CustomIcon` class. You can define port labels using System object methods.

1. Add the `matlab.system.mixin.CustomIcon` class name to the System object, after the `matlab.System` class. For example:

   ```
   classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
   ```

   This code subclasses from the `matlab.system.mixin.CustomIcon` class in addition to the `matlab.System` base class.

2. To define the icon, implement the `getIconImpl` method.

3. To define the port labels, implement the following optional methods to change the input and output port labels. You do not need the `matlab.system.mixin.CustomIcon` class to use these methods.

   ```
   getInputNamesImpl
   getOutputNamesImpl
   ```

If you do not implement these methods, the System object uses the input and output port names from the `stepImpl` method. If you are using the `matlab.system.mixin.Nondirect` class and do not implement these methods, the System object uses the input names from `updateImpl` and the output port names from `OutputImpl`.

Modify `MATLAB System` Block Dialog

To change the `MATLAB System` block dialog, implement the methods for the following classes:

Description	matlab.system.display Methods
Define header text for property group.	`matlab.system.display.Header`
Group properties together.	`matlab.system.display.Section`
Group properties into a separate tab.	`matlab.system.display.SectionGroup`

Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the getOutputDataTypeImpl method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

Note: If the output is the same bus type as the input, do not use the propagatedInputDataType method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `matlab.system.mixin.Nondirect` class. This class uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

A delay object is an example of a nondirect feedthrough object.

1. Add the `matlab.system.mixin.Nondirect` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

   ```
   IntegerDelaySysObj < matlab.System & matlab.system.mixin.Nondirect
   ```

   This step subclasses from the `matlab.system.mixin.Nondirect` class in addition to the `matlab.System` base class.

2. Implement the following methods:

   ```
   outputImpl
   updateImpl
   ```

   When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

3. If the System object supports code generation and does not inherit from `matlab.system.mixin.Propagates`, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method if you want nondefault behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

Simulation Modes

Interpreted Execution vs. Code Generation

You can use `MATLAB System` block in Simulink models for simulation via interpreted execution or code generation. Implementing a `MATLAB System` block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of each `MATLAB System` block if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

  Note: With interpreted execution, if you set the **Optimization > Use division for fixed-point net slope computation** parameter to `'On'` or `'Use division for reciprocals of integers only'` in the Configuration Parameters dialog box, you might get unoptimized numeric results. This is because MATLAB code does not support this parameter.

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

Action	Select	Pros	Cons
Upon first model run, simulate and generate code for `MATLAB System` using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code.	`Code generation` (default)	Potentially better performance.	System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly.

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 42-30.

Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same block, where blocks are considered the same if they

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and do not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

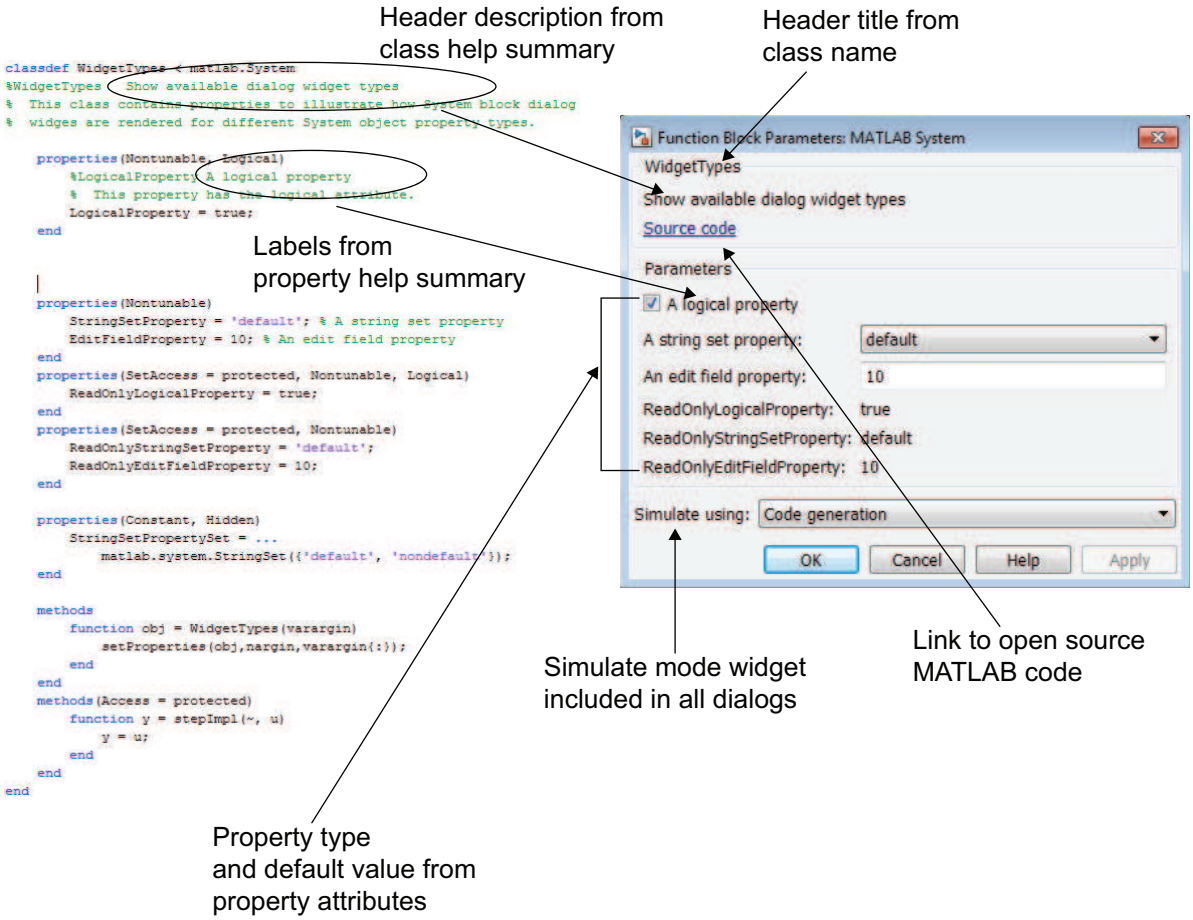
Mapping System Objects to Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section describes System object to block dialog box mapping using the System Identification for an FIR System Using MATLAB System Blocks example. This example uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

In this section...
"System Object to Block Dialog Box Default Mapping" on page 42-19
"System Object to Block Dialog Box Custom Mapping" on page 42-21

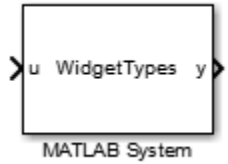
System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements if you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all `MATLAB System` block dialog boxes.)



The `Delay` block from the System Identification for an FIR System Using MATLAB System Blocks is an example of a block that uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 42-14.

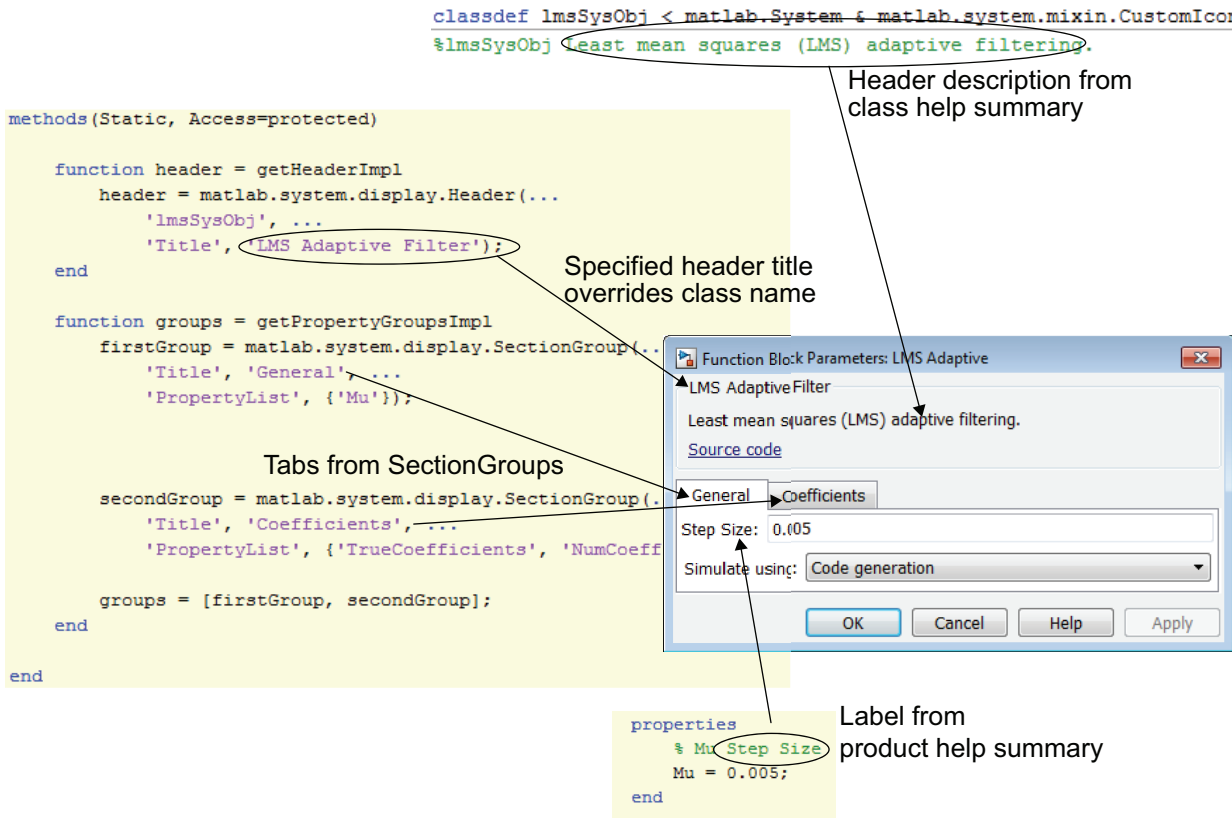


For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 42-21.

System Object to Block Dialog Box Custom Mapping

The `LMS Adaptive` block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` method from `matlab.system.display.Header` and `getPropertyGroupsImpl` method from `matlab.system.display.SectionGroup` to customize these block dialog elements.

The `LMS Adaptive Filter` block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the lmsSysObj System object.



The source code for this System object also defines two input and output ports for the block.

```
function num = getNumInputsImpl(~)
    num = 2;
end

function num = getNumOutputsImpl(~)
    num = 2;
end

function icon = getIconImpl(~)
    icon = sprintf('LMS Adaptive\nFilter');
end

  function [name1, name2] = getInputNamesImpl(~)
      name1 = 'Desired';
      name2 = 'Actual';
  end

  function [name1, name2] = getOutputNamesImpl(~)
      name1 = 'Output';
      name2 = 'EstError';
  end
```

Considerations for Using System Objects in Simulink

In this section...

"System Objects in Simulink" on page 42-24
"System Objects in For Each Subsystems" on page 42-25

System Objects in Simulink

There are differences in how you can use System objects in a `MATLAB System` block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

Variable-Size Signals

To use variable-size signals in a System object, you must implement `matlab.system.mixin.Propagates` methods. In particular, use the isOutputFixedSizeImpl method to specify if an output is variable-size or fixed-size. This is true for interpreted execution and code generation simulation methods.

Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding `MATLAB System` block. If a System object property is tunable, it is also tunable in the `MATLAB System` block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the `MATLAB System` block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

System Objects as Properties

The `MATLAB System` block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the `MATLAB System` block dialog box.

Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

System Objects in For Each Subsystems

To use the MATLAB System block within a `For Each Subsystem` block, implement the `matlab.system` supportsMultipleInstanceImpl method. This method should return `true`. The MATLAB System block clones the System object for each `For Each Subsystem` iteration.

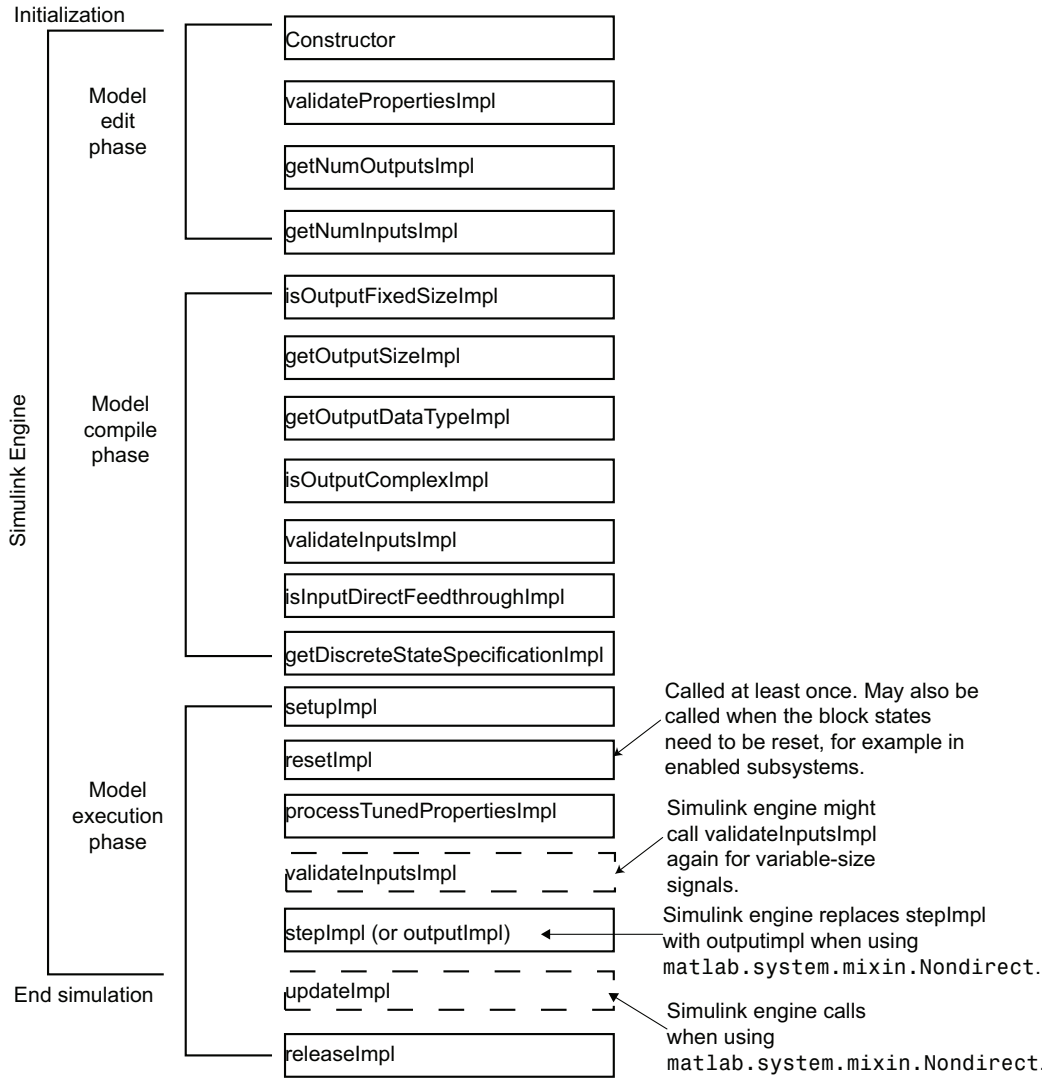
Simulink Engine Interaction with System Object Methods

Simulink Engine Phases Mapped to System Object Methods

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.



Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.

- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, `getOutputSizeImpl` when using `matlab.system.mixin.Propagates`.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring SimState, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

Add and Implement Propagation Methods

In this section...
"When to Use Propagation Methods" on page 42-30
"Add Propagation Methods to System Objects" on page 42-30
"Implement Propagation Methods" on page 42-31

When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case. Use these methods to specify information for the outputs.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of `MATLAB System` blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

Add Propagation Methods to System Objects

Propagation methods are in the class `matlab.system.mixin.Propagates`. To add these methods to the System object, add the `matlab.system.mixin.Propagates` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
classdef Counter < matlab.System & matlab.system.mixin.Propagates
```

Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the `MATLAB System` block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets dimensions of output ports. The associated method is `getOutputSize`	`getOutputSizeImpl`	• Only one input • Only one output • An input size that is the same as the output size	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Gets data types of output ports. The associated method is `getOutputDataType`.	`getOutputDataTypeImpl`	• Only one input • Only one output • Output data type always the same as the input data type	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Indicates whether output ports are complex or not. The associated method is `isOutput-Complex`.	`isOutputComplexImpl`	• Only one input • Only one output • Output complexity always the same as th input complexity	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals

Description	Propagation Method	Default Implementation Should Suffice if	Example
			• Analysis block in Illustration of Law of Large Numbers
Whether output ports are fixed size. The associated method is `isOutputFixedSize`.	`isOutputFixedSizeImpl`	• Only one input • Only one output • Output and input are fixed-size	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Gets the size, data type, and complexity of a discrete state property. The associated method is `getDiscreteStateSpecification`	`getDiscreteStateSpecificationImpl`	No `DiscreteState` properties	N/A

Troubleshoot System Objects in Simulink

In this section...
“Class Not Found” on page 42-33
“Error Invoking Object Method” on page 42-33
“Performance” on page 42-34

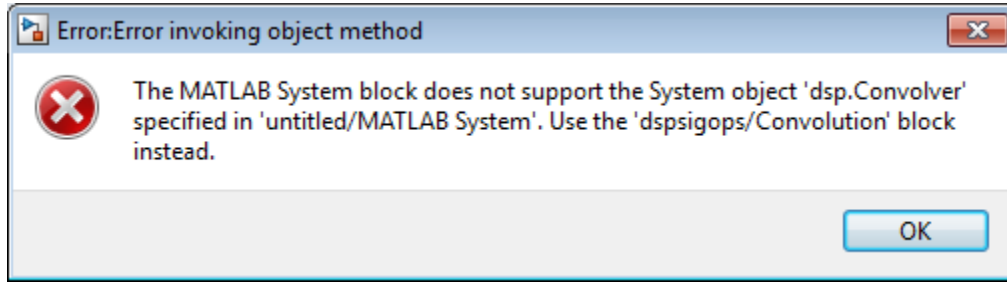
Class Not Found

The `MATLAB System` block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

Error Invoking Object Method

The `MATLAB System` block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:



This message indicates that there is an existing dedicated and optimized block that you should use.

Performance

For fastest performance, set the block **Simulate using** parameter to `Code generation`. This setting allows the `MATLAB System` block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to `Interpreted execution`. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use propagation methods to specify the block input and output port information. The `MATLAB System` block then propagates this signal attribution information.

When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

To:	Use:
Deploy an application that uses handle graphics	MATLAB Compiler
Use Java	MATLAB Compiler SDK™
Use toolbox functions that do not support code generation	Toolbox functions that you rewrite for desktop and embedded applications
Deploy MATLAB based GUI applications on a supported MATLAB host	MATLAB Compiler
Deploy web-based or Windows applications	MATLAB Compiler SDK

To:	Use:
Interface C code with MATLAB	MATLAB `mex` function

Prerequisites for C/C++ Code Generation from MATLAB

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

  C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

  Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

  You can choose whether the generated code uses static or dynamic memory allocation.

  With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

  Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

  Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

  To improve the speed of the generated code:

  - Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
  - Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

Why Are There Differences?

To convert MATLAB code to C/C++ code that works efficiently, the code generation process introduces optimizations that intentionally cause the generated code to behave differently — and sometimes produce different results — from the original source code. This section describes these differences.

Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See "Code Generation for Characters and Strings" on page 47-8.

Order of Evaluation in Expressions

Generated code does not enforce order of evaluation in expressions. For most expressions, order of evaluation is not significant. However, for expressions with side effects, the

generated code may produce the side effects in different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

  ```
  A = f1() + f2();
  ```

  as

  ```
  A = f1();
  A = A + f2();
  ```

  so that the generated code calls `f1` before `f2`.
- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

  ```
  [y, y.f, y.g] = foo;
  ```

  as

  ```
  [y, a, b] = foo;
  y.f = a;
  y.g = b;
  ```
- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

  ```
  [y, y.f, y.g] = z{:};
  ```

  as

  ```
  [y, a, b] = z{:};
  y.f = a;
  ```

```
y.g = b;
```

Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See "Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays" on page 48-23.

Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See "Incompatibility with MATLAB in Determining Size of Empty Arrays" on page 48-24.

Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code

Delete all elements of an m-by-n array by using the `colon` operator (`:`).	`coder.varsize('X',[4,4],[1,1]);`
	`X = zeros(2);`
	`X(:) = [];`
		`0-by-0`	`1-by-0`

Delete all elements of a row vector by	`coder.varsize('X',[1,4],[0,1]);`
	`X = zeros(1,4);`
	`X(:) = [];`
		`0-by-0`	`1-by-0`

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code
using the `colon` operator (`:`).			

Delete all elements of a column vector by using the `colon` operator (`:`).	`coder.varsize('X',[4,1],[1,0]);`
	`X = zeros(4,1);`
	`X(:) = [];`
		`0-by-0`	`0-by-1`

Delete all elements of a column vector by deleting one element at a time.	`coder.varsize('X',[4,1],[1,0]);`
	`X = zeros(4,1);`
	`for i = 1:4`
	`  X(1)= [];`
	`end`
		`1-by-0`	`0-by-1`

Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in the following situations:

When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

NaN and Infinity Patterns

The generated code might not produce exactly the same pattern of `NaN` and `inf` values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a `NaN`, output from the generated code should also contain a `NaN`, but not necessarily in the same place.

Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

MATLAB Class Initial Values

Before code generation, at class loading time, MATLAB computes class initial values. The code generation software uses the value that MATLAB computes. It does not recompute the initial value. If the initialization uses a function call to compute the initial value, the code generation software does not execute this function. If the function modifies a global state, for example, a persistent variable, code generation software might provide a different initial value than MATLAB. For more information, see "Defining Class Properties for Code Generation" on page 52-4.

Variable-Size Support for Code Generation

See "Incompatibilities with MATLAB in Variable-Size Support for Code Generation" on page 48-21.

Complex Numbers

See "Code Generation for Complex Data" on page 47-4.

MATLAB Language Features Supported for C/C++ Code Generation

MATLAB Features That Code Generation Supports

Code generation from MATLAB supports the following language features:

- N-dimensional arrays (see "Array Size Restrictions for Code Generation" on page 47-9)
- Matrix operations, including deletion of rows and columns
- Variable-sized data (see "Variable-Size Data Definition for Code Generation" on page 48-3)
- Subscripting (see "Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation" on page 48-27)
- Complex numbers (see "Code Generation for Complex Data" on page 47-4)
- Numeric classes (see "Supported Variable Types" on page 46-17)
- Double-precision, single-precision, and integer math
- Fixed-point arithmetic
- Program control statements `if`, `switch`, `for`, `while`, and `break`
- Arithmetic, relational, and logical operators
- Local functions
- Persistent variables (see "Define and Initialize Persistent Variables" on page 46-10)
- Global variables.
- Structures (see "Structure Definition for Code Generation" on page 49-2)
- Cell Arrays (see "Cell Arrays")
- Characters (see "Code Generation for Characters and Strings" on page 47-8)
- Function handles (see "Function Handle Definition for Code Generation" on page 53-2)
- Frames
- Variable length input and output argument lists
- Subset of MATLAB toolbox functions (see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2)

- Subset of functions and System objects in Aerospace Toolbox, Communications System Toolbox, Computer Vision System Toolbox, DSP System Toolbox, Fixed-Point Designer, Image Processing Toolbox™, Signal Processing Toolbox™, Phased Array System Toolbox™, Statistics and Machine Learning Toolbox™ (see "Functions and Objects Supported for C and C++ Code Generation — Category List" on page 44-164)
- MATLAB classes (see "MATLAB Classes Definition for Code Generation" on page 52-2)
- Function calls (see "Resolution of Function Calls for Code Generation" on page 55-2)

MATLAB Language Features That Code Generation Does Not Support

Code generation from MATLAB does not support the following frequently used MATLAB constructs:

- Anonymous functions
- Categorical Arrays
- Date and Time Arrays
- Java
- Map Containers
- Nested functions
- Recursion
- Sparse matrices
- Tables
- Time Series objects
- `try`/`catch` statements

This list is not exhaustive. To see if a construct is supported for code generation, see "MATLAB Features That Code Generation Supports" on page 43-13.

Functions, Classes, and System Objects Supported for Code Generation

- "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2
- "Functions and Objects Supported for C and C++ Code Generation — Category List" on page 44-164

Functions and Objects Supported for C and C++ Code Generation — Alphabetical List

You can generate efficient C and C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These function, classes, and System objects appear in alphabetical order in the following table.

To find supported functions, classes, and System objects by MATLAB category or toolbox, see "Functions and Objects Supported for C and C++ Code Generation — Category List" on page 44-164.

Note: For more information on code generation for fixed-point algorithms, refer to "Code Acceleration and Code Generation from MATLAB".

Name	Product	Remarks and Limitations
`abs`	MATLAB	—
`abs`	Fixed-Point Designer	—
`accumneg`	Fixed-Point Designer	—
`accumpos`	Fixed-Point Designer	—
`acos`	MATLAB	When the input value `x` is real, but the output should be complex, generates an error during simulation and returns `NaN` in generated code. To get the complex result, make the input value complex by passing in `complex(x)`.
`acosd`	MATLAB	—
`acosh`	MATLAB	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.

Name	Product	Remarks and Limitations
`acot`	MATLAB	—
`acotd`	MATLAB	—
`acoth`	MATLAB	—
`acsc`	MATLAB	—
`acscd`	MATLAB	—
`acsch`	MATLAB	—
`adaptthresh`	Image Processing Toolbox	The `ForegroundPolarity` and `Statistic` arguments must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The `NeighborhoodSize` argument must be a compile-time constant.
`add`	Fixed-Point Designer	Code generation in MATLAB does not support the syntax `F.add(a,b)`. You must use the syntax `add(F,a,b)`.
affine2d	Image Processing Toolbox	When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`aictest`	Phased Array System Toolbox	Does not support variable-size inputs.
`airy`	MATLAB	Always returns a complex result.
`albersheim`	Phased Array System Toolbox	Does not support variable-size inputs.
`all`	MATLAB	“Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30

Name	Product	Remarks and Limitations
`all`	Fixed-Point Designer	—
`ambgfun`	Phased Array System Toolbox	Does not support variable-size inputs.
`and`	MATLAB	—
`angdiff`	Robotics System Toolbox™	Supports `MATLAB Function` block: Yes
`any`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`any`	Fixed-Point Designer	—
`aperture2gain`	Phased Array System Toolbox	Does not support variable-size inputs.
`asec`	MATLAB	—
`asecd`	MATLAB	—
`asech`	MATLAB	—
`asin`	MATLAB	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`asind`	MATLAB	—
`asinh`	MATLAB	—
`assert`	MATLAB	• Generates specified error messages at compile time only if all input arguments are constants or depend on constants. Otherwise, generates specified error messages at run time. • For standalone code generation, excluded from the generated code.

Name	Product	Remarks and Limitations
`assignDetections-ToTracks`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
`atan`	MATLAB	—
`atan2`	MATLAB	—
`atan2`	Fixed-Point Designer	—
`atan2d`	MATLAB	—
`atand`	MATLAB	—
`atanh`	MATLAB	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
audioDeviceReader	Audio System Toolbox™	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
audioDeviceWriter	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
audioDeviceWriter	DSP System Toolbox	"System Objects in MATLAB Code Generation"
audioOscillator	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`audioPluginInterface`	Audio System Toolbox	Supports MATLAB Function Block: Yes
`audioPluginParameter`	Audio System Toolbox	Supports MATLAB Function Block: Yes
audioPlugin	Audio System Toolbox	Supports MATLAB Function Block: Yes
audioPluginSource	Audio System Toolbox	Supports MATLAB Function Block: Yes

Name	Product	Remarks and Limitations
`axang2quat`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`axang2rotm`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`axang2tform`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`az2broadside`	Phased Array System Toolbox	Does not support variable-size inputs.
`azel2phitheta`	Phased Array System Toolbox	Does not support variable-size inputs.
`azel2phithetapat`	Phased Array System Toolbox	Does not support variable-size inputs.
`azel2uv`	Phased Array System Toolbox	Does not support variable-size inputs.
`azel2uvpat`	Phased Array System Toolbox	Does not support variable-size inputs.
`azelaxes`	Phased Array System Toolbox	Does not support variable-size inputs.
`bandwidth`	MATLAB	—
`barthannwin`	Signal Processing Toolbox	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`bartlett`	Signal Processing Toolbox	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`bboxOverlapRatio`	Computer Vision System Toolbox	Supports`MATLAB Function` block: No
`bbox2points`	Computer Vision System Toolbox	Supports `MATLAB Function` block: Yes
`beat2range`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`besselap`	Signal Processing Toolbox	Filter order must be a constant. Expressions or variables are allowed if their values do not change.
`besseli`	MATLAB	• If the order `nu` is less than `0`, it must be an integer. • Always returns a complex result.
`besselj`	MATLAB	• If the order `nu` is less than `0`, it must be an integer. • Always returns a complex result.
`beta`	MATLAB	—
`betacdf`	Statistics and Machine Learning Toolbox	—
`betafit`	Statistics and Machine Learning Toolbox	—
`betainc`	MATLAB	Always returns a complex result.
`betaincinv`	MATLAB	Always returns a complex result.
`betainv`	Statistics and Machine Learning Toolbox	—
`betalike`	Statistics and Machine Learning Toolbox	—
`betaln`	MATLAB	—
`betapdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`betarnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`betastat`	Statistics and Machine Learning Toolbox	—
`bi2de`	Communications System Toolbox	—
`billingsleyicm`	Phased Array System Toolbox	Does not support variable-size inputs.
`bin2dec`	MATLAB	• Does not support cell arrays. • Does not match MATLAB when the input is empty.
`binocdf`	Statistics and Machine Learning Toolbox	—
`binoinv`	Statistics and Machine Learning Toolbox	—
`binopdf`	Statistics and Machine Learning Toolbox	—
`binornd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`binostat`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`bitand`	MATLAB	—
`bitand`	Fixed-Point Designer	• Not supported for slope-bias scaled `fi` objects.
`bitandreduce`	Fixed-Point Designer	—
`bitcmp`	MATLAB	—
`bitcmp`	Fixed-Point Designer	—
`bitconcat`	Fixed-Point Designer	—
`bitget`	MATLAB	—
`bitget`	Fixed-Point Designer	—
`bitor`	MATLAB	—
`bitor`	Fixed-Point Designer	• Not supported for slope-bias scaled `fi` objects.
`bitorreduce`	Fixed-Point Designer	—
`bitreplicate`	Fixed-Point Designer	—
`bitrevorder`	Signal Processing Toolbox	—
`bitrol`	Fixed-Point Designer	—
`bitror`	Fixed-Point Designer	—
`bitset`	MATLAB	—
`bitset`	Fixed-Point Designer	—
`bitshift`	MATLAB	—

Name	Product	Remarks and Limitations
`bitshift`	Fixed-Point Designer	—
`bitsliceget`	Fixed-Point Designer	—
`bitsll`	Fixed-Point Designer	• Generated code may not handle out of range shifting.
`bitsra`	Fixed-Point Designer	• Generated code may not handle out of range shifting.
`bitsrl`	Fixed-Point Designer	• Generated code may not handle out of range shifting.
`bitxor`	MATLAB	—
`bitxor`	Fixed-Point Designer	• Not supported for slope-bias scaled `fi` objects.
`bitxorreduce`	Fixed-Point Designer	—
`blackman`	Signal Processing Toolbox	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`blackmanharris`	Signal Processing Toolbox	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`blanks`	MATLAB	—
`blkdiag`	MATLAB	—
`bohmanwin`	Signal Processing Toolbox	Window length must be a constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`boundarymask`	Image Processing Toolbox	The `conn` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`break`	MATLAB	—
BRISKPoints	Computer Vision System Toolbox	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the "Introduction to Code Generation with Feature Matching and Registration" example.
`broadside2az`	Phased Array System Toolbox	Does not support variable-size inputs.
`bsxfun`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`buttap`	Signal Processing Toolbox	Filter order must be a constant. Expressions or variables are allowed if their values do not change.
`butter`	Signal Processing Toolbox	Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.
`buttord`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`bwareaopen`	Image Processing Toolbox	`BW` must be a 2-D binary image. N-D arrays are not supported. `conn` can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. `conn` must be a compile-time constant. MATLAB Function Block support: No.
`bwboundaries`	Image Processing Toolbox	The `conn` and `options` arguments must be compile-time constants and the return value `A` can only be a full matrix, not a sparse matrix. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`bwconncomp`	Image Processing Toolbox	The input image must be 2-D. The `conn` argument must be a compile-time constant and the only connectivities supported are 4 or 8. You can specify connectivity as a 3-by-3 matrix, but it can only be `[0 1 0;1 1 1;0 1 0]` or `ones(3)`. The `CC` struct return value does not include the `PixelIdxList` field. MATLAB Function Block support: No.
`bwdist`	Image Processing Toolbox	The `method` argument must be a compile-time constant. Input images must have fewer than 2^{32} pixels. Generated code for this function uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`bweuler`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwlabel`	Image Processing Toolbox	When generating code, the parameter `n` must be a compile-time constant. MATLAB Function Block support: No.
`bwlookup`	Image Processing Toolbox	For best results, specify an input image of class `logical`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwmorph`	Image Processing Toolbox	The text string specifying the operation must be a constant and, for best results, specify an input image of class `logical`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`bwpack`	Image Processing Toolbox	Generated code for this function uses a precompiled platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`bwperim`	Image Processing Toolbox	Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwselect`	Image Processing Toolbox	Supports only the 3 and 4 input argument syntaxes: `BW2 = bwselect(BW,c,r)` and `BW2 = bwselect(BW,c,r,n)`. The optional fourth input argument, `n`, must be a compile-time constant. In addition, with code generation, `bwselect` only supports only the 1 and 2 output argument syntaxes: `BW2 = bwselect(___)` or `[BW2, idx] = bwselect(___)`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwtraceboundary`	Image Processing Toolbox	The `dir`, `fstep`, and `conn` arguments must be compile-time constants. MATLAB Function Block support: No.
`bwunpack`	Image Processing Toolbox	Generated code for this function uses a precompiled platform-specific shared library. MATLAB Function Block support: Yes. The input argument `M` must be a compile-time constant.
`ca2tf`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`cameraMatrix`	Computer Vision System Toolbox	Supports MATLAB Function block: No
cameraParameters	Computer Vision System Toolbox	Supports MATLAB Function block: No
`cameraPose`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`cart2hom`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`cart2pol`	MATLAB	—
`cart2sph`	MATLAB	—
`cart2sphvec`	Phased Array System Toolbox	Does not support variable-size inputs.
`cast`	MATLAB	—
`cat`	MATLAB	• Does not support concatenation of cell arrays. • If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cbfweights`	Phased Array System Toolbox	Does not support variable-size inputs.
`cdf`	Statistics and Machine Learning Toolbox	—
`ceil`	MATLAB	—
`ceil`	Fixed-Point Designer	—
`cell`	MATLAB	"Cell Array Requirements and Limitations for Code Generation" on page 50-5
`cfirpm`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`char`	MATLAB	Does not support cell arrays.

Name	Product	Remarks and Limitations
`cheb1ap`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb1ord`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb2ap`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb2ord`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`chebwin`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheby1`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheby2`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`chi2cdf`	Statistics and Machine Learning Toolbox	—
`chi2inv`	Statistics and Machine Learning Toolbox	—
`chi2pdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`chi2rnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`chi2stat`	Statistics and Machine Learning Toolbox	—
`chol`	MATLAB	—
`circpol2pol`	Phased Array System Toolbox	Does not support variable-size inputs.
`circshift`	MATLAB	Does not support cell arrays for the first argument.
`cl2tf`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`class`	MATLAB	—
`colon`	MATLAB	• Does not accept complex inputs. • The input `i` cannot have a logical value. • Does not accept vector inputs. • Inputs must be constants. • Uses single-precision arithmetic to produce single-precision results.

comm.ViterbiDecoder	Communications System Toolbox	"System Objects in MATLAB Code Generation"
comm.WalshCode	Communications System Toolbox	"System Objects in MATLAB Code Generation"
`compan`	MATLAB	—
`complex`	MATLAB	—
`complex`	Fixed-Point Designer	—
compressor	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`computer`	MATLAB	• Information about the computer on which the code generation software is running. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`cond`	MATLAB	—
`conj`	MATLAB	—
`conj`	Fixed-Point Designer	—
`conndef`	Image Processing Toolbox	Input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`continue`	MATLAB	—
`conv`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Name	Product	Remarks and Limitations

`conv`	Fixed-Point Designer	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
		• For variable-sized signals, you may see different results between MATLAB and the generated code.
		  • In generated code, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath`.
		  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when both inputs are nonscalar. However, if either input is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

`conv2`	MATLAB	—
`convenc`	Communications System Toolbox	—
`convergent`	Fixed-Point Designer	—
`convn`	MATLAB	—
`cordicabs`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicangle`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicatan2`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordiccart2pol`	Fixed-Point Designer	• Variable-size signals are not supported.

Name	Product	Remarks and Limitations
`cordiccexp`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordiccos`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicpol2cart`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicrotate`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicsin`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicsincos`	Fixed-Point Designer	• Variable-size signals are not supported.
`cordicsqrt`	Fixed-Point Designer	• Variable-size signals are not supported.
cornerPoints	Computer Vision System Toolbox	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the "Introduction to Code Generation with Feature Matching and Registration" example.
`corrcoef`	MATLAB	• Row-vector input is only supported when the first two inputs are vectors and nonscalar.
`cos`	MATLAB	—
`cos`	Fixed-Point Designer	—
`cosd`	MATLAB	—
`cosh`	MATLAB	—
`cot`	MATLAB	—

Name	Product	Remarks and Limitations
`cotd`	MATLAB	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`coth`	MATLAB	—
`cov`	MATLAB	• If the input is variable-size and is `[]` at run time, returns `[]` not `NaN`. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cross`	MATLAB	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
crossoverFilter	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`csc`	MATLAB	—
`cscd`	MATLAB	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`csch`	MATLAB	—
`ctranspose`	MATLAB	—
`ctranspose`	Fixed-Point Designer	—
`cummin`	MATLAB	—
`cummax`	MATLAB	—
`cumprod`	MATLAB	Does not support logical inputs. Cast input to `double` first.
`cumsum`	MATLAB	Does not support logical inputs. Cast input to `double` first.

Name	Product	Remarks and Limitations
`cumtrapz`	MATLAB	—
`db2pow`	Signal Processing Toolbox	—
`dct`	Signal Processing Toolbox	• Code generation for this function requires the DSP System Toolbox software. • Length of transform dimension must be a power of two. If specified, the pad or truncation value must be constant. Expressions or variables are allowed if their values do not change.
`de2bi`	Communications System Toolbox	—
`deal`	MATLAB	—
`deblank`	MATLAB	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.
`dec2bin`	MATLAB	• If input `d` is `double`, `d` must be less than `2^52`. • If input `d` is `single`, `d` must be less than `2^23`. • Unless you specify input `n` to be constant and `n` is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, `n` must be at least `52` for `double`, `23` for `single`, `16` for `char`, `32` for `int32`, `16` for `int16`, and so on.

Name	Product	Remarks and Limitations
`dec2hex`	MATLAB	• If input `d` is `double`, `d` must be less than `2^52`. • If input `d` is `single`, `d` must be less than `2^23`. • Unless you specify input `n` to be constant, and `n` is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, `n` must be at least `13` for `double`, `6` for `single`, `4` for `char`, `8` for `int32`, `4` for `int16`, and so on.
`dechirp`	Phased Array System Toolbox	Does not support variable-size inputs.
`deconv`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`deg2rad`	MATLAB	—
`del2`	MATLAB	—
`delayseq`	Phased Array System Toolbox	Does not support variable-size inputs.
`demosaic`	Image Processing Toolbox	The `sensorAlignment` argument must be a compile-time constant. MATLAB Function Block support: Yes.
`depressionang`	Phased Array System Toolbox	Does not support variable-size inputs.
`designMultirateFIR`	DSP System Toolbox	The inputs to the function must be constants
`designParamEQ`	Audio System Toolbox	Supports MATLAB Function Block: Yes
`designShelvingEQ`	Audio System Toolbox	Supports MATLAB Function Block: Yes

Name	Product	Remarks and Limitations
`designVarSlopeFilter`	Audio System Toolbox	Supports MATLAB Function Block: Yes
`det`	MATLAB	—
`detectBRISKFeatures`	Computer Vision System Toolbox	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
`detectCheckerboard-Points`	Computer Vision System Toolbox	Supports MATLAB Function block: No Code generation will not support specifying images as file names or cell arrays of file names. It supports only checkerboard detection in a single image or stereo pair of images. For example, these syntaxes are supported: • `detectCheckerboardPoints(I1)` • `detectCheckerobarPoints(I1,I2)` `I1` and `I2` are single grayscale or RGB images.
`detectFASTFeatures`	Computer Vision System Toolbox	Supports MATLAB Function block: No Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"Generated code for this function uses a precompiled platform-specific shared library.
`detectHarrisFeatures`	Computer Vision System Toolbox	Compile-time constant input: `FilterSize` Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
`detectMinEigenFeatures`	Computer Vision System Toolbox	Compile-time constant input: `FilterSize` Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.

Name	Product	Remarks and Limitations
`detectMSERFeatures`	Computer Vision System Toolbox	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries "Portable C Code Generation for Functions That Use OpenCV Library" For code generation, the function outputs `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`.
`detectSURFFeatures`	Computer Vision System Toolbox	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"

`detrend`	MATLAB	• If supplied and not empty, the input argument `bp` must satisfy the following requirements:
		  • Be real.
		  • Be sorted in ascending order.
		  • Restrict elements to integers in the interval `[1, n-2]`. `n` is the number of elements in a column of input argument `X`, or the number of elements in `X` when `X` is a row vector.
		  • Contain all unique values.
		  • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Name	Product	Remarks and Limitations

`diag`	MATLAB	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
		• For variable-size inputs that are variable-length vectors (1-by-: or :-by-1), `diag`:
		  • Treats the input as a vector input.
		  • Returns a matrix with the given vector along the specified diagonal.
		• For variable-size inputs that are not variable-length vectors, `diag`:
		  • Treats the input as a matrix.
		  • Does not support inputs that are vectors at run time.
		  • Returns a variable-length vector.
		  If the input is variable-size (:m-by-:n) and has shape 0-by-0 at run time, the output is 0-by-1 not 0-by-0. However, if the input is a constant size 0-by-0, the output is `[]`.
		• For variable-size inputs that are not variable-length vectors (1-by-: or :-by-1), `diag` treats the input as a matrix from which to extract a diagonal vector. This behavior occurs even if the input array is a vector at run time. To force `diag` to build a matrix from variable-size inputs that are not 1-by-: or :-by-1, use:
		  • `diag(x(:))` instead of `diag(x)`
		  • `diag(x(:),k)` instead of `diag(x,k)`
		• "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Name	Product	Remarks and Limitations
`diag`	Fixed-Point Designer	• If supplied, the index, *k*, must be a real and scalar integer value that is not a `fi` object.
`diff`	MATLAB	• If supplied, the arguments representing the number of times to apply `diff` and the dimension along which to calculate the difference must be constants. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`disparity`	Computer Vision System Toolbox	Compile-time constant input restriction: `'Method'`. Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
`divide`	Fixed-Point Designer	• Any non-`fi` input must be constant. Its value must be known at compile time so that it can be cast to a `fi` object. • Complex and imaginary divisors are not supported. • The syntax `T.divide(a,b)` is not supported.
`dop2speed`	Phased Array System Toolbox	Does not support variable-size inputs.
`dopsteeringvec`	Phased Array System Toolbox	Does not support variable-size inputs.
`dot`	MATLAB	—
`double`	MATLAB	—
`double`	Fixed-Point Designer	—
`downsample`	Signal Processing Toolbox	—

Name	Product	Remarks and Limitations
`dpskdemod`	Communications System Toolbox	—
`dpskmod`	Communications System Toolbox	—
`dpss`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
dsp.AdaptiveLatticeFilter	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.AffineProjectionFilter	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.AllpassFilter	DSP System Toolbox	"System Objects in MATLAB Code Generation" The System object supports code generation only when the `Structure` property is set to `Minimum multiplier` or `Lattice`.
dsp.AllpoleFilter	DSP System Toolbox	• "System Objects in MATLAB Code Generation" • Only the `Denominator` property is tunable for code generation.
dsp.AnalyticSignal	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.ArrayPlot	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.ArrayVectorAdder	DSP System Toolbox	"System Objects in MATLAB Code Generation"

dsp.VectorQuantizerDecoder	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.VectorQuantizerEncoder	DSP System Toolbox	"System Objects in MATLAB Code Generation"
dsp.Window	DSP System Toolbox	• This object has no tunable properties for code generation. • "System Objects in MATLAB Code Generation"

Name	Product	Remarks and Limitations
dsp.ZeroCrossingDetector	DSP System Toolbox	"System Objects in MATLAB Code Generation"
`edge`	Image Processing Toolbox	The `method`, `direction`, and `sigma` arguments must be a compile-time constants. In addition, nonprogrammatic syntaxes are not supported. For example, the syntax `edge(im)`, where `edge` does not return a value but displays an image instead, is not supported. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input arguments `thresh` and `sigma` must be compile-time constants.
`effearthradius`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`eig`	MATLAB	• For code generation,`QZ` algorithm is used in all cases. MATLAB can use different algorithms for different inputs. Consequently, `V` might represent a different basis of eigenvectors. The eigenvalues in `D` might not be in the same order as in MATLAB. • With one input, `[V,D] = eig(A)`, the results are similar to those obtained using `[V,D] = eig(A,eye(size(A)),'qz')` in MATLAB, except that the columns of `V` are normalized. • Options `'balance'`, and `'nobalance'` are not supported for the standard eigenvalue problem. `'chol'` is not supported for the symmetric generalized eigenvalue problem. • Outputs are of complex type. • Does not support the option to calculate left eigenvectors.
`ellip`	Signal Processing Toolbox	Inputs must be constant. Expressions or variables are allowed if their values do not change.
`ellipap`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`ellipke`	MATLAB	—
`ellipord`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`end`	MATLAB	—
`end`	Fixed-Point Designer	—
`epipolarLine`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes

Name	Product	Remarks and Limitations
`eps`	MATLAB	—
`eps`	Fixed-Point Designer	• Supported for scalar fixed-point signals only. • Supported for scalar, vector, and matrix, `fi` single and `fi` double signals.
`eq`	MATLAB	—
`eq`	Fixed-Point Designer	Not supported for fixed-point signals with different biases.
`erf`	MATLAB	—
`erfc`	MATLAB	—
`erfcinv`	MATLAB	—
`erfcx`	MATLAB	—
`erfinv`	MATLAB	—
`error`	MATLAB	For standalone code generation, excluded from the generated code.
`espritdoa`	Phased Array System Toolbox	Does not support variable-size inputs.
`estimateFundamental-Matrix`	Computer Vision System Toolbox	Compile-time constant input: `Method`, `OutputClass`, `DistanceType`, and `ReportRuntimeError`. Supports MATLAB Function block: Yes
`estimateGeometric-Transform`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`estimateUncalibrated-Rectification`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
`eul2quat`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`eul2rotm`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`eul2tform`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes

Name	Product	Remarks and Limitations
`evcdf`	Statistics and Machine Learning Toolbox	—
`evinv`	Statistics and Machine Learning Toolbox	—
`evpdf`	Statistics and Machine Learning Toolbox	—
`evrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`evstat`	Statistics and Machine Learning Toolbox	—
`exp`	MATLAB	—
expander	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`expcdf`	Statistics and Machine Learning Toolbox	—
`expint`	MATLAB	—
`expinv`	Statistics and Machine Learning Toolbox	—
`expm`	MATLAB	—
`expm1`	MATLAB	—

Name	Product	Remarks and Limitations
`exppdf`	Statistics and Machine Learning Toolbox	—
`exprnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`expstat`	Statistics and Machine Learning Toolbox	—
`extractFeatures`	Computer Vision System Toolbox	Compile-time constant input restrictions: `'Method'` Supports MATLAB Function block: Yes for `Block` method only. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries for `BRISK`, `FREAK`, and `SURF` Methods. "Portable C Code Generation for Functions That Use OpenCV Library"
`extractHOGFeatures`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`extractLBPFeatures`	Computer Vision System Toolbox	Generates platform-dependent library: No Supports MATLAB Function block: Yes
`extrinsics`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`eye`	MATLAB	• `classname` must be a built-in MATLAB numeric type. Does not invoke the static `eye` method for other classes. For example, `eye(m, n, 'myclass')` does not invoke `myclass.eye(m,n)`. • Size arguments must have a fixed size.

Name	Product	Remarks and Limitations
`factor`	MATLAB	• The maximum double precision input is `2^33`. • The maximum single precision input is `2^25`. • The input `n` cannot have type `int64` or `uint64`.
`factorial`	MATLAB	—
`false`	MATLAB	• Dimensions must be real, nonnegative, integers.
`fcdf`	Statistics and Machine Learning Toolbox	—
`fclose`	MATLAB	—
`feof`	MATLAB	—
`fft`	MATLAB	• "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`fft2`	MATLAB	—
`fftn`	MATLAB	The `siz` argument must have a fixed size.
`fftshift`	MATLAB	—

Name	Product	Remarks and Limitations
`fi`	Fixed-Point Designer	• Use to create a fixed-point constant or variable. • The default constructor syntax without input arguments is not supported. • The rand `fi('PropertyName',PropertyValue...)` is not supported. To use property name/property value pairs, you must first specify the value `v` of the `fi` object as in `fi(v,'PropertyName',PropertyValue...)`. • If the input value is not known at compile time, you must provide complete `numerictype` information. • All properties related to data type must be constant for code generation. • `numerictype` object information must be available for non-fixed-point Simulink inputs.
`fieldnames`	MATLAB	Does not support objects. The input must be a structure.
`filter`	MATLAB	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`filter`	Fixed-Point Designer	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
`filter2`	MATLAB	—
`filtfilt`	Signal Processing Toolbox	Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`fimath`	Fixed-Point Designer	• Fixed-point signals coming in to a `MATLAB Function` block from Simulink are assigned the `fimath` object defined in the MATLAB Function dialog in the Model Explorer. • Use to create `fimath` objects in generated code. • If the `ProductMode` property of the `fimath` object is set to anything other than `FullPrecision`, the `ProductWordLength` and `ProductFractionLength` properties must be constant. • If the `SumMode` property of the `fimath` object is set to anything other than `FullPrecision`, the `SumWordLength` and `SumFractionLength` properties must be constant.

Name	Product	Remarks and Limitations
`find`	MATLAB	• Issues an error if a variable-size input becomes a row vector at run time. **Note:** This limitation does not apply when the input is scalar or a variable-length row vector. • For variable-size inputs, the shape of empty outputs, 0-by-0, 0-by-1, or 1-by-0, depends on the upper bounds of the size of the input. The output might not match MATLAB when the input array is a scalar or [] at run time. If the input is a variable-length row vector, the size of an empty output is 1-by-0, otherwise it is 0-by-1. • Always returns a variable-length vector. Even when you provide the output vector `k`, the output cannot be fixed-size because the output can contain fewer than k elements. For example, `find(x,1)` returns a variable-length vector with 1 or 0 elements.
`findpeaks`	Signal Processing Toolbox	—
`finv`	Statistics and Machine Learning Toolbox	—
`fir1`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fir2`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firceqrip`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`fircls`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fircls1`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fireqint`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firgr`	DSP System Toolbox	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`firhalfband`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firlpnorm`	DSP System Toolbox	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`firls`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firminphase`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firnyquist`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firpr2chfb`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`firpm`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firpmord`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fitgeotrans`	Image Processing Toolbox	The `transformtype` argument must be a compile-time constant. The function supports the following transformation types: `'nonreflectivesimilarity'`, `'similarity'`, `'affine'`, or `'projective'`. MATLAB Function Block support: Yes.
`fix`	MATLAB	—
`fix`	Fixed-Point Designer	—
`fixed.Quantizer`	Fixed-Point Designer	—
`flattopwin`	Signal Processing Toolbox	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`flintmax`	MATLAB	—
`flip`	MATLAB	Does not support cell arrays for the first argument.
`flip`	Fixed-Point Designer	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`flipdim`	MATLAB	Does not support cell arrays for the first argument.
`fliplr`	MATLAB	Does not support cell arrays.
`fliplr`	Fixed-Point Designer	—
`flipud`	MATLAB	Does not support cell arrays.

Name	Product	Remarks and Limitations
`flipud`	Fixed-Point Designer	—
`floor`	MATLAB	—
`floor`	Fixed-Point Designer	—
`fminsearch`	MATLAB	• Ignores the `Display` option. Does not print status information during execution. Test the `exitflag` output for the exit condition. • The output structure does not include the `algorithm` or `message` fields. • Ignores the `OutputFcn` and `PlotFcns` options.
`fogpl`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations

`fopen`	MATLAB	• Does not support:
		  • `machineformat`, `encoding`, or `fileID` inputs
		  • `message` output
		  • `fopen('all')`
		• If you disable extrinsic calls, you cannot return `fileID`s created with `fopen` to MATLAB or extrinsic functions. You can use such `fileID`s only internally.
		• When generating C/C++ executables, static libraries, or dynamic libraries, you can open up to 20 files.
		• The generated code does not report errors from invalid file identifiers. Write your own file open error handling in your MATLAB code. Test whether `fopen` returns `-1`, which indicates that the file open failed. For example:
		`...`
		`fid = fopen(filename, 'r');`
		`if fid == -1`
		`  % fopen failed`
		`else`
		`% fopen successful, okay to call fread`
		`A = fread(fid);`
		`...`
		• The behavior of the generated code for `fread` is compiler-dependent if you:
		1 Open a file using `fopen` with a `permission` of `a+`.
		2 Read the file using `fread` before calling an I/O function, such as `fseek` or

Name	Product	Remarks and Limitations
		`frewind`, that sets the file position indicator.
`for`	MATLAB	—
`for`	Fixed-Point Designer	—
`fpdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations

`fprintf`	MATLAB	• Does not support:
		  • `b` and `t` subtypes on `%u`, `%o` `%x`, and `%X` formats.
		  • `$` flag for reusing input arguments.
		  • printing arrays.
		• There is no automatic casting. Input arguments must match their format types for predictable results.
		• Escaped characters are limited to the decimal range of 0–127.
		• A call to `fprintf` with `fileID` equal to `1` or `2` becomes `printf` in the generated C/C++ code in the following cases:
		  • The `fprintf` call is inside a `parfor` loop.
		  • Extrinsic calls are disabled.
		• When the MATLAB behavior differs from the C compiler behavior, `fprintf` matches the C compiler behavior in the following cases:
		  • The format specifier has a corresponding C format specifier, for example, `%e` or `%E`.
		  • The `fprintf` call is inside a `parfor` loop.
		  • Extrinsic calls are disabled.
		• When you call `fprintf` with the format specifier `%s`, do not put a null character in the middle of the input string. Use `fprintf(fid, '%c', char(0))` to write a null character.
		• When you call `fprintf` with an integer format specifier, the type of the integer argument must be a type that the target hardware can represent as a native C type. For example, if you call `fprintf('%d',`

Name	Product	Remarks and Limitations
		`int64(n)`, the target hardware must have a native C type that supports a 64-bit integer.

Name	Product	Remarks and Limitations

`fread`	MATLAB	• `precision` must be a constant.
		• The `source` and `output` that `precision` specifies cannot have values `long`, `ulong`, `unsigned long`, `bitN`, or `ubitN`.
		• You cannot use the `machineformat` input.
		• If the `source` or `output` that `precision` specifies is a C type, for example, `int`, the target and production sizes for that type must:
		  • Match.
		  • Map directly to a MATLAB type.
		• The `source` type that `precision` specifies must map directly to a C type on the target hardware.
		• If the `fread` call reads the entire file, all of the data must fit in the largest array available for code generation.
		• If `sizeA` is not constant or contains a nonfinite element, then dynamic memory allocation is required.
		• Treats a `char` value for `source` or `output` as a signed 8-bit integer. Use values between 0 and 127 only.
		• The generated code does not report file read errors. Write your own file read error handling in your MATLAB code. Test that the number of bytes read matches the number of bytes that you requested. For example:
		`...`
		`N = 100;`
		`[vals, numRead] = fread(fid, N, '*double');`
		`if numRead ~= N`
		`  % fewer elements read than expected`

Name	Product	Remarks and Limitations
		`end` `...`
`freqspace`	MATLAB	—
`freqz`	Signal Processing Toolbox	• Does not support variable-size inputs. • When called with no output arguments, and without a semicolon at the end, `freqz` returns the complex frequency response of the input filter, evaluated at 512 points. If the semicolon is added, the function produces a plot of the magnitude and phase response of the filter. See “freqz With No Output Arguments”.
`frewind`	MATLAB	—
`frnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`fspecial`	Image Processing Toolbox	Inputs must be compile-time constants. Expressions or variables are allowed if their values do not change. MATLAB Function Block support: Yes. The input arguments `hsize`, `radius`, `len`, and `theta` must be compile-time constants.
`fspl`	Phased Array System Toolbox	Does not support variable-size inputs.
`fstat`	Statistics and Machine Learning Toolbox	—
`full`	MATLAB	—

Name	Product	Remarks and Limitations
`fzero`	MATLAB	• The first argument must be a function handle. Does not support structure, inline function, or string inputs for the first argument. • Supports up to three output arguments. Does not support the fourth output argument (the `output` structure).
`gain2aperture`	Phased Array System Toolbox	Does not support variable-size inputs.
`gamcdf`	Statistics and Machine Learning Toolbox	—
`gaminv`	Statistics and Machine Learning Toolbox	—
`gamma`	MATLAB	—
`gammainc`	MATLAB	Output is always complex.
`gammaincinv`	MATLAB	Output is always complex.
`gammaln`	MATLAB	—
`gampdf`	Statistics and Machine Learning Toolbox	—
`gamrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`gamstat`	Statistics and Machine Learning Toolbox	—
`gaspl`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`gausswin`	Signal Processing Toolbox	All`gaspl` inputs must be constant. Expressions or variables are allowed if their values do not change.
`gccphat`	Phased Array System Toolbox	Does not support variable-size inputs.
`gcd`	MATLAB	—
`ge`	MATLAB	—
`ge`	Fixed-Point Designer	• Not supported for fixed-point signals with different biases.
`generateCheckerboard-Points`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`geocdf`	Statistics and Machine Learning Toolbox	—
`geoinv`	Statistics and Machine Learning Toolbox	—
`geomean`	Statistics and Machine Learning Toolbox	—
`geopdf`	Statistics and Machine Learning Toolbox	—
`geornd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`geostat`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`get`	Fixed-Point Designer	• The syntax `structure = get(o)` is not supported.
`getlsb`	Fixed-Point Designer	—
`getmsb`	Fixed-Point Designer	—
`getrangefromclass`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`gevcdf`	Statistics and Machine Learning Toolbox	—
`gevinv`	Statistics and Machine Learning Toolbox	—
`gevpdf`	Statistics and Machine Learning Toolbox	—
`gevrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`gevstat`	Statistics and Machine Learning Toolbox	—
`global2localcoord`	Phased Array System Toolbox	Does not support variable-size inputs.
`gpcdf`	Statistics and Machine Learning Toolbox	—
`gpinv`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`gppdf`	Statistics and Machine Learning Toolbox	—
`gprnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`gpstat`	Statistics and Machine Learning Toolbox	—
`gradient`	MATLAB	—
`grayconnected`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`grazingang`	Phased Array System Toolbox	Does not support variable-size inputs.
`gt`	MATLAB	—
`gt`	Fixed-Point Designer	• Not supported for fixed-point signals with different biases.
`hadamard`	MATLAB	`n` must be a fixed-size scalar.
`hamming`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`hankel`	MATLAB	—
`hann`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
`harmmean`	Statistics and Machine Learning Toolbox	—
hdl.RAM	MATLAB	—
`hex2dec`	MATLAB	Does not support cell arrays.
`hex2num`	MATLAB	• Does not support cell arrays. • For `n = hex2num(S)`, `size(S,2) <= length(num2hex(0))`
`hilb`	MATLAB	—

Name	Product	Remarks and Limitations

`hist`	MATLAB	• Histogram bar plotting not supported. Call with at least one output argument.
		• If supplied, the second argument `x` must be a scalar constant.
		• Inputs must be real.
		For the syntax `[nout, xout] = hist(y,x)`:
		• When `y` is a fixed-size vector or variable-length vector:
		  • `nout` is always a row vector.
		  • If `x` is a vector, `xout` is a vector with the same orientation as `x`.
		  • If `x` is a scalar (fixed-size), `xout` is a row vector.
		• `nout` and `xout` are column vectors when the following conditions are true:
		  • `y` is a matrix
		  • `size(y,1)` and `size(y,2)` do not have fixed length 1
		  • One of `size(y,1)` and `size(y,2)` has length 1 at run time
		• A variable-size `x` is interpreted as a vector input even if it is a scalar at run time.
		• If at least one of the inputs is empty, vector orientations in the output can differ from MATLAB.

Name	Product	Remarks and Limitations
`histc`	MATLAB	• The output of a variable-size array that becomes a column vector at run time is a column-vector, not a row-vector. • If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`histeq`	Image Processing Toolbox	All the syntaxes that include indexed images are not supported. This includes all syntaxes that accept `map` as input and return `newmap`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be a compile-time constant.
`hom2cart`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`horizonrange`	Phased Array System Toolbox	Does not support variable-size inputs.
`horzcat`	Fixed-Point Designer	—
`hough`	Image Processing Toolbox	The optional parameter names `'Theta'` and `'RhoResolution'` must be compile-time string constants. The optional `Theta` vector must have a bounded size. MATLAB Function Block support: Yes. The input argument `BW` must be fixed size, the `RhoResolution` parameter must be a compile-time constant, and the `Theta` vector must have a bounded size.

Name	Product	Remarks and Limitations
`houghlines`	Image Processing Toolbox	The optional parameter names `'FillGap'` and `'MinLength'` must be compile-time string constants. Their associated values need not be compile-time constants. MATLAB Function Block support: No.
`houghpeaks`	Image Processing Toolbox	The optional parameter names `'Threshold'` and `'NHoodSize'` must be compile-time string constants. Their associated values need not be compile-time constants. MATLAB Function Block support: Yes.
`hygecdf`	Statistics and Machine Learning Toolbox	—
`hygeinv`	Statistics and Machine Learning Toolbox	—
`hygepdf`	Statistics and Machine Learning Toolbox	—
`hygernd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`hygestat`	Statistics and Machine Learning Toolbox	—
`hypot`	MATLAB	—
`icdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`idct`	Signal Processing Toolbox	• Code generation for this function requires the DSP System Toolbox software. • Length of transform dimension must be a power of two. If specified, the pad or truncation value must be constant. Expressions or variables are allowed if their values do not change.
`if, elseif, else`	MATLAB	—
`idivide`	MATLAB	• For efficient generated code, MATLAB rules for divide by zero are supported only for the `'round'` option.
`ifft`	MATLAB	• Output is complex. • Does not support the `'symmetric'` option. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`ifft2`	MATLAB	• Does not support the `'symmetric'` option.
`ifftn`	MATLAB	• Does not support the `'symmetric'` option. • The `siz` argument must have a fixed size.
`ifftshift`	MATLAB	—
`ifir`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iircomb`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iirgrpdelay`	DSP System Toolbox	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.

Name	Product	Remarks and Limitations
`iirlpnorm`	DSP System Toolbox	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`iirlpnormc`	DSP System Toolbox	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`iirnotch`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iirpeak`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`im2double`	MATLAB	MATLAB Function Block support: Yes.
`im2int16`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`im2single`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`im2uint8`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`im2uint16`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imabsdiff`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`imadjust`	Image Processing Toolbox	Does not support syntaxes that include indexed images. This includes all syntaxes that accept `map` as input and return `newmap`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imag`	MATLAB	—
`imag`	Fixed-Point Designer	—
`imaq.VideoDevice`	Image Acquisition Toolbox™	"Code Generation with VideoDevice System Object"
`imbinarize`	Image Processing Toolbox	String input arguments must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imbothat`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imboxfilt`	Image Processing Toolbox	MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imclearborder`	Image Processing Toolbox	The optional second input argument, `conn`, must be a compile-time constant. Supports only up to 3-D inputs. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imclose`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imcomplement`	Image Processing Toolbox	Does not support `int64` and `uint64` data types. MATLAB Function Block support: Yes.
`imcrop`	Image Processing Toolbox	The interactive syntaxes, such as `I2 = imcrop`, are not supported. Indexed images are not supported, including the noninteractive syntax `X2 = imcrop(X,map,rect);`. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imdilate`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The `SE`, `PACKOPT`, and `SHAPE` input arguments must be a compile-time constant. The structuring element argument `SE` must be a single element—arrays of structuring elements are not supported. To obtain the same result as that obtained using an array of structuring elements, call the function sequentially. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imerode`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The `SE`, `PACKOPT`, and `SHAPE` input arguments must be a compile-time constant. The structuring element argument `SE` must be a single element—arrays of structuring elements are not supported. To obtain the same result as that obtained using an array of structuring elements, call the function sequentially. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imextendedmax`	Image Processing Toolbox	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imextendedmin`	Image Processing Toolbox	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imfill`	Image Processing Toolbox	The optional input connectivity, `conn` and the string `'holes'` must be compile-time constants. Supports only up to 3-D inputs. The interactive mode to select points, `imfill(BW,0,CONN)` is not supported in code generation. `locations` can be a *P*-by-1 vector, in which case it contains the linear indices of the starting locations. `locations` can also be a *P*-by-`ndims(I)` matrix, in which case each row contains the array indices of one of the starting locations. Once you select a format at compile-time, you cannot change it at run time. However, the number of points in locations can be varied at run time. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imfilter`	Image Processing Toolbox	The input image can be either 2-D or 3-D. The value of the input argument, `options`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imfindcircles`	Image Processing Toolbox	All string input arguments and values must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`imgaborfilt`	Image Processing Toolbox	MATLAB Function Block support: No.
`imgaussfilt`	Image Processing Toolbox	String input arguments must be compile-time constants. When `FilterDomain` is `'spatial'`, if you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imgradient3`	Image Processing Toolbox	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`imgradientxyz`	Image Processing Toolbox	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imhist`	Image Processing Toolbox	The optional second input argument, `n`, must be a compile-time constant. In addition, nonprogrammatic syntaxes are not supported. For example, the syntaxes where `imhist` displays the histogram are not supported. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be a compile-time constant.
`imhmax`	Image Processing Toolbox	The optional third input argument, `conn`, must be a compile-time constant If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imhmin`	Image Processing Toolbox	The optional third input argument, `conn`, must be a compile-time constant If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imlincomb`	Image Processing Toolbox	The `output_class` argument must be a compile-time constant. You can specify up to four input image arguments. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`immse`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`imopen`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imoverlay`	Image Processing Toolbox	If you specify the `'color'` argument as a string, it must be a compile-time constant. MATLAB Function Block support: Yes.
`impyramid`	Image Processing Toolbox	The `direction` argument must be a compile-time constant. MATLAB Function Block support: Yes. The input argument direction must be a compile-time constant.
`imquantize`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`imread`	Image Processing Toolbox	Supports reading of 8-bit JPEG images only. The file name input argument must be a valid absolute path or relative path. This function generates code that uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The file name input argument must be a compile-time constant.

Name	Product	Remarks and Limitations
`imreconstruct`	Image Processing Toolbox	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
imref2d	Image Processing Toolbox	The `XWorldLimits`, `YWorldLimits` and `ImageSize` properties can be set only during object construction. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
imref3d	Image Processing Toolbox	The `XWorldLimits`, `YWorldLimits`, `ZWorldLimits` and `ImageSize` properties can be set only during object construction. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`imregionalmax`	Image Processing Toolbox	The optional second input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imregionalmin`	Image Processing Toolbox	The optional second input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imresize`	Image Processing Toolbox	Does not support indexed images or custom interpolation kernels. All parameter-value pair input arguments must be compile-time constants. MATLAB Function Block support: Yes. The input arguments `Scale` and `method` must be compile-time constants, and the values of the `OutputSize` parameter, `numrows` and `numcols`, must be compile-time constants.
`imrotate`	Image Processing Toolbox	The `method` and `bbox` input argument values must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `angle` must be a compile-time constant.
`imtophat`	Image Processing Toolbox	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Name	Product	Remarks and Limitations
`imtranslate`	Image Processing Toolbox	The supports only 2-D translation vectors. 3-D translations are not supported If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `translation` must be a compile-time constant.
`imwarp`	Image Processing Toolbox	The geometric transformation object input, `tform`, must be either `affine2d` or `projective2d`. Additionally, the interpolation method and optional parameter names must be string constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `tform` must be a compile-time constant.
`ind2sub`	MATLAB	• The first argument should be a valid size vector. Size vectors for arrays with more than `intmax` elements are not supported. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`inf`	MATLAB	• Dimensions must be real, nonnegative, integers.
`insertMarker`	Computer Vision System Toolbox	Compile-time constant input: `'Shape'` and `'Color'` Supports MATLAB Function block: Yes

Name	Product	Remarks and Limitations
`insertObjectAnnotation`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes Limitation: Input image must be bounded, see "Specify Variable-Size Data Without Dynamic Memory Allocation" on page 48-5 "System Objects in MATLAB Code Generation"
`insertShape`	Computer Vision System Toolbox	Compile-time constant input: `'Color'` and `'SmoothEdges'` Supports MATLAB Function block: Yes
`insertText`	Computer Vision System Toolbox	Compile-time constant input: `Font`, `FontSize` Supports non-ASCII characters: No Supports MATLAB Function block: Yes
`int8`, `int16`, `int32`, `int64`	MATLAB	—
`int8`, `int16`, `int32`, `int64`	Fixed-Point Designer	—
`integralBoxFilter`	Image Processing Toolbox	The `'NormalizationFactor'` parameter must be a compile-time constant. MATLAB Function Block support: Yes. The input argument `filtersize` must be a compile-time constant.
`integralImage`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes

Name	Product	Remarks and Limitations
`interp1`	MATLAB	• Does not support the `'cubic'` method. Instead, use `'v5cubic'` or `'spline'`. • The input argument `x` (sample points) must be strictly increasing or strictly decreasing. Indices are not reordered. • If the input argument `v` (sample values) is a variable-length vector (1-by-`:` or `:`-by-1), the shape of the output `vq` matches the shape in MATLAB. If the input argument `v` is variable-size, is not a variable-length vector, and becomes a row vector at run time, an error occurs. • If the input argument `xq` (query points) is variable-size, is not a variable-length vector, and becomes a row or column vector at run time, an error occurs. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`interp1q`	MATLAB	Might not match MATLAB when some `Y` values are `Inf` or `NaN`.

Name	Product	Remarks and Limitations

`interp2`	MATLAB	• `Xq` and `Yq` must be the same size. Use `meshgrid` to evaluate on a grid.
		• For best results, provide `X` and `Y` as vectors.
		• For the `'cubic'` method, reports an error if the grid does not have uniform spacing. In this case, use the `'spline'` method.
		• For best results when you use the `'spline'` method:
		  • Use `meshgrid` to create the inputs `Xq` and `Yq`.
		  • Use a small number of interpolation points relative to the dimensions of `V`. Interpolating over a large set of scattered points can be inefficient.

`interp3`	MATLAB	• `Xq`, `Yq`, and `Zq` must be the same size. Use `meshgrid` to evaluate on a grid.
		• For best results, provide `X`, `Y`, and `Z` as vectors.
		• For the `'cubic'` method, reports an error if the grid does not have uniform spacing. In this case, use the `'spline'` method.
		• For best results when you use the `'spline'` method:
		  • Use `meshgrid` to create the inputs `Xq`, `Yq`, and `Zq`.
		  • Use a small number of interpolation points relative to the dimensions of `V`. Interpolating over a large set of scattered points can be inefficient.

Name	Product	Remarks and Limitations
`interpn`	MATLAB	• For best results, provide `X1,X2,...,Xn` as vectors. • Does not support the `'cubic'` or `'spline'` methods for 2-D and higher interpolation. • The interpolation method must be a constant string.

Name	Product	Remarks and Limitations

`intersect`	MATLAB	• Does not support cell arrays for the first or second arguments.
		• When you do not specify the `'rows'` option:
		  • Inputs `A` and `B` must be vectors. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
		  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
		  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
		  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
		• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
		• When the `setOrder` is `'sorted'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
		• Complex inputs must be `single` or `double`.
		• When one input is complex and the other input is real, do one of the following:
		  • Set `setOrder` to `'stable'`.
		  • Sort the real input in complex ascending order (by absolute value). Suppose the real input

Name	Product	Remarks and Limitations
		is `x`. Use `sort(complex(x))` or `sortrows(complex(x))`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`intfilt`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`intlut`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`intmax`	MATLAB	—
`intmin`	MATLAB	—
`inv`	MATLAB	Singular matrix inputs can produce nonfinite values that differ from MATLAB results.
`invhilb`	MATLAB	—
`ipermute`	MATLAB	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`ipermute`	Fixed-Point Designer	—
`iptcheckconn`	Image Processing Toolbox	Input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`iptcheckmap`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`iqcoef2imbal`	Communications System Toolbox	—

Name	Product	Remarks and Limitations
`iqimbal2coef`	Communications System Toolbox	—
`iqr`	Statistics and Machine Learning Toolbox	—
`isa`	MATLAB	—
`isbanded`	MATLAB	—
`iscell`	MATLAB	—
`iscellstr`	MATLAB	—
`ischar`	MATLAB	—
`iscolumn`	MATLAB	—
`iscolumn`	Fixed-Point Designer	—
`isdeployed`	MATLAB Compiler	• Returns true and false as appropriate for MEX and SIM targets • Returns false for other targets
`isdiag`	MATLAB	—
`isempty`	MATLAB	—
`isempty`	Fixed-Point Designer	—
`isEpipoleInImage`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
`isequal`	MATLAB	—
`isequal`	Fixed-Point Designer	—
`isequaln`	MATLAB	—
`isfi`	Fixed-Point Designer	—
`isfield`	MATLAB	• Does not support cell arrays for the second argument

Name	Product	Remarks and Limitations
`isfimath`	Fixed-Point Designer	—
`isfimathlocal`	Fixed-Point Designer	—
`isfinite`	MATLAB	—
`isfinite`	Fixed-Point Designer	—
`isfloat`	MATLAB	—
`ishermitian`	MATLAB	—
`isinf`	MATLAB	—
`isinf`	Fixed-Point Designer	—
`isinteger`	MATLAB	—
`isletter`	MATLAB	• Input values from the `char` class must be in the range 0-127.
`islogical`	MATLAB	—
`ismac`	MATLAB	• Returns true or false based on the MATLAB version used for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`ismatrix`	MATLAB	—
`ismcc`	MATLAB Compiler	• Returns true and false as appropriate for MEX and SIM targets. • Returns false for other targets.
`ismember`	MATLAB	• Does not support cell arrays for the first or second arguments. • Complex inputs must be `single` or `double`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`isnan`	MATLAB	—

Name	Product	Remarks and Limitations
`isnan`	Fixed-Point Designer	—
`isnumeric`	MATLAB	—
`isnumeric`	Fixed-Point Designer	—
`isnumerictype`	Fixed-Point Designer	—
`isobject`	MATLAB	—
`ispc`	MATLAB	• Returns true or false based on the MATLAB version you use for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`isprime`	MATLAB	• The maximum double precision input is `2^33`. • The maximum single precision input is `2^25`. • The input `X` cannot have type `int64` or `uint64`.
`isreal`	MATLAB	—
`isreal`	Fixed-Point Designer	—
`isrow`	MATLAB	—
`isrow`	Fixed-Point Designer	—
`isscalar`	MATLAB	—
`isscalar`	Fixed-Point Designer	—
`issigned`	Fixed-Point Designer	—

Name	Product	Remarks and Limitations
`issorted`	MATLAB	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`isspace`	MATLAB	• Input values from the `char` class must be in the range 0–127.
`issparse`	MATLAB	—
`isstrprop`	MATLAB	• Supports only inputs from `char` and `integer` classes. • Input values must be in the range 0-127.
`isstruct`	MATLAB	—
`issymmetric`	MATLAB	—
`istrellis`	Communications System Toolbox	—
`istril`	MATLAB	—
`istriu`	MATLAB	—
`isunix`	MATLAB	• Returns true or false based on the MATLAB version used for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`isvector`	MATLAB	—
`isvector`	Fixed-Point Designer	—
`kaiser`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`kaiserord`	Signal Processing Toolbox	—

Name	Product	Remarks and Limitations
`kron`	MATLAB	—
`kmeans`	Statistics and Machine Learning Toolbox	• If the `Start` method uses random selections, the initial centroid cluster positions might not match MATLAB. • If the number of rows in `X` is fixed, does not remove rows of `X` that contain a `NaN`. • The cluster centroid locations in `C` can have a different order than in MATLAB. In this case, the cluster indices in `idx` have corresponding differences. • If you provide `Display`, its value must be `'off'`. • If you provide `Streams`, it must be empty and `UseSubstreams` must be `false`. • When you set the `UseParallel` option to `true`, some computations can execute in parallel even when `Replicates` is `1`. For large data sets, when `Replicates` is `1`, consider setting the `UseParallel` option to `true`.
`kurtosis`	Statistics and Machine Learning Toolbox	—
`lab2rgb`	Image Processing Toolbox	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`label2idx`	Image Processing Toolbox	MATLAB Function Block support: No.

Name	Product	Remarks and Limitations
`label2rgb`	Image Processing Toolbox	Referring to the standard syntax: `RGB = label2rgb(L, map, zerocolor, order)` • Submit at least two input arguments: the label matrix, `L`, and the colormap matrix, `map`. • `map` must be an `n-by-3`, `double`, colormap matrix. You cannot use a string containing the name of a MATLAB colormap function or a function handle of a colormap function. • If you set the boundary color `zerocolor` to the same color as one of the regions, `label2rgb` will not issue a warning. • If you supply a value for `order`, it must be `'noshuffle'`. MATLAB Function Block support: Yes.
`lcm`	MATLAB	—
`lcmvweights`	Phased Array System Toolbox	Does not support variable-size inputs.
`ldivide`	MATLAB	—
`le`	MATLAB	—
`le`	Fixed-Point Designer	• Not supported for fixed-point signals with different biases.
`length`	MATLAB	—
`length`	Fixed-Point Designer	—
`levinson`	Signal Processing Toolbox	• Code generation for this function requires the DSP System Toolbox software. • If specified, the order of recursion must be a constant. Expressions or variables are allowed if their values do not change.

Name	Product	Remarks and Limitations
limiter	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`lineToBorderPoints`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes

`linsolve`	MATLAB	• The option structure must be a constant.
		• Supports only a scalar option structure input. It does not support arrays of option structures.
		• Only optimizes these cases:
		  • `UT`
		  • `LT`
		  • `UHESS` = `true` (the `TRANSA` can be either `true` or `false`)
		  • `SYM` = `true` and `POSDEF` = `true`
		
		Other options are equivalent to using `mldivide`.

`linspace`	MATLAB	—

Name	Product	Remarks and Limitations
`load`	MATLAB	• Use only when generating MEX or code for Simulink simulation. To load compile-time constants, use `coder.load`. • Does not support use of the function without assignment to a structure or array. For example, use `S = load(filename)`, not `load(filename)`. • The output `S` must be the name of a structure or array without any subscripting. For example, `S(i) = load('myFile.mat')` is not allowed. • Arguments to `load` must be compile-time constant strings. • Does not support loading objects. • If the MAT-file contains unsupported constructs, use `load(filename,variables)` to load only the supported constructs. • You cannot use `save` in a function intended for code generation. The code generation software does not support the `save` function. Furthermore, you cannot use `coder.extrinsic` with `save`. Prior to generating code, you can use `save` to save the workspace data to a MAT-file. You must use `coder.varsize` to explicitly declare variable-size data loaded using the `load` function.
`local2globalcoord`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`log`	MATLAB	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`log2`	MATLAB	—
`log10`	MATLAB	—
`log1p`	MATLAB	—
`logical`	MATLAB	—
`logical`	Fixed-Point Designer	—
`logncdf`	Statistics and Machine Learning Toolbox	—
`logninv`	Statistics and Machine Learning Toolbox	—
`lognpdf`	Statistics and Machine Learning Toolbox	—
`lognrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`lognstat`	Statistics and Machine Learning Toolbox	—
`logspace`	MATLAB	—

Name	Product	Remarks and Limitations
`lower`	MATLAB	• Supports only `char` inputs. Does not support cell arrays. • Input values must be in the range 0-127.
`lowerbound`	Fixed-Point Designer	—
`lsb`	Fixed-Point Designer	• Supported for scalar fixed-point signals only. • Supported for scalar, vector, and matrix, `fi` single and double signals.
`lsqnonneg`	MATLAB	• You must enable support for variable-size arrays. • The `message` string in the output structure `output` (the fifth output) is not translated.
`lt`	MATLAB	—
`lteZadoffChuSeq`	Communications System Toolbox	—
`lt`	Fixed-Point Designer	• Not supported for fixed-point signals with different biases.
`lu`	MATLAB	—
`mad`	Statistics and Machine Learning Toolbox	Input `dim` cannot be empty.
`magic`	MATLAB	“Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30

Name	Product	Remarks and Limitations
`matchFeatures`	Computer Vision System Toolbox	Generates platform-dependent library: Yes for MATLAB host only when using the `Exhaustive` method. Generates portable C code for non-host target only when using the `Exhaustive` method. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries when not using the `Exhaustive` method. "Portable C Code Generation for Functions That Use OpenCV Library" Compile-time constant input: `'Method'` and `'Metric'`. Supports MATLAB Function block: No
`max`	MATLAB	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4..
`max`	Fixed-Point Designer	—
`maxflat`	Signal Processing Toolbox	Inputs must be constant. Expressions or variables are allowed if their values do not change.
`mdltest`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`mean`	MATLAB	• If specified, `dim` must be a constant. • The `outtype` and `nanflag` options must be constant strings. • Does not support the `'native'` output data type option for integer types. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`mean`	Fixed-Point Designer	N/A
`mean2`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`medfilt2`	Image Processing Toolbox	The `padopt` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The neighborhood size input argument must be a compile-time constant.
`median`	MATLAB	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`median`	Fixed-Point Designer	—
`meshgrid`	MATLAB	—
`mfilename`	MATLAB	—

Name	Product	Remarks and Limitations
`min`	MATLAB	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`min`	Fixed-Point Designer	—
`minus`	MATLAB	—
`minus`	Fixed-Point Designer	• Any non-`fi` input must be constant. Its value must be known at compile time so that it can be cast to a `fi` object.

Name	Product	Remarks and Limitations

`mkpp`	MATLAB	• The output structure `pp` differs from the `pp` structure in MATLAB. In MATLAB, `ppval` cannot use the `pp` structure from the code generation software. For code generation, `ppval` cannot use a `pp` structure created by MATLAB. `unmkpp` can use a MATLAB `pp` structure for code generation.
		
		To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
		
		  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
		  • In MATLAB, use `mkpp` to create the `pp` structure.
		• If you do not provide `d`, then `coefs` must be two-dimensional and have a fixed number of columns. In this case, the number of columns is the order.
		• To define a piecewise constant polynomial, `coefs` must be a column vector or `d` must have at least two elements.
		• If you provide `d` and `d` is `1`, `d` must be a constant. Otherwise, if the input to `ppval` is nonscalar, the shape of the output of `ppval` can differ from `ppval` in MATLAB.
		• If you provide `d`, it must have a fixed length. One of the following sets of statements must be true:
		
		1 Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
		
		`size(coefs,j) = d(j)`
		`size(coefs,m+1) = npieces`

Name	Product	Remarks and Limitations

		`size(coefs,m+2) = order`
		`j` = 1,2,...,m. The dimension `m+2` must be fixed length.
		2 Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
		`size(coefs,1) = prod(d)*npieces`
		`size(coefs,2) = order`
		The second dimension must be fixed length.
		• If you do not provide `d`, the following statements must be true:
		Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
		`size(coefs,1) = prod(d)*npieces`
		`size(coefs,2) = order`
		The second dimension must be fixed length.

`mldivide`	MATLAB	—
`mnpdf`	Statistics and Machine Learning Toolbox	—
`mod`	MATLAB	• Performs the arithmetic using the output class. Results might not match MATLAB due to differences in rounding errors. If one of the inputs has type `int64` or `uint64`, then both inputs must have the same type.
`mode`	MATLAB	• Does not support third output argument `C` (cell array). • If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Name	Product	Remarks and Limitations
`moment`	Statistics and Machine Learning Toolbox	If `order` is nonintegral and `X` is real, use `moment(complex(X), order)`.
`mpower`	MATLAB	If `A` is a 2-by-2 or larger matrix and `B` is `Inf` or `-Inf`, `mpower(A,B)` returns a matrix of NaNs.

`mpower`	Fixed-Point Designer	• The exponent input, *k*, must be constant; that is, its value must be known at compile time.
		• Variable-size inputs are supported only when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
		• For variable-size signals, you can see different results between MATLAB and the generated code.
		  • In generated code, the output for variable-size signals is computed using the `SumMode` property of the governing `fimath`.
		  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when both inputs are nonscalar. However, if either input is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

Name	Product	Remarks and Limitations
`mpy`	Fixed-Point Designer	• Code generation in MATLAB does not support the syntax `F.mpy(a,b)`. You must use the syntax `mpy(F,a,b)`. • When you provide complex inputs to the `mpy` function inside a `MATLAB Function` block, you must declare the input as complex before running the simulation. To do so, go to the **Ports and data manager** and set the **Complexity** parameter for all known complex inputs to `On`.
`mrdivide`	MATLAB	—
`mrdivide`	Fixed-Point Designer	—
MSERRegions	Computer Vision System Toolbox	Supports MATLAB Function block: Yes For code generation, you must specify both the `pixellist` cell array and the `length` of each array, as the second input. The object outputs, `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`. Generated code for this function uses a precompiled platform-specific shared library.
`mtimes`	MATLAB	• Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, `(Inf + 1i)*1i = (Inf*0 – 1*1) + (Inf*1 + 1*0)i = NaN + Infi`. • “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30

Name	Product	Remarks and Limitations

`mtimes`	Fixed-Point Designer	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object.
		• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
		• For variable-sized signals, you may see different results between MATLAB and the generated code.
		  • In generated code, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath`.
		  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when both inputs are nonscalar. However, if either input is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

multibandParametricEQ	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`multithresh`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be compile-time constant.
`mvdrweights`	Phased Array System Toolbox	Does not support variable-size inputs.
NaN or `nan`	MATLAB	• Dimensions must be real, nonnegative, integers.

Name	Product	Remarks and Limitations
`nancov`	Statistics and Machine Learning Toolbox	If the input is variable-size and is `[]` at run time, returns `[]` not `NaN`.
`nanmax`	Statistics and Machine Learning Toolbox	—
`nanmean`	Statistics and Machine Learning Toolbox	—
`nanmedian`	Statistics and Machine Learning Toolbox	—
`nanmin`	Statistics and Machine Learning Toolbox	—
`nanstd`	Statistics and Machine Learning Toolbox	—
`nansum`	Statistics and Machine Learning Toolbox	—
`nanvar`	Statistics and Machine Learning Toolbox	—
`nargin`	MATLAB	—
`narginchk`	MATLAB	—
`nargout`	MATLAB	• For a function with no output arguments, returns `1` if called without a terminating semicolon. **Note:** This behavior also affects extrinsic calls with no terminating semicolon. `nargout` is `1` for the called function in MATLAB.

Name	Product	Remarks and Limitations
`nargoutchk`	MATLAB	—
`nbincdf`	Statistics and Machine Learning Toolbox	—
`nbininv`	Statistics and Machine Learning Toolbox	—
`nbinpdf`	Statistics and Machine Learning Toolbox	—
`nbinrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`nbinstat`	Statistics and Machine Learning Toolbox	—
`ncfcdf`	Statistics and Machine Learning Toolbox	—
`ncfinv`	Statistics and Machine Learning Toolbox	—
`ncfpdf`	Statistics and Machine Learning Toolbox	—
`ncfrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.

Name	Product	Remarks and Limitations
`ncfstat`	Statistics and Machine Learning Toolbox	—
`nchoosek`	MATLAB	• When the first input, `x`, is a scalar, `nchoosek` returns a binomial coefficient. In this case, `x` must be a nonnegative integer. It cannot have type `int64` or `uint64`. • When the first input, `x`, is a vector, `nchoosek` treats it as a set. In this case, `x` can have type `int64` or `uint64`. • The second input, `k`, cannot have type `int64` or `uint64`. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`nctcdf`	Statistics and Machine Learning Toolbox	—
`nctinv`	Statistics and Machine Learning Toolbox	—
`nctpdf`	Statistics and Machine Learning Toolbox	—
`nctrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`nctstat`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`ncx2cdf`	Statistics and Machine Learning Toolbox	—
`ncx2rnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`ncx2stat`	Statistics and Machine Learning Toolbox	—
`ndgrid`	MATLAB	—
`ndims`	MATLAB	—
`ndims`	Fixed-Point Designer	—
`ne`	MATLAB	—
`ne`	Fixed-Point Designer	• Not supported for fixed-point signals with different biases.
`nearest`	Fixed-Point Designer	—
`nextpow2`	MATLAB	—
`nnz`	MATLAB	—
noiseGate	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`noisepow`	Phased Array System Toolbox	Does not support variable-size inputs.
`nonzeros`	MATLAB	—
`norm`	MATLAB	—

Name	Product	Remarks and Limitations
`normcdf`	Statistics and Machine Learning Toolbox	—
`normest`	MATLAB	—
`norminv`	Statistics and Machine Learning Toolbox	—
`normpdf`	Statistics and Machine Learning Toolbox	—
`normrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`normstat`	Statistics and Machine Learning Toolbox	—
`not`	MATLAB	—
`npwgnthresh`	Phased Array System Toolbox	Does not support variable-size inputs.
`nthroot`	MATLAB	—
`null`	MATLAB	• Might return a different basis than MATLAB • Does not support rational basis option (second input)
`num2hex`	MATLAB	—
`numberofelements`	Fixed-Point Designer	`numberofelements` will be removed in a future release. Use `numel` instead.
`numel`	MATLAB	—
`numel`	Fixed-Point Designer	—

Name	Product	Remarks and Limitations
`numerictype`	Fixed-Point Designer	• Fixed-point signals coming into a `MATLAB Function` block from Simulink are assigned a `numerictype` object that is populated with the signal's data type and scaling information. • Returns the data type when the input is a nonfixed-point signal. • Use to create `numerictype` objects in the generated code. • All `numerictype` object properties related to the data type must be constant.
`nuttallwin`	Signal Processing Toolbox	Inputs must be constant. Expressions or variables are allowed if their values do not change.
`ocr`	Computer Vision System Toolbox	Compile-time constant input: `TextLayout`, `Language`, and `CharacterSet`. Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
ocrText	Computer Vision System Toolbox	Supports MATLAB Function block: No
`ode23`	MATLAB	• All `odeset` option arguments must be constant. • Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function . • You must provide at least the two output arguments `T` and `Y`. • Input types must be homogeneous—all double or all single. • Variable-sizing support must be enabled. Requires dynamic memory allocation when `tspan` has two elements or you use event functions.

Name	Product	Remarks and Limitations
`ode45`	MATLAB	• All `odeset` option arguments must be constant. • Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function . • You must provide at least the two output arguments `T` and `Y`. • Input types must be homogeneous—all double or all single. • Variable-sizing support must be enabled. Requires dynamic memory allocation when `tspan` has two elements or you use event functions.
`odeget`	MATLAB	The `name` argument must be constant.
`odeset`	MATLAB	All inputs must be constant.
offsetstrel	Image Processing Toolbox	The `'ball'` input argument and all other input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`ones`	MATLAB	• Dimensions must be real, nonnegative integers. • The input `optimfun` must be a function supported for code generation.
opticalFlowFarneback	Computer Vision System Toolbox	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”

Name	Product	Remarks and Limitations
opticalFlowHS	Computer Vision System Toolbox	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
opticalFlowLK	Computer Vision System Toolbox	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
opticalFlowLKDoG	Computer Vision System Toolbox	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
`optimget`	MATLAB	Input parameter names must be constant.
`optimset`	MATLAB	• Does not support the syntax that has no input or output arguments: `optimset` • Functions specified in the options must be supported for code generation. • The fields of the options structure `oldopts` must be fixed-size fields. • For code generation, optimization functions ignore the `Display` option. • Does not support the additional options in an options structure created by the Optimization Toolbox `optimset` function. If an input options structure includes the additional Optimization Toolbox options, the output structure does not include them.
`ordfilt2`	Image Processing Toolbox	The `padopt` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`or`	MATLAB	—

Name	Product	Remarks and Limitations
`orth`	MATLAB	• Can return a different basis than MATLAB
`otsuthresh`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`padarray`	Image Processing Toolbox	Support only up to 3-D inputs. Input arguments, `padval` and `direction` are expected to be compile-time constants. MATLAB Function Block support: Yes. The input argument `padsize` must be a compile-time constant.
`parfor`	MATLAB	Treated as a `for`-loop in a `MATLAB Function` block.
`parzenwin`	Signal Processing Toolbox	Inputs must be constant. Expressions or variables are allowed if their values do not change.
`pascal`	MATLAB	—
`pca`	Statistics and Machine Learning Toolbox	• Ignores the `'Display'` value for `'Options'` when `'Algorithm'` is `'als'`. • If supplied, `'Weights'` and `'VariableWeights'` must be real. • Always returns the fifth output `explained` as a column vector. • Always returns the sixth output `mu` as a row vector. • If `mu` is empty, `pca` returns `mu` as a 1-by-0 array. `pca` does not convert `mu` to a 0-by-0 empty array. • Does not treat an input matrix `X` that has all NaN values as a special case. The outputs have the sizes that they have when some of the inputs are finite.

Name	Product	Remarks and Limitations

`pchip`	MATLAB	• Input `x` must be strictly increasing.
		• Does not remove `y` entries with `NaN` values.
		• If you generate code for the `pp = pchip(x,y)` syntax, you cannot input `pp` to the `ppval` function in MATLAB. To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
		  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
		  • In MATLAB, use `mkpp` to create the `pp` structure.

`pdf`	Statistics and Machine Learning Toolbox	—
`peak2peak`	Signal Processing Toolbox	—
`peak2rms`	Signal Processing Toolbox	—
`pearsrnd`	Statistics and Machine Learning Toolbox	Matches MATLAB only when generated output `r` is scalar.
`permute`	MATLAB	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`permute`	Fixed-Point Designer	The dimensions argument must be a built-in type; it cannot be a `fi` object.
phased.ADPCACanceller	Phased Array System Toolbox	"System Objects in MATLAB Code Generation"
phased.AngleDoppler-Response	Phased Array System Toolbox	"System Objects in MATLAB Code Generation"

Name	Product	Remarks and Limitations
phased.ArrayGain	Phased Array System Toolbox	• Does not support arrays containing polarized antenna elements, that is, the `phased.ShortDipoleAntennaElement` or `phased.CrossedDipoleAntennaElement` antennas. • "System Objects in MATLAB Code Generation"
phased.ArrayResponse	Phased Array System Toolbox	"System Objects in MATLAB Code Generation"

Name	Product	Remarks and Limitations
`planerot`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`plus`	MATLAB	—
`plus`	Fixed-Point Designer	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object.
`poisscdf`	Statistics and Machine Learning Toolbox	—
`poissinv`	Statistics and Machine Learning Toolbox	—
`poisspdf`	Statistics and Machine Learning Toolbox	—
`poissrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`poisstat`	Statistics and Machine Learning Toolbox	—
`pol2cart`	MATLAB	—
`pol2circpol`	Phased Array System Toolbox	Does not support variable-size inputs.
`polellip`	Phased Array System Toolbox	Does not support variable-size inputs.
`polloss`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`polratio`	Phased Array System Toolbox	Does not support variable-size inputs.
`polsignature`	Phased Array System Toolbox	• Does not support variable-size inputs. • Supported only when output arguments are specified.
`poly`	MATLAB	• Does not discard nonfinite input values • Complex input produces complex output • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`polyarea`	MATLAB	—
`poly2trellis`	Communications System Toolbox	—
`polyder`	MATLAB	The output can contain fewer `NaN`s than the MATLAB output. However, if the input contains a `NaN`, the output contains at least one `NaN`.
`polyfit`	MATLAB	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`polyint`	MATLAB	—
`polyval`	MATLAB	—
`polyvalm`	MATLAB	—
`pow2`	Fixed-Point Designer	—
`pow2db`	Signal Processing Toolbox	—

Name	Product	Remarks and Limitations
`power`	MATLAB	• Generates an error during simulation. When both `X` and `Y` are real, but `power(X,Y)` is complex, returns `NaN` in the generated code. To get the complex result, make the input value `X` complex by passing in `complex(X)`. For example, `power(complex(X),Y)`. • Generates an error during simulation. When both `X` and `Y` are real, but `X .^ Y` is complex, returns `NaN` in generated code. To get the complex result, make the input value `X` complex by using `complex(X)`. For example, `complex(X).^Y`.
`power`	Fixed-Point Designer	• The exponent input, `k`, must be constant. Its value must be known at compile time.
`ppval`	MATLAB	The size of output `v` does not match MATLAB when both of the following statements are true: • The input `x` is a variable-size array that is not a variable-length vector. • `x` becomes a row vector at run time. The code generation software does not remove the singleton dimensions. However, MATLAB might remove singleton dimensions. For example, suppose that `x` is a :4-by-:5 array (the first dimension is variable size with an upper bound of 4 and the second dimension is variable size with an upper bound of 5). Suppose that `ppval(pp,0)` returns a 2-by-3 fixed-size array. `v` has size 2-by-3-by-:4-by-:5. At run time, suppose that, size(x,1) =1 and size (x,2) = 5. In the generated code, the size(v) is [2,3,1,5]. In MATLAB, the size is [2,3,5].

Name	Product	Remarks and Limitations

`prctile`	Statistics and Machine Learning Toolbox	• "Automatic dimension restriction"
		• If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
		  • You do not supply the `dim` input.
		  • `X` is a variable-size array.
		  • `X` is not a variable-length vector.
		  • `X` is a vector at run time.
		  • The orientation of the vector `X` does not match the orientation of the vector `p`.
		  In this case, the output `Y` matches the orientation of `X` not the orientation of `p`.

`primes`	MATLAB	• The maximum double precision input is `2^32`. • The maximum single precision input is `2^24`. • The input `n` cannot have type `int64` or `uint64`.
`prod`	MATLAB	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
projective2d	Image Processing Toolbox	When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`psi`	MATLAB	—
`psnr`	Image Processing Toolbox	MATLAB Function Block support: Yes.
`pulsint`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`qamdemod`	Communications System Toolbox	—
`qammod`	Communications System Toolbox	—
`qr`	MATLAB	—
`quad2d`	MATLAB	• Generates a warning if the size of the internal storage arrays is not large enough. If a warning occurs, a possible workaround is to divide the region of integration into pieces and sum the integrals over each piece.
`quadgk`	MATLAB	—
`quantile`	Statistics and Machine Learning Toolbox	—
`quantize`	Fixed-Point Designer	—
`quat2axang`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`quat2eul`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`quat2rotm`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`quat2tform`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`quatconj`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset™ software.
`quatdivide`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.
`quatinv`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.
`quatmod`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.

Name	Product	Remarks and Limitations
`quatmultiply`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.
`quatnorm`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.
`quatnormalize`	Aerospace Toolbox	Code generation for this function requires the Aerospace Blockset software.
`rad2deg`	MATLAB	—
`radareqpow`	Phased Array System Toolbox	Does not support variable-size inputs.
`radareqrng`	Phased Array System Toolbox	Does not support variable-size inputs.
`radareqsnr`	Phased Array System Toolbox	Does not support variable-size inputs.
`radarvcd`	Phased Array System Toolbox	Does not support variable-size inputs.
`radialspeed`	Phased Array System Toolbox	Does not support variable-size inputs.
`rainpl`	Phased Array System Toolbox	Does not support variable-size inputs.
`rand`	MATLAB	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `rand` method for other classes. For example, `rand(sz,'myclass')` does not invoke `myclass.rand(sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`randg`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`randi`	MATLAB	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `randi` method for other classes. For example, `randi(imax,sz,'myclass')` does not invoke `myclass.randi(imax,sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`randn`	MATLAB	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `randn` method for other classes. For example, `randn(sz,'myclass')` does not invoke `myclass.randn(sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`random`	Statistics and Machine Learning Toolbox	—
`randperm`	MATLAB	—
`randsample`	Statistics and Machine Learning Toolbox	When sampling without replacement, the order of the output values might not match MATLAB.
`range`	Fixed-Point Designer	—
`range2beat`	Phased Array System Toolbox	Does not support variable-size inputs.
`range2bw`	Phased Array System Toolbox	Does not support variable-size inputs.
`range2time`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`rangeangle`	Phased Array System Toolbox	Does not support variable-size inputs.
`rank`	MATLAB	—
`raylcdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`recursiveARX`	System Identification Toolbox	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveBJ`	System Identification Toolbox	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveLS`	System Identification Toolbox	• For Simulink-based workflows, use `Recursive Least Squares Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveOE`	System Identification Toolbox	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`rectwin`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`regionprops`	Image Processing Toolbox	Supports only 2-D images. Does not support the table output type. Does not accept cell arrays as input—use a comma-separated list instead. Does not support the properties `ConvexArea`, `ConvexHull`, `ConvexImage`, `Solidity`, and `SubarrayIdx`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.

Name	Product	Remarks and Limitations
`reinterpretcast`	Fixed-Point Designer	—
`rem`	MATLAB	• Performs the arithmetic using the output class. Results might not match MATLAB due to differences in rounding errors. • If one of the inputs has type `int64` or `uint64`, then both inputs must have the same type.
`removefimath`	Fixed-Point Designer	—
`repmat`	MATLAB	Size arguments must have a fixed size.
`repmat`	Fixed-Point Designer	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`resample`	Signal Processing Toolbox	• C and C++ code generation for `resample` requires DSP System Toolbox software. • The upsampling and downsampling factors must be specified as constants. Expressions or variables are allowed if their values do not change.
`rescale`	Fixed-Point Designer	—
`reshape`	MATLAB	• If the input is a compile-time empty cell array, then the size arguments must be constants. • Size arguments must have a fixed size. • “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30
`reshape`	Fixed-Point Designer	—
`return`	MATLAB	—

Name	Product	Remarks and Limitations
reverberator	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
`rgb2gray`	MATLAB	MATLAB Function Block support: Yes.
`rgb2lab`	Image Processing Toolbox	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`rgb2ycbcr`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`rms`	Signal Processing Toolbox	—

`rng`	MATLAB	• Supports only the `'twister'`, `'v5normal'`, and `'v4'` generators.
		• Does not support the `'shuffle'` input.
		• For a MEX target:
		  • If extrinsic calls are disabled or `rng` is called inside a `parfor` loop, the output of `rng` in the MEX function is not compatible with the `rng` function in MATLAB. You cannot pass the output of `s = rng` from the MEX function to `rng` in MATLAB.
		  • If extrinsic calls are enabled and `rng` is not called from inside a `parfor` loop, only `rng` can access the data in the structure that `rng` returns.

robotics.ParticleFilter	Robotics System Toolbox	Supports MATLAB Function block: No
robotics.PurePursuit	Robotics System Toolbox	Supports MATLAB Function block: No

Name	Product	Remarks and Limitations
robotics.VectorFieldHistogram	Robotics System Toolbox	Supports MATLAB Function block: No
`rocpfa`	Phased Array System Toolbox	• Does not support variable-size inputs. • The `NonfluctuatingNoncoherent` signal type is not supported.
`rocsnr`	Phased Array System Toolbox	• Does not support variable-size inputs. • Does not support the `NonfluctuatingNoncoherent` signal type.
`rootmusicdoa`	Phased Array System Toolbox	Does not support variable-size inputs.
`roots`	MATLAB	• Output is variable size. • Output is complex. • Roots are not always in the same order as MATLAB. • Roots of poorly conditioned polynomials do not always match MATLAB. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`rosser`	MATLAB	—
`rot90`	MATLAB	Does not support cell arrays for the first argument.
`rot90`	Fixed-Point Designer	In the syntax `rot90(A,k)`, the argument `k` must be a built-in type; it cannot be a `fi` object.
`rotationMatrixToVector`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
`rotationVectorToMatrix`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
`rotm2axang`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`rotm2eul`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes

Name	Product	Remarks and Limitations
`rotm2quat`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`rotm2tform`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`rotx`	Phased Array System Toolbox	Does not support variable-size inputs.
`roty`	Phased Array System Toolbox	Does not support variable-size inputs.
`rotz`	Phased Array System Toolbox	Does not support variable-size inputs.
`round`	MATLAB	Supports only the syntax `Y = round(X)`.
`round`	Fixed-Point Designer	—
`rsf2csf`	MATLAB	—
`schur`	MATLAB	Can return a different Schur decomposition in generated code than in MATLAB.
`sec`	MATLAB	—
`secd`	MATLAB	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`sech`	MATLAB	—
`selectStrongestBbox`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`sensorcov`	Phased Array System Toolbox	Does not support variable-size inputs.
`sensorsig`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations

`setdiff`	MATLAB	• Does not support cell arrays for the first or second arguments.
		• When you do not specify the `'rows'` option:
		  • Inputs `A` and `B` must be vectors. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
		  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
		  • Do not use `[]` to represent the empty set. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
		  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
		• When you specify both the `'legacy'` and `'rows'` options, the output `ia` is a column vector. If `ia` is empty, it is 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
		• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
		• Complex inputs must be `single` or `double`.
		• When one input is complex and the other input is real, do one of the following:
		  • Set `setOrder` to `'stable'`.
		  • Sort the real input in complex ascending order (by absolute value). Suppose the real input

Name	Product	Remarks and Limitations
		is `x`. Use `sort(complex(x))` or `sortrows(complex(x))`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`setfimath`	Fixed-Point Designer	—

Name	Product	Remarks and Limitations

`setxor`	MATLAB	• Does not support cell arrays for the first or second arguments.
		• When you do not specify the `'rows'` option:
		  • Inputs `A` and `B` must be vectors with the same orientation. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
		  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
		  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example , `zeros(1,0)`, to represent the empty set.
		  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
		• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
		• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` flag, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
		• Complex inputs must be `single` or `double`.
		• When one input is complex and the other input is real, do one of the following:
		  • Set `setOrder` to `'stable'`.
		  • Sort the real input in complex ascending order (by absolute

Name	Product	Remarks and Limitations
		value). Suppose the real input is `x`. Use `sort(complex(x))` or `sortrows(complex(x))`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`sfi`	Fixed-Point Designer	• All properties related to data type must be constant for code generation.
`sgolay`	Signal Processing Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`shiftdim`	MATLAB	• Does not support cell arrays for the first argument. • Second argument must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`shiftdim`	Fixed-Point Designer	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`shnidman`	Phased Array System Toolbox	Does not support variable-size inputs.
`sign`	MATLAB	—
`sign`	Fixed-Point Designer	—
`sin`	MATLAB	—
`sin`	Fixed-Point Designer	—
`sind`	MATLAB	—
`single`	MATLAB	—
`single`	Fixed-Point Designer	—
`sinh`	MATLAB	—

Name	Product	Remarks and Limitations
`size`	MATLAB	—
`size`	Fixed-Point Designer	—
`skewness`	Statistics and Machine Learning Toolbox	—
`sort`	MATLAB	• Does not support cell arrays for the first argument. • If the input is a complex type, `sort` orders the output according to absolute value. When `x` is a complex type that has all zero imaginary parts, use `sort(real(x))` to compute the sort order for real types. See "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`sort`	Fixed-Point Designer	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`sortrows`	MATLAB	• Does not support cell arrays for the first argument. • If the input is a complex type, `sortrows` orders the output according to absolute value. When `x` is a complex type that has all zero imaginary parts, use `sortrows(real(x))` to compute the sort order for real types. See "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`sosfilt`	Signal Processing Toolbox	—
`speed2dop`	Phased Array System Toolbox	Does not support variable-size inputs.
`sph2cart`	MATLAB	—

Name	Product	Remarks and Limitations
`sph2cartvec`	Phased Array System Toolbox	Does not support variable-size inputs.

`spline`	MATLAB	• Input `x` must be strictly increasing.
		• Does not remove `Y` entries with `NaN` values.
		• Does not report an error for infinite endslopes in `Y`.
		• If you generate code for the `pp = spline(x,Y)` syntax, you cannot input `pp` to the `ppval` function in MATLAB. To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
		  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
		  • In MATLAB, use `mkpp` to create the `pp` structure.

`spsmooth`	Phased Array System Toolbox	Does not support variable-size inputs.
`squeeze`	MATLAB	Does not support cell arrays.
`squeeze`	Fixed-Point Designer	—
`sqrt`	MATLAB	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`sqrt`	Fixed-Point Designer	• Complex and [Slope Bias] inputs error out. • Negative inputs yield a 0 result.
`sqrtm`	MATLAB	—

Name	Product	Remarks and Limitations
`std`	MATLAB	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`steervec`	Phased Array System Toolbox	Does not support variable-size inputs.
`stereoAnaglyph`	Computer Vision System Toolbox	Supports MATLAB Function block: Yes
stereoParameters	Computer Vision System Toolbox	Supports MATLAB Function block: No Use the toStruct method to pass a `stereoParameters` object into generated code. See the "Code Generation for Depth Estimation From Stereo Video" example.
`stokes`	Phased Array System Toolbox	• Does not support variable-size inputs. • Supported only when output arguments are specified.
`storedInteger`	Fixed-Point Designer	—
`storedIntegerToDouble`	Fixed-Point Designer	—
`str2double`	MATLAB	• Does not support cell arrays. • Always returns a complex result.
`str2func`	MATLAB	String must be constant/known at compile time.
`strcmp`	MATLAB	• Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.

Name	Product	Remarks and Limitations
`strcmpi`	MATLAB	• Does not support enumeration inputs. • Input values from the `char` class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.
strel	Image Processing Toolbox	All of the input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`stretchfreq2rng`	Phased Array System Toolbox	Does not support variable-size inputs.
`stretchlim`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`strfind`	MATLAB	• Does not support cell arrays. • If `pattern` does not exist in `str`, returns `zeros(1,0)` not `[]`. To check for an empty return, use `isempty`. • Inputs must be character row vectors.
`strjoin`	MATLAB	Always returns a string that has size 1-by-n. For empty inputs, returns a 1-by-0 string not `[]`.
`strjust`	MATLAB	Does not support a cell array of strings for the first argument.

Name	Product	Remarks and Limitations
`strncmp`	MATLAB	• Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.
`strncmpi`	MATLAB	• Does not support enumeration inputs. • Input values from the `char` class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.
`strrep`	MATLAB	• Does not support cell arrays. • If `oldSubstr` does not exist in `origStr`, returns `blanks(0)`. To check for an empty return, use `isempty`. • Inputs must be character row vectors.
`strtok`	MATLAB	Does not support cell arrays for the first argument.
`strtrim`	MATLAB	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.
`struct`	MATLAB	• You cannot create a structure that contains a cell array. For example, you cannot generate code for: `s = struct('a',{{1 2}})` • If the `value` argument is a cell array, all elements must have the same type.

Name	Product	Remarks and Limitations
`struct2cell`	MATLAB	• For a variable-size structure array, the resulting cell array must be homogeneous. If `s` is a variable-size structure array, the fields must have the same type. • If `struct2cell` cannot convert `s` to a homogeneous cell array, the output cell array is heterogeneous. A heterogeneous output cell array can have a maximum of 1024 elements.
`structfun`	MATLAB	• Does not support the `ErrorHandler` option. • The number of outputs must be less than or equal to three.
`sub`	Fixed-Point Designer	Code generation in MATLAB does not support the syntax `F.sub(a,b)`. You must use the syntax `sub(F,a,b)`.
`sub2ind`	MATLAB	• The first argument must be a valid size vector. Size vectors for arrays with more than `intmax` elements are not supported. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`subsasgn`	Fixed-Point Designer	—
`subspace`	MATLAB	—
`subsref`	Fixed-Point Designer	—
`sum`	MATLAB	• If specified, `dim` must be a constant. • The `outtype` and `nanflag` options must be constant strings. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Name	Product	Remarks and Limitations
`sum`	Fixed-Point Designer	• Variable-size inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
`superpixels`	Image Processing Toolbox	String input arguments must be compile-time constants. The value of `'IsInputLab'` (true or false) must be a compile-time constant. MATLAB Function Block support: No.
`surfacegamma`	Phased Array System Toolbox	Does not support variable-size inputs.
`surfclutterrcs`	Phased Array System Toolbox	Does not support variable-size inputs.
SURFPoints	Computer Vision System Toolbox	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.
`svd`	MATLAB	Uses a different `SVD` implementation than MATLAB. Because the singular value decomposition is not unique, left and right singular vectors might differ from those computed by MATLAB.
`swapbytes`	MATLAB	Inheritance of the class of the input to `swapbytes` in a `MATLAB Function` block is supported only when the class of the input is `double`. For non-double inputs, the input port data types must be specified, not inherited.

Name	Product	Remarks and Limitations
`switch, case, otherwise`	MATLAB	• If all case expressions are scalar integer values, generates a C `switch` statement. At run time, if the switch value is not an integer, generates an error. • When the case expressions contain noninteger or nonscalar values, the code generation software generates C `if` statements in place of a C `switch` statement.
`systemp`	Phased Array System Toolbox	Does not support variable-size inputs.
`tan`	MATLAB	—
`tand`	MATLAB	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`tanh`	MATLAB	—
`taylorwin`	Signal Processing Toolbox	Inputs must be constant
`tcdf`	Statistics and Machine Learning Toolbox	—
`tf2ca`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`tf2cl`	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`tform2axang`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`tform2eul`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`tform2quat`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes

Name	Product	Remarks and Limitations
`tform2rotm`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`tform2trvec`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`time2range`	Phased Array System Toolbox	Does not support variable-size inputs.
`times`	MATLAB	Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, `(Inf + 1i)*1i = (Inf*0 – 1*1) + (Inf*1 + 1*0)i = NaN + Infi`.
`times`	Fixed-Point Designer	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object. • When you provide complex inputs to the `times` function inside a `MATLAB Function` block, you must declare the input as complex before running the simulation. To do so, go to the **Ports and data manager** and set the **Complexity** parameter for all known complex inputs to `On`.
`tinv`	Statistics and Machine Learning Toolbox	—
`toeplitz`	MATLAB	—
`tpdf`	Statistics and Machine Learning Toolbox	—
`trace`	MATLAB	—
`transpose`	MATLAB	—

Name	Product	Remarks and Limitations
`transpose`	Fixed-Point Designer	—
`trapz`	MATLAB	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`triang`	Signal Processing Toolbox	Inputs must be constant
`triangulate`	Computer Vision System Toolbox	Supports MATLAB Function block: No
`tril`	MATLAB	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
`tril`	Fixed-Point Designer	• If supplied, the index, *k*, must be a real and scalar integer value that is not a `fi` object.
`triu`	MATLAB	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
`triu`	Fixed-Point Designer	• If supplied, the index, *k*, must be a real and scalar integer value that is not a `fi` object.
`trnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`true`	MATLAB	• Dimensions must be real, nonnegative, integers.
`trvec2tform`	Robotics System Toolbox	Supports `MATLAB Function` block: Yes
`tstat`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`tukeywin`	Signal Processing Toolbox	Inputs must be constant.
`typecast`	MATLAB	• Value of string input argument `type` must be lowercase. • When you use `typecast` with inheritance of input port data types in `MATLAB Function` blocks, you can receive a size error. To avoid this error, specify the block input port data types explicitly. • Integer input or result classes must map directly to a C type on the target hardware. • The input must be a variable-length vector or a fixed-size vector. See "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • The output vector always has the same orientation as the input vector.
`ufi`	Fixed-Point Designer	• All properties related to data type must be constant for code generation.
`uint8`, `uint16`, `uint32`, `uint64`	MATLAB	—
`uint8`, `uint16`, `uint32`, `uint64`	Fixed-Point Designer	—
`uminus`	MATLAB	—
`uminus`	Fixed-Point Designer	—
`undistortImage`	Computer Vision System Toolbox	Compile-time constant input restriction: `'interp'` and `'OutputView'` Supports MATLAB Function block: No
`unidcdf`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`unidinv`	Statistics and Machine Learning Toolbox	—
`unidpdf`	Statistics and Machine Learning Toolbox	—
`unidrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`unidstat`	Statistics and Machine Learning Toolbox	—
`unifcdf`	Statistics and Machine Learning Toolbox	—
`unifinv`	Statistics and Machine Learning Toolbox	—
`unifpdf`	Statistics and Machine Learning Toolbox	—
`unifrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`unifstat`	Statistics and Machine Learning Toolbox	—

Name	Product	Remarks and Limitations
`unigrid`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations

`union`	MATLAB	• Does not support cell arrays for the first or second arguments.
		• When you do not specify the `'rows'` option:
		  • Inputs `A` and `B` must be vectors with the same orientation. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
		  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
		  • The input`[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example , `zeros(1,0)`, to represent the empty set.
		  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
		• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
		• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
		• Complex inputs must be `single` or `double`.
		• When one input is complex and the other input is real, do one of the following:
		  • Set `setOrder` to `'stable'`.
		  • Sort the real input in complex ascending order (by absolute

Name	Product	Remarks and Limitations
		value). Suppose the real input is `x`. Use `sort(complex(x))` or `sortrows(complex(x))`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

`unique`	MATLAB	• Does not support cell arrays for the first argument.
		• When you do not specify the `'rows'` option:
		  • The input `A` must be a vector. If you specify the `'legacy'` option, the input `A` must be a row vector.
		  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
		  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
		  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
		• When you specify both the `'rows'` option and the `'legacy'` option, outputs `ia` and `ic` are column vectors. If these outputs are empty, they are 0-by-1, even if the output `C` is 0-by-0.
		• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the input `A` must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
		• Complex inputs must be `single` or `double`.

Name	Product	Remarks and Limitations
`unmkpp`	MATLAB	• `pp` must be a valid piecewise polynomial structure created by `mkpp`, `spline`, or `pchip` in MATLAB or by the code generation software. • Does not support `pp` structures created by `interp1` in MATLAB.
`unwrap`	MATLAB	• Row vector input is only supported when the first two inputs are vectors and nonscalar • Performs arithmetic in the output class. Hence, results might not match MATLAB due to different rounding errors
`upfirdn`	Signal Processing Toolbox	• Code generation for this function requires the DSP System Toolbox software. • Filter coefficients, upsampling factor, and downsampling factor must be constants. Expressions or variables are allowed if their values do not change.
`uplus`	MATLAB	—
`uplus`	Fixed-Point Designer	—
`upper`	MATLAB	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.
`upperbound`	Fixed-Point Designer	—
`upsample`	Signal Processing Toolbox	Either declare input `n` as constant, or use the `assert` function in the calling function to set upper bounds for `n`. For example, `assert(n<10)`
`uv2azel`	Phased Array System Toolbox	Does not support variable-size inputs.

Name	Product	Remarks and Limitations
`uv2azelpat`	Phased Array System Toolbox	Does not support variable-size inputs.
`uv2phitheta`	Phased Array System Toolbox	Does not support variable-size inputs.
`uv2phithetapat`	Phased Array System Toolbox	Does not support variable-size inputs.
`val2ind`	Phased Array System Toolbox	Does not support variable-size inputs.
`vander`	MATLAB	—
`var`	MATLAB	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`vertcat`	Fixed-Point Designer	—
vision.AlphaBlender	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Autocorrelator	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.BlobAnalysis	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"

vision.MedianFilter	Computer Vision System Toolbox	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.Mean	Computer Vision System Toolbox	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.Minimum	Computer Vision System Toolbox	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.PeopleDetector	Computer Vision System Toolbox	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”
vision.PointTracker	Computer Vision System Toolbox	Supports MATLAB Function block: No Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”“System Objects in MATLAB Code Generation”
vision.Pyramid	Computer Vision System Toolbox	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”

Name	Product	Remarks and Limitations
vision.ShapeInserter	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.StandardDeviation	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.TemplateMatcher	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Variance	Computer Vision System Toolbox	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.VideoFileReader	Computer Vision System Toolbox	Supports MATLAB Function block: Yes Generated code for this function uses a precompiled platform-specific shared library. "System Objects in MATLAB Code Generation" Does not generate code for reading compressed images on the Mac.
vision.VideoFileWriter	Computer Vision System Toolbox	Supports MATLAB Function block: Yes Generated code for this function uses a precompiled platform-specific shared library. "System Objects in MATLAB Code Generation"
`vitdec`	Communications System Toolbox	—
`watershed`	Image Processing Toolbox	Supports only 2-D images. Supports only 4- or 8-connectivity. Supports only up to 65,535 regions. The output type is always `uint16`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
wavetableSynthesizer	Audio System Toolbox	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes

Name	Product	Remarks and Limitations
`wblcdf`	Statistics and Machine Learning Toolbox	—
`wblinv`	Statistics and Machine Learning Toolbox	—
`wblpdf`	Statistics and Machine Learning Toolbox	—
`wblrnd`	Statistics and Machine Learning Toolbox	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`wblstat`	Statistics and Machine Learning Toolbox	—
`while`	MATLAB	—
`wilkinson`	MATLAB	`n` must be a fixed-size scalar.
`wlanCoarseCFOEstimate`	WLAN System Toolbox™	—
`wlanFieldIndices`	WLAN System Toolbox	—
`wlanFineCFOEstimate`	WLAN System Toolbox	—
`wlanGeneratorConfig`	WLAN System Toolbox	—
`wlanHTConfig`	WLAN System Toolbox	—
`wlanHTData`	WLAN System Toolbox	Cannot be used in `MATLAB Function` block.

Name	Product	Remarks and Limitations
`wlanHTDataRecover`	WLAN System Toolbox	—
`wlanHTLTFChannel-Estimate`	WLAN System Toolbox	—
`wlanHTLTFDemodulate`	WLAN System Toolbox	—
`wlanHTLTF`	WLAN System Toolbox	—
`wlanHTSIG`	WLAN System Toolbox	—
`wlanHTSIGRecover`	WLAN System Toolbox	—
`wlanHTSTF`	WLAN System Toolbox	—
`wlanLLTF`	WLAN System Toolbox	—
`wlanLLTFChannelEstimate`	WLAN System Toolbox	—
`wlanLLTFDemodulate`	WLAN System Toolbox	—
`wlanLSIG`	WLAN System Toolbox	—
`wlanLSIGRecover`	WLAN System Toolbox	—
`wlanLSTF`	WLAN System Toolbox	—
`wlanNonHTConfig`	WLAN System Toolbox	—
`wlanNonHTData`	WLAN System Toolbox	Cannot be used in `MATLAB Function` block.
`wlanRecoveryConfig`	WLAN System Toolbox	—

Name	Product	Remarks and Limitations
wlanTGacChannel	WLAN System Toolbox	"System Objects in MATLAB Code Generation"
wlanTGnChannel	WLAN System Toolbox	"System Objects in MATLAB Code Generation"
`wlanVHTConfig`	WLAN System Toolbox	—
`wlanVHTData`	WLAN System Toolbox	Cannot be used in `MATLAB Function` block.
`wlanVHTDataRecover`	WLAN System Toolbox	Cannot be used in MATLAB Function block
`wlanVHTLTF`	WLAN System Toolbox	—
`wlanVHTLTFChannel-Estimate`	WLAN System Toolbox	—
`wlanVHTLTFDemodulate`	WLAN System Toolbox	—
`wlanVHTSIGA`	WLAN System Toolbox	—
`wlanVHTSIGARecover`	WLAN System Toolbox	—
`wlanVHTSIGBRecover`	WLAN System Toolbox	—
`wlanVHTSIGB`	WLAN System Toolbox	—
`wlanVHTSTF`	WLAN System Toolbox	—
`wlanWaveformGenerator`	WLAN System Toolbox	Cannot be used in `MATLAB Function` block.
`xcorr`	Signal Processing Toolbox	Leading ones in `size(x)` must be constant for every input `x`. If `x` is variable-size and is a row vector, it must be 1-by-`:`. It cannot be `:`-by-`:` with `size(x,1)` = 1 at run time.

Name	Product	Remarks and Limitations
`xor`	MATLAB	—
`ycbcr2rgb`	Image Processing Toolbox	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`yulewalk`	Signal Processing Toolbox	If specified, the order of recursion must be a constant. Expressions or variables are allowed if their values do not change.
`zeros`	MATLAB	• Dimensions must be real, nonnegative, integers.
`zp2tf`	MATLAB	—
`zscore`	Statistics and Machine Learning Toolbox	—

Functions and Objects Supported for C and C++ Code Generation — Category List

You can generate efficient C and C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These functions, classes, and System objects are listed by MATLAB category or toolbox category in the following tables.

For an alphabetical list of supported functions, classes, and System objects, see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2.

Note: For more information on code generation for fixed-point algorithms, refer to "Code Acceleration and Code Generation from MATLAB".

Aerospace Toolbox

C and C++ code generation for the following Aerospace Toolbox quaternion functions requires the Aerospace Blockset software.

Function	Remarks and Limitations
`quatconj`	—
`quatdivide`	—
`quatinv`	—
`quatmod`	—
`quatmultiply`	—
`quatnorm`	—
`quatnormalize`	—

Arithmetic Operations in MATLAB

See “Array vs. Matrix Operations” for detailed descriptions of the following operator equivalent functions.

Function	Remarks and Limitations
`ctranspose`	—
`idivide`	• For efficient generated code, MATLAB rules for divide by zero are supported only for the `'round'` option.
`isa`	—
`ldivide`	—
`minus`	—
`mldivide`	—

Function	Remarks and Limitations
`mpower`	If `A` is a 2-by-2 or larger matrix and `B` is `Inf` or `-Inf`, `mpower(A,B)` returns a matrix of NaNs.
`mrdivide`	—
`mtimes`	• Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, `(Inf + 1i)*1i = (Inf*0 – 1*1) + (Inf*1 + 1*0)i = NaN + Infi`. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`plus`	—
`power`	• Generates an error during simulation. When both `X` and `Y` are real, but `power(X,Y)` is complex, returns `NaN` in the generated code. To get the complex result, make the input value `X` complex by passing in `complex(X)`. For example, `power(complex(X),Y)`. • Generates an error during simulation. When both `X` and `Y` are real, but `X .^ Y` is complex, returns `NaN` in generated code. To get the complex result, make the input value `X` complex by using `complex(X)`. For example, `complex(X).^Y`.
`rdivide`	—
`times`	Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, `(Inf + 1i)*1i = (Inf*0 – 1*1) + (Inf*1 + 1*0)i = NaN + Infi`.
`transpose`	—
`uminus`	—
`uplus`	—

Audio System Toolbox

C and C++ code generation for the following functions and System objects requires the Audio System Toolbox software.

Name	Remarks and Limitations
Audio I/O and Waveform Generation	
audioDeviceReader	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
audioDeviceWriter	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
wavetableSynthesizer	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
audioOscillator	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
Audio Processing Algorithm Design	
`designVarSlopeFilter`	Supports MATLAB Function Block: Yes
`designParamEQ`	Supports MATLAB Function Block: Yes
`designShelvingEQ`	Supports MATLAB Function Block: Yes
crossoverFilter	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
compressor	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
expander	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
noiseGate	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
limiter	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes

Name	Remarks and Limitations
multibandParametricEQ	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
reverberator	"System Objects in MATLAB Code Generation" Supports MATLAB Function Block: Yes
Audio Plugins	
`audioPluginInterface`	Supports MATLAB Function Block: Yes
`audioPluginParameter`	Supports MATLAB Function Block: Yes
audioPlugin	Supports MATLAB Function Block: Yes
audioPluginSource	Supports MATLAB Function Block: Yes

Bit-Wise Operations MATLAB

Function	Remarks and Limitations
`flintmax`	—
`swapbytes`	Inheritance of the class of the input to `swapbytes` in a `MATLAB Function` block is supported only when the class of the input is `double`. For non-double inputs, the input port data types must be specified, not inherited.

Casting in MATLAB

Function	Remarks and Limitations
`cast`	—
`char`	Does not support cell arrays.
`class`	—
`double`	—
`int8`, `int16`, `int32`, `int64`	—
`logical`	—
`single`	—

Function	Remarks and Limitations
`typecast`	• Value of string input argument `type` must be lowercase. • When you use `typecast` with inheritance of input port data types in `MATLAB Function` blocks, you can receive a size error. To avoid this error, specify the block input port data types explicitly. • Integer input or result classes must map directly to a C type on the target hardware. • The input must be a variable-length vector or a fixed-size vector. See "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • The output vector always has the same orientation as the input vector.
`uint8`, `uint16`, `uint32`, `uint64`	—

Communications System Toolbox

C and C++ code generation for the following functions and System objects requires the Communications System Toolbox software.

Name	Remarks and Limitations
Input and Output	
comm.BarkerCode	"System Objects in MATLAB Code Generation"
comm.GoldSequence	"System Objects in MATLAB Code Generation"
comm.HadamardCode	"System Objects in MATLAB Code Generation"
comm.KasamiSequence	"System Objects in MATLAB Code Generation"

Complex Numbers in MATLAB

Function	Remarks and Limitations
`complex`	—
`conj`	—
`imag`	—
`isnumeric`	—
`isreal`	—
`isscalar`	—
`real`	—
`unwrap`	• Row vector input is only supported when the first two inputs are vectors and nonscalar • Performs arithmetic in the output class. Hence, results might not match MATLAB due to different rounding errors

Computer Vision System Toolbox

C and C++ code generation for the following functions and System objects requires the Computer Vision System Toolbox software.

Name	Remarks and Limitations
Feature Detection, Extraction, and Matching	
BRISKPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the "Introduction to Code Generation with Feature Matching and Registration" example.
cornerPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the "Introduction to Code Generation with Feature Matching and Registration" example.
`detectBRISKFeatures`	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
`detectFASTFeatures`	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
`detectHarrisFeatures`	Compile-time constant input: `'FilterSize'` Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
`detectMinEigenFeatures`	Compile-time constant input: `'FilterSize'` Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.

Name	Remarks and Limitations
`detectMSERFeatures`	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries "Portable C Code Generation for Functions That Use OpenCV Library" For code generation, the function outputs `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`.
`detectSURFFeatures`	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
`extractFeatures`	Compile-time constant input restrictions: `'Method'` Supports MATLAB Function block: Yes for `Block` method only. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries for `BRISK`, `FREAK`, and `SURF` Methods. "Portable C Code Generation for Functions That Use OpenCV Library"
`extractHOGFeatures`	Supports MATLAB Function block: No
`extractLBPFeatures`	Generates platform-dependent library: No Supports MATLAB Function block: Yes

Name	Remarks and Limitations
`matchFeatures`	Generates platform-dependent library: Yes for MATLAB host only when using the `Exhaustive` method. Generates portable C code for non-host target only when using the `Exhaustive` method. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries when not using the `Exhaustive` method. "Portable C Code Generation for Functions That Use OpenCV Library" Compile-time constant input: `'Method'` and `'Metric'`. Supports MATLAB Function block: No
MSERRegions	Supports MATLAB Function block: Yes For code generation, you must specify both the `pixellist` cell array and the `length` of each array, as the second input. The object outputs, `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`. Generated code for this function uses a precompiled platform-specific shared library.
SURFPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the "Introduction to Code Generation with Feature Matching and Registration" example.
Image Registration and Geometric Transformations	
`estimateGeometricTransform`	Supports MATLAB Function block: No
vision.GeometricShearer	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
Object Detection and Recognition	

Name	Remarks and Limitations
`ocr`	Compile-time constant input: `'TextLayout'`, `'Language'`, and `'CharacterSet'`. Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
ocrText	Supports MATLAB Function block: No
vision.PeopleDetector	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library" "System Objects in MATLAB Code Generation"
vision.CascadeObjectDetector	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries "Portable C Code Generation for Functions That Use OpenCV Library" "System Objects in MATLAB Code Generation"
Tracking and Motion Estimation	
`assignDetectionsToTracks`	Supports MATLAB Function block: Yes
opticalFlowFarneback	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. "Portable C Code Generation for Functions That Use OpenCV Library"
opticalFlowHS	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
opticalFlowLKDoG	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
opticalFlowLK	Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.

Name	Remarks and Limitations
vision.ForegroundDetector	Supports MATLAB Function block: No Generates platform-dependent library: Yes for MATLAB host. Generates portable C code for non-host target. Generated code for this function uses a precompiled platform-specific shared library. “System Objects in MATLAB Code Generation”
vision.HistogramBasedTracker	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.KalmanFilter	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.PointTracker	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”
vision.TemplateMatcher	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
Camera Calibration and Stereo Vision	
`bboxOverlapRatio`	Supports MATLAB Function block: No
`bbox2points`	Supports MATLAB® Function block: Yes
`disparity`	Compile-time constant input restriction: `'Method'`. Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”
`cameraMatrix`	Supports MATLAB Function block: No
`cameraPose`	Supports MATLAB Function block: No

Name	Remarks and Limitations
cameraParameters	Supports MATLAB Function block: No Use the toStruct method to pass a `cameraParameters` object into generated code. See the "Code Generation for Depth Estimation From Stereo Video" example.
`detectCheckerboardPoints`	Supports MATLAB Function block: No Code generation will not support specifying images as file names or cell arrays of file names. It supports only checkerboard detection in a single image or stereo pair of images. For example, these syntaxes are supported: • `detectCheckerboardPoints(I1)` • `detectCheckerobarPoints(I1,I2)` `I1` and `I2` are single grayscale or RGB images.
`generateCheckerboardPoints`	Supports MATLAB Function block: No
`epipolarline`	Supports MATLAB Function block: Yes
`estimateFundamentalMatrix`	Compile-time constant input restriction: `'Method'`, `'OutputClass'`, `'DistanceType'`, and `'ReportRuntimeError'`. Supports MATLAB Function block: Yes
`estimateUncalibratedRectification`	Supports MATLAB Function block: Yes
`extrinsics`	Supports MATLAB Function block: No
`isEpipoleInImage`	Supports MATLAB Function block: Yes
`lineToBorderPoints`	Supports MATLAB Function block: Yes
`reconstructScene`	Supports MATLAB Function block: No
`rectifyStereoImages`	Compile-time constant input restriction: `'interp'` and `'OutputView'` Supports MATLAB Function block: No
`rotationMatrixToVector`	Supports MATLAB Function block: Yes
`rotationVectorToMatrix`	Supports MATLAB Function block: Yes
`selectStrongestBbox`	Supports MATLAB Function block: No

Name	Remarks and Limitations
`stereoAnaglyph`	Supports MATLAB Function block: Yes
stereoParameters	Supports MATLAB Function block: No Use the toStruct method to pass a `stereoParameters` object into generated code. See the "Code Generation for Depth Estimation From Stereo Video" example.
`triangulate`	Supports MATLAB Function block: No
`undistortImage`	Compile-time constant input restriction: `'interp'` and `'OutputView'` Supports MATLAB Function block: No
Statistics	
vision.Autocorrelator	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.BlobAnalysis	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Crosscorrelator	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.LocalMaximaFinder	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Maximum	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Mean	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Median	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Minimum	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.StandardDeviation	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Variance	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
Filters, Transforms, and Enhancements	

Name	Remarks and Limitations
`integralImage`	Supports MATLAB Function block: Yes
vision.Convolver	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.DCT	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Deinterlacer	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.FFT	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.HoughLines	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.IDCT	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.IFFT	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.MedianFilter	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.Pyramid	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
Video Loading, Saving, and Streaming	
vision.DeployableVideoPlayer	Supports MATLAB Function block: Yes Generated code for this function uses a precompiled platform-specific shared library. "System Objects in MATLAB Code Generation"
vision.VideoFileReader	Supports MATLAB Function block: Yes Generated code for this function uses a precompiled platform-specific shared library. "System Objects in MATLAB Code Generation" Does not generate code for reading compressed images on the Mac.

Name	Remarks and Limitations
vision.VideoFileWriter	Supports MATLAB Function block: Yes Generated code for this function uses a precompiled platform-specific shared library. "System Objects in MATLAB Code Generation"
Color Space Formatting and Conversions	
vision.ChromaResampler	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.DemosaicInterpolator	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.GammaCorrector	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
Graphics	
`insertMarker`	Compile-time constant input: `'Shape'` and `'Color'` Supports MATLAB Function block: Yes
`insertShape`	Compile-time constant input: `'Color'` and `'SmoothEdges'` Supports MATLAB Function block: Yes
`insertObjectAnnotation`	Supports MATLAB Function block: Yes Limitation: Input image must be bounded, see "Specify Variable-Size Data Without Dynamic Memory Allocation" on page 48-5 "System Objects in MATLAB Code Generation"
`insertText`	Compile-time constant input: `Font`, `FontSize` Supports non-ASCII characters: No Supports MATLAB Function block: Yes
vision.AlphaBlender	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.MarkerInserter	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"
vision.ShapeInserter	Supports MATLAB Function block: Yes "System Objects in MATLAB Code Generation"

Control Flow in MATLAB

Function	Remarks and Limitations
`break`	—
`continue`	—
`end`	—
`for`	—
`if, elseif, else`	—
`parfor`	Treated as a `for`-loop in a `MATLAB Function` block.
`return`	—
`switch, case, otherwise`	• If all case expressions are scalar integer values, generates a C `switch` statement. At run time, if the switch value is not an integer, generates an error. • When the case expressions contain noninteger or nonscalar values, the code generation software generates C `if` statements in place of a C `switch` statement.
`while`	—

Data and File Management in MATLAB

Function	Remarks and Limitations
`computer`	• Information about the computer on which the code generation software is running. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`fclose`	—
`feof`	—

`fopen`	• Does not support:
	  • `machineformat`, `encoding`, or `fileID` inputs
	  • `message` output
	  • `fopen('all')`

Function	Remarks and Limitations

	• If you disable extrinsic calls, you cannot return `fileID`s created with `fopen` to MATLAB or extrinsic functions. You can use such `fileID`s only internally.
	• When generating C/C++ executables, static libraries, or dynamic libraries, you can open up to 20 files.
	• The generated code does not report errors from invalid file identifiers. Write your own file open error handling in your MATLAB code. Test whether `fopen` returns `-1`, which indicates that the file open failed. For example:
	`...`
	`fid = fopen(filename, 'r');`
	`if fid == -1`
	`  % fopen failed`
	`else`
	`% fopen successful, okay to call fread`
	`A = fread(fid);`
	`...`
	• The behavior of the generated code for `fread` is compiler-dependent if you:
	1 Open a file using `fopen` with a `permission` of `a+`.
	2 Read the file using `fread` before calling an I/O function, such as `fseek` or `frewind`, that sets the file position indicator.

Function	Remarks and Limitations

`fprintf`	• Does not support:
	  • `b` and `t` subtypes on `%u`, `%o` `%x`, and `%X` formats.
	  • `$` flag for reusing input arguments.
	  • printing arrays.
	• There is no automatic casting. Input arguments must match their format types for predictable results.
	• Escaped characters are limited to the decimal range of 0–127.
	• A call to `fprintf` with `fileID` equal to `1` or `2` becomes `printf` in the generated C/C++ code in the following cases:
	  • The `fprintf` call is inside a `parfor` loop.
	  • Extrinsic calls are disabled.
	• When the MATLAB behavior differs from the C compiler behavior, `fprintf` matches the C compiler behavior in the following cases:
	  • The format specifier has a corresponding C format specifier, for example, `%e` or `%E`.
	  • The `fprintf` call is inside a `parfor` loop.
	  • Extrinsic calls are disabled.
	• When you call `fprintf` with the format specifier `%s`, do not put a null character in the middle of the input string. Use `fprintf(fid, '%c', char(0))` to write a null character.
	• When you call `fprintf` with an integer format specifier, the type of the integer argument must be a type that the target hardware can represent as a native C type. For example, if you call `fprintf('%d', int64(n))`, the target hardware must have a native C type that supports a 64-bit integer.

Function	Remarks and Limitations

`fread`	• `precision` must be a constant.
	• The `source` and `output` that `precision` specifies cannot have values `long`, `ulong`, `unsigned long`, `bitN`, or `ubitN`.
	• You cannot use the `machineformat` input.
	• If the `source` or `output` that `precision` specifies is a C type, for example, `int`, the target and production sizes for that type must:
	  • Match.
	  • Map directly to a MATLAB type.
	• The `source` type that `precision` specifies must map directly to a C type on the target hardware.
	• If the `fread` call reads the entire file, all of the data must fit in the largest array available for code generation.
	• If `sizeA` is not constant or contains a nonfinite element, then dynamic memory allocation is required.
	• Treats a `char` value for `source` or `output` as a signed 8-bit integer. Use values between 0 and 127 only.
	• The generated code does not report file read errors. Write your own file read error handling in your MATLAB code. Test that the number of bytes read matches the number of bytes that you requested. For example:
	`...`
	`N = 100;`
	`[vals, numRead] = fread(fid, N, '*double');`
	`if numRead ~= N`
	`  % fewer elements read than expected`
	`end`
	`...`

`frewind`	—

Function	Remarks and Limitations
`load`	• Use only when generating MEX or code for Simulink simulation. To load compile-time constants, use `coder.load`. • Does not support use of the function without assignment to a structure or array. For example, use `S = load(filename)`, not `load(filename)`. • The output `S` must be the name of a structure or array without any subscripting. For example, `S(i) = load('myFile.mat')` is not allowed. • Arguments to `load` must be compile-time constant strings. • Does not support loading objects. • If the MAT-file contains unsupported constructs, use `load(filename,variables)` to load only the supported constructs. • You cannot use `save` in a function intended for code generation. The code generation software does not support the `save` function. Furthermore, you cannot use `coder.extrinsic` with `save`. Prior to generating code, you can use `save` to save the workspace data to a MAT-file. You must use `coder.varsize` to explicitly declare variable-size data loaded using the `load` function.

Data Types in MATLAB

Function	Remarks and Limitations
`cell`	"Cell Array Requirements and Limitations for Code Generation" on page 50-5
`deal`	—
`fieldnames`	Does not support objects. The input must be a structure.
`iscell`	—
`isfield`	Does not support cell arrays for the second argument.
`isobject`	—
`isstruct`	—

Function	Remarks and Limitations
`narginchk`	—
`nargoutchk`	—
`str2func`	• String must be constant/known at compile time
`struct`	• You cannot create a structure that contains a cell array. For example, you cannot generate code for: `s = struct('a',{{1 2}})` • If the `value` argument is a cell array, all elements must have the same type.
`struct2cell`	• For a variable-size structure array, the resulting cell array must be homogeneous. If `s` is a variable-size structure array, the fields must have the same type. • If `struct2cell` cannot convert `s` to a homogeneous cell array, the output cell array is heterogeneous. A heterogeneous output cell array can have a maximum of 1024 elements.
`structfun`	• Does not support the `ErrorHandler` option. • The number of outputs must be less than or equal to three.

Desktop Environment in MATLAB

Function	Remarks and Limitations
`ismac`	• Returns true or false based on the MATLAB version used for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`ispc`	• Returns true or false based on the MATLAB version you use for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.
`isunix`	• Returns true or false based on the MATLAB version used for code generation. • Use only when the code generation target is S-function (Simulation) or MEX-function.

Discrete Math in MATLAB

Function	Remarks and Limitations
`factor`	• The maximum double precision input is `2^33`. • The maximum single precision input is `2^25`. • The input `n` cannot have type `int64` or `uint64`.
`gcd`	—
`isprime`	• The maximum double precision input is `2^33`. • The maximum single precision input is `2^25`. • The input `X` cannot have type `int64` or `uint64`.
`lcm`	—
`nchoosek`	• When the first input, `x`, is a scalar, `nchoosek` returns a binomial coefficient. In this case, `x` must be a nonnegative integer. It cannot have type `int64` or `uint64`. • When the first input, `x`, is a vector, `nchoosek` treats it as a set. In this case, `x` can have type `int64` or `uint64`. • The second input, `k`, cannot have type `int64` or `uint64`. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`primes`	• The maximum double precision input is `2^32`. • The maximum single precision input is `2^24`. • The input `n` cannot have type `int64` or `uint64`.

DSP System Toolbox

C code generation for the following functions and System objects requires the DSP System Toolbox license. Many DSP System Toolbox functions require constant inputs for code generation.

Name	Remarks and Limitations
Estimation	
dsp.BurgAREstimator	"System Objects in MATLAB Code Generation"
dsp.BurgSpectrumEstimator	"System Objects in MATLAB Code Generation"

Name	Remarks and Limitations
dsp.CepstralToLPC	“System Objects in MATLAB Code Generation”
dsp.CrossSpectrumEstimator	“System Objects in MATLAB Code Generation”
dsp.LevinsonSolver	“System Objects in MATLAB Code Generation”
dsp.LPCToAutocorrelation	“System Objects in MATLAB Code Generation”
dsp.LPCToCepstral	“System Objects in MATLAB Code Generation”
dsp.LPCToLSF	“System Objects in MATLAB Code Generation”
dsp.LPCToLSP	“System Objects in MATLAB Code Generation”
dsp.LPCToRC	“System Objects in MATLAB Code Generation”
dsp.LSFToLPC	“System Objects in MATLAB Code Generation”
dsp.LSPToLPC	“System Objects in MATLAB Code Generation”
dsp.RCToAutocorrelation	“System Objects in MATLAB Code Generation”
dsp.RCToLPC	“System Objects in MATLAB Code Generation”
dsp.SpectrumEstimator	“System Objects in MATLAB Code Generation”
dsp.TransferFunctionEstimator	“System Objects in MATLAB Code Generation”
Filters	
`ca2tf`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`cl2tf`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
dsp.AdaptiveLatticeFilter	“System Objects in MATLAB Code Generation”
dsp.AffineProjectionFilter	“System Objects in MATLAB Code Generation”
dsp.AllpassFilter	“System Objects in MATLAB Code Generation” The System object supports code generation only when the `Structure` property is set to `Minimum multiplier` or `Lattice`.

Name	Remarks and Limitations
dsp.AllpoleFilter	• "System Objects in MATLAB Code Generation" • Only the `Denominator` property is tunable for code generation.
dsp.BiquadFilter	"System Objects in MATLAB Code Generation"
dsp.CICCompensationDecimator	"System Objects in MATLAB Code Generation"
dsp.CICCompensationInterpolator	"System Objects in MATLAB Code Generation"
dsp.CICDecimator	"System Objects in MATLAB Code Generation"
dsp.CICInterpolator	"System Objects in MATLAB Code Generation"
dsp.Differentiator	"System Objects in MATLAB Code Generation"
dsp.FarrowRateConverter	"System Objects in MATLAB Code Generation"
dsp.FastTransversalFilter	"System Objects in MATLAB Code Generation"
dsp.FilterCascade	• You cannot generate code directly from `dsp.FilterCascade`. You can use the `generateFilteringCode` method to generate a MATLAB function. You can generate C/C++ code from this MATLAB function. • "System Objects in MATLAB Code Generation"
dsp.FilteredXLMSFilter	"System Objects in MATLAB Code Generation"
dsp.FIRDecimator	"System Objects in MATLAB Code Generation"
dsp.FIRFilter	• "System Objects in MATLAB Code Generation" • Only the `Numerator` property is tunable for code generation.
dsp.FIRHalfbandDecimator	"System Objects in MATLAB Code Generation"
dsp.FIRHalfbandInterpolator	"System Objects in MATLAB Code Generation"
dsp.FIRInterpolator	"System Objects in MATLAB Code Generation"
dsp.FIRRateConverter	"System Objects in MATLAB Code Generation"
dsp.FrequencyDomainAdaptiveFilter	"System Objects in MATLAB Code Generation"

Name	Remarks and Limitations
dsp.HighpassFilter	"System Objects in MATLAB Code Generation"
dsp.IIRFilter	• Only the `Numerator` and `Denominator` properties are tunable for code generation. • "System Objects in MATLAB Code Generation"
dsp.IIRHalfbandDecimator	"System Objects in MATLAB Code Generation"
dsp.IIRHalfbandInterpolator	"System Objects in MATLAB Code Generation"
dsp.KalmanFilter	"System Objects in MATLAB Code Generation"
dsp.LMSFilter	"System Objects in MATLAB Code Generation"
dsp.LowpassFilter	"System Objects in MATLAB Code Generation"
dsp.RLSFilter	"System Objects in MATLAB Code Generation"
dsp.SampleRateConverter	"System Objects in MATLAB Code Generation"
dsp.SubbandAnalysisFilter	"System Objects in MATLAB Code Generation"
dsp.SubbandSynthesisFilter	"System Objects in MATLAB Code Generation"
dsp.VariableBandwidthFIRFilter	"System Objects in MATLAB Code Generation"
dsp.VariableBandwidthIIRFilter	"System Objects in MATLAB Code Generation"
`firceqrip`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`fireqint`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firgr`	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`firhalfband`	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Name	Remarks and Limitations
`firlpnorm`	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`firminphase`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firnyquist`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`firpr2chfb`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`ifir`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iircomb`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iirgrpdelay`	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`iirlpnorm`	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.

Name	Remarks and Limitations
`iirlpnormc`	• All inputs must be constant. Expressions or variables are allowed if their values do not change. • Does not support syntaxes that have cell array input.
`iirnotch`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`iirpeak`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`tf2ca`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`tf2cl`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
Filter Design	
`designMultirateFIR`	The inputs to the function must be constants
Math Operations	
dsp.ArrayVectorAdder	“System Objects in MATLAB Code Generation”
dsp.ArrayVectorDivider	“System Objects in MATLAB Code Generation”
dsp.ArrayVectorMultiplier	“System Objects in MATLAB Code Generation”
dsp.ArrayVectorSubtractor	“System Objects in MATLAB Code Generation”
dsp.CumulativeProduct	“System Objects in MATLAB Code Generation”
dsp.CumulativeSum	“System Objects in MATLAB Code Generation”

dsp.IFFT	"System Objects in MATLAB Code Generation"

Error Handling in MATLAB

Function	Remarks and Limitations
`assert`	• Generates specified error messages at compile time only if all input arguments are constants or depend on constants. Otherwise, generates specified error messages at run time. • For standalone code generation, excluded from the generated code.
`error`	For standalone code generation, excluded from the generated code.

Exponents in MATLAB

Function	Remarks and Limitations
`exp`	—
`expm`	—
`expm1`	—
`factorial`	—
`log`	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex.

Function	Remarks and Limitations
	To get the complex result, make the input value complex by passing in `complex(x)`.
`log2`	—
`log10`	—
`log1p`	—
`nextpow2`	—
`nthroot`	—
`reallog`	—
`realpow`	—
`realsqrt`	—
`sqrt`	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.

Filtering and Convolution in MATLAB

Function	Remarks and Limitations
`conv`	—
`conv2`	—
`convn`	—
`deconv`	—

`detrend`	• If supplied and not empty, the input argument `bp` must satisfy the following requirements:
	  • Be real.
	  • Be sorted in ascending order.
	  • Restrict elements to integers in the interval `[1, n-2]`. `n` is the number of elements in a column of input argument `X` , or the number of elements in `X` when `X` is a row vector.
	  • Contain all unique values.

Function	Remarks and Limitations
	• "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`filter`	—
`filter2`	—

Fixed-Point Designer

In addition to function-specific limitations listed in the table, the following general limitations apply to the use of Fixed-Point Designer functions in generated code, with `fiaccel`:

- `fipref` and `quantizer` objects are not supported.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fimath` or `numerictype` of a given `fi` variable after that variable has been created.
- The `boolean` value of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- You can use parallel for (`parfor`) loops in code compiled with `fiaccel`, but those loops are treated like regular `for` loops.
- When you compile code containing `fi` objects with nontrivial slope and bias scaling, you may see different results in generated code than you achieve by running the same code in MATLAB.
- The general limitations of C/C++ code generated from MATLAB apply. For more information, see "MATLAB Language Features Supported for C/C++ Code Generation".

Function	Remarks/Limitations
`abs`	N/A
`accumneg`	N/A
`accumpos`	N/A
`add`	• Code generation in MATLAB does not support the syntax `F.add(a,b)`. You must use the syntax `add(F,a,b)`.

Function	Remarks/Limitations
`all`	N/A
`any`	N/A
`atan2`	N/A
`bitand`	Not supported for slope-bias scaled `fi` objects.
`bitandreduce`	N/A
`bitcmp`	N/A
`bitconcat`	N/A
`bitget`	N/A
`bitor`	Not supported for slope-bias scaled `fi` objects.
`bitorreduce`	N/A
`bitreplicate`	N/A
`bitrol`	N/A
`bitror`	N/A
`bitset`	N/A
`bitshift`	N/A
`bitsliceget`	N/A
`bitsll`	Generated code may not handle out of range shifting.
`bitsra`	Generated code may not handle out of range shifting.
`bitsrl`	Generated code may not handle out of range shifting.
`bitxor`	Not supported for slope-bias scaled `fi` objects.
`bitxorreduce`	N/A
`ceil`	N/A
`complex`	N/A
`conj`	N/A

Function	Remarks/Limitations

`conv`	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
	• For variable-sized signals, you may see different results between generated code and MATLAB.
	  • In the generated code, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath`.
	  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when both inputs are nonscalar. However, if either input is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

`convergent`	N/A
`cordicabs`	Variable-size signals are not supported.
`cordicangle`	Variable-size signals are not supported.
`cordicatan2`	Variable-size signals are not supported.
`cordiccart2pol`	Variable-size signals are not supported.
`cordiccexp`	Variable-size signals are not supported.
`cordiccos`	Variable-size signals are not supported.
`cordicpol2cart`	Variable-size signals are not supported.
`cordicrotate`	Variable-size signals are not supported.
`cordicsin`	Variable-size signals are not supported.
`cordicsincos`	Variable-size signals are not supported.
`cordicsqrt`	Variable-size signals are not supported.
`cos`	N/A
`ctranspose`	N/A
`diag`	If supplied, the index, k, must be a real and scalar integer value that is not a `fi` object.

Function	Remarks/Limitations
`divide`	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object. • Complex and imaginary divisors are not supported. • Code generation in MATLAB does not support the syntax `T.divide(a,b)`.
`double`	For the automated workflow, do not use explicit double or single casts in your MATLAB algorithm to insulate functions that do not support fixed-point data types. The automated conversion tool does not support these casts. Instead of using casts, supply a replacement function. For more information, see “Function Replacements”.
`end`	N/A
`eps`	• Supported for scalar fixed-point signals only. • Supported for scalar, vector, and matrix, `fi` single and `fi` double signals.
`eq`	Not supported for fixed-point signals with different biases.
`fi`	• The default constructor syntax without any input arguments is not supported. • If the `numerictype` is not fully specified, the input to `fi` must be a constant, a `fi`, a single, or a built-in integer value. If the input is a built-in double value, it must be a constant. This limitation allows `fi` to autoscale its fraction length based on the known data type of the input. • All properties related to data type must be constant for code generation. • `numerictype` object information must be available for nonfixed-point Simulink inputs.
`filter`	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.

Function	Remarks/Limitations
`fimath`	• Fixed-point signals coming in to a MATLAB Function block from Simulink are assigned a `fimath` object. You define this object in the MATLAB Function block dialog in the Model Explorer. • Use to create `fimath` objects in the generated code. • If the `ProductMode` property of the `fimath` object is set to anything other than `FullPrecision`, the `ProductWordLength` and `ProductFractionLength` properties must be constant. • If the `SumMode` property of the `fimath` object is set to anything other than `FullPrecision`, the `SumWordLength` and `SumFractionLength` properties must be constant.
`fix`	N/A
`fixed.Quantizer`	N/A
`flip`	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`fliplr`	N/A
`flipud`	N/A
`floor`	N/A
`for`	N/A
`ge`	Not supported for fixed-point signals with different biases.
`get`	The syntax `structure = get(o)` is not supported.
`getlsb`	N/A
`getmsb`	N/A
`gt`	Not supported for fixed-point signals with different biases.
`horzcat`	N/A
`imag`	N/A
`int8`, `int16`, `int32`, `int64`	N/A
`ipermute`	N/A
`iscolumn`	N/A
`isempty`	N/A

Function	Remarks/Limitations
`isequal`	N/A
`isfi`	Avoid using the `isfi` function in code that you intend to convert using the automated workflow. The value returned by `isfi` in the fixed-point code might differ from the value returned in the original MATLAB algorithm. The behavior of the fixed-point code might differ from the behavior of the original algorithm.
`isfimath`	N/A
`isfimathlocal`	N/A
`isfinite`	N/A
`isinf`	N/A
`isnan`	N/A
`isnumeric`	N/A
`isnumerictype`	N/A
`isreal`	N/A
`isrow`	N/A
`isscalar`	N/A
`issigned`	N/A
`isvector`	N/A
`le`	Not supported for fixed-point signals with different biases.
`length`	N/A
`logical`	N/A
`lowerbound`	N/A
`lsb`	• Supported for scalar fixed-point signals only. • Supported for scalar, vector, and matrix, `fi` single and double signals.
`lt`	Not supported for fixed-point signals with different biases.
`max`	N/A
`mean`	N/A
`median`	N/A

Function	Remarks/Limitations
`min`	N/A
`minus`	Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object.

`mpower`	• When the exponent `k` is a variable and the input is a scalar, the `ProductMode` property of the governing `fimath` must be `SpecifyPrecision`.
	• When the exponent `k` is a variable and the input is not scalar, the `SumMode` property of the governing `fimath` must be `SpecifyPrecision`.
	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `SpecifyPrecision` or `Keep LSB`.
	• For variable-sized signals, you may see different results between the generated code and MATLAB.
	  • In the generated code, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath`.
	  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when the first input, `a`, is nonscalar. However, when `a` is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

`mpy`	• Code generation in MATLAB does not support the syntax `F.mpy(a,b)`. You must use the syntax `mpy(F,a,b)`. • When you provide complex inputs to the `mpy` function inside of a MATLAB Function block, you must declare the input as complex before running the simulation. To do so, go to the **Ports and data manager** and set the **Complexity** parameter for all known complex inputs to `On`.
`mrdivide`	N/A

Function	Remarks/Limitations

`mtimes`	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object.
	• Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `SpecifyPrecision` or `KeepLSB`.
	• For variable-sized signals, you may see different results between the generated code and MATLAB.
	  • In the generated code, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath`.
	  • In MATLAB, the output for variable-sized signals is computed using the `SumMode` property of the governing `fimath` when both inputs are nonscalar. However, if either input is a scalar, MATLAB computes the output using the `ProductMode` of the governing `fimath`.

`ndims`	N/A
`ne`	Not supported for fixed-point signals with different biases.
`nearest`	N/A
`numberofelements`	`numberofelements` will be removed in a future release. Use `numel` instead.
`numel`	N/A
`numerictype`	• Fixed-point signals coming in to a MATLAB Function block from Simulink are assigned a `numerictype` object that is populated with the signal's data type and scaling information. • Returns the data type when the input is a nonfixed-point signal. • Use to create `numerictype` objects in generated code. • All `numerictype` object properties related to the data type must be constant.
`permute`	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`plus`	Any non-`fi` inputs must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object.
`pow2`	N/A

Function	Remarks/Limitations
`power`	When the exponent `k` is a variable, the `ProductMode` property of the governing `fimath` must be `SpecifyPrecision`.
`qr`	N/A
`quantize`	N/A
`range`	N/A
`rdivide`	N/A
`real`	N/A
`realmax`	N/A
`realmin`	N/A
`reinterpretcast`	N/A
`removefimath`	N/A
`repmat`	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`rescale`	N/A
`reshape`	N/A
`rot90`	In the syntax `rot90(A,k)`, the argument `k` must be a built-in type; it cannot be a `fi` object.
`round`	N/A
`setfimath`	N/A
`sfi`	• All properties related to data type must be constant for code generation.
`shiftdim`	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`sign`	N/A
`sin`	N/A
`single`	For the automated workflow, do not use explicit double or single casts in your MATLAB algorithm to insulate functions that do not support fixed-point data types. The automated conversion tool does not support these casts. Instead of using casts, supply a replacement function. For more information, see “Function Replacements”.

Function	Remarks/Limitations
`size`	N/A
`sort`	The dimensions argument must be a built-in type; it cannot be a `fi` object.
`squeeze`	N/A
`sqrt`	• Complex and [Slope Bias] inputs error out. • Negative inputs yield a 0 result.
`storedInteger`	N/A
`storedIntegerToDouble`	N/A
`sub`	• Code generation in MATLAB does not support the syntax `F.sub(a,b)`. You must use the syntax `sub(F,a,b)`.
`subsasgn`	N/A
`subsref`	N/A
`sum`	Variable-sized inputs are only supported when the `SumMode` property of the governing `fimath` is set to `Specify precision` or `Keep LSB`.
`times`	• Any non-`fi` input must be constant; that is, its value must be known at compile time so that it can be cast to a `fi` object. • When you provide complex inputs to the `times` function inside of a MATLAB Function block, you must declare the input as complex before running the simulation. To do so, go to the **Ports and data manager** and set the **Complexity** parameter for all known complex inputs to `On`.
`transpose`	N/A
`tril`	If supplied, the index, *k*, must be a real and scalar integer value that is not a `fi` object.
`triu`	If supplied, the index, *k*, must be a real and scalar integer value that is not a `fi` object.
`ufi`	• All properties related to data type must be constant for code generation.
`uint8`, `uint16`, `uint32`, `uint64`	N/A
`uminus`	N/A

Function	Remarks/Limitations
`uplus`	N/A
`upperbound`	N/A
`vertcat`	N/A

HDL Coder

Function	Remarks and Limitations
hdl.RAM	This System object is available with MATLAB.

Histograms in MATLAB

Function	Remarks and Limitations

`hist`	• Histogram bar plotting not supported. Call with at least one output argument.
	• If supplied, the second argument `x` must be a scalar constant.
	• Inputs must be real.
	
	For the syntax `[nout, xout] = hist(y,x)`:
	
	• When `y` is a fixed-size vector or variable-length vector:
	  • `nout` is always a row vector.
	  • If `x` is a vector, `xout` is a vector with the same orientation as `x`.
	  • If `x` is a scalar (fixed-size), `xout` is a row vector.
	• `nout` and `xout` are column vectors when the following conditions are true:
	  • `y` is a matrix
	  • `size(y,1)` and `size(y,2)` do not have fixed length 1
	  • One of `size(y,1)` and `size(y,2)` has length 1 at run time
	• A variable-size`x` is interpreted as a vector input even if it is a scalar at run time.
	• If at least one of the inputs is empty, vector orientations in the output can differ from MATLAB.

Function	Remarks and Limitations
`histc`	• The output of a variable-size array that becomes a column vector at run time is a column-vector, not a row-vector. • If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Image Acquisition Toolbox

If you install Image Acquisition Toolbox software, you can generate C and C++ code for the VideoDevice System object. See `imaq.VideoDevice` and "Code Generation with VideoDevice System Object".

Image Processing in MATLAB

Function	Remarks and Limitations
`im2double`	—
`rgb2gray`	—

Image Processing Toolbox

The following table lists the Image Processing Toolbox functions that have been enabled for code generation. You must have the MATLAB Coder software installed to generate C code from MATLAB for these functions.

Image Processing Toolbox provides three types of code generation support:

- Functions that generate C code.
- Functions that generate C code that depends on a platform-specific shared library (`.dll`, `.so`, or `.dylib`). Use of a shared library preserves performance optimizations in these functions, but this limits the target platforms for which you can generate code. For more information, see "Code Generation for Image Processing".
- Functions that generate C code or C code that depends on a shared library, depending on which target platform you specify in MATLAB Coder. If you specify the generic `MATLAB Host Computer` target platform, these functions generate C code that depends on a shared library. If you specify any other target platform, these functions generate C code.

In generated code, each supported toolbox function has the same name, arguments, and functionality as its Image Processing Toolbox counterpart. However, some functions have limitations. The following table includes information about code generation limitations that might exist for each function. In the following table, all the functions generate C code. The table identifies those functions that generate C code that depends on a shared library, and those functions that can do both, depending on which target platform you choose.

Function	Remarks/Limitations
`adaptthresh`	The `ForegroundPolarity` and `Statistic` arguments must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The `NeighborhoodSize` argument must be a compile-time constant.
affine2d	When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`boundarymask`	The `conn` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwareaopen`	`BW` must be a 2-D binary image. N-D arrays are not supported. `conn` can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. `conn` must be a compile-time constant. MATLAB Function Block support: No.
`bwboundaries`	The `conn` and `options` arguments must be compile-time constants and the return value `A` can only be a full matrix, not a sparse matrix. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library.

Function	Remarks/Limitations
	MATLAB Function Block support: No.
`bwconncomp`	The input image must be 2-D. The `conn` argument must be a compile-time constant and the only connectivities supported are 4 or 8. You can specify connectivity as a 3-by-3 matrix, but it can only be `[0 1 0;1 1 1;0 1 0]` or `ones(3)`. The `CC` struct return value does not include the `PixelIdxList` field. MATLAB Function Block support: No.
`bwdist`	The `method` argument must be a compile-time constant. Input images must have fewer than 2^{32} pixels. Generated code for this function uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bweuler`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwlabel`	When generating code, the parameter `n` must be a compile-time constant. MATLAB Function Block support: No.
`bwlookup`	For best results, specify an input image of class `logical`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`bwmorph`	The text string specifying the operation must be a constant and, for best results, specify an input image of class `logical`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`bwpack`	Generated code for this function uses a precompiled platform-specific shared library. MATLAB Function Block support: Yes.
`bwperim`	Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwselect`	Supports only the 3 and 4 input argument syntaxes: `BW2 = bwselect(BW,c,r)` and `BW2 = bwselect(BW,c,r,n)`. The optional fourth input argument, `n`, must be a compile-time constant. In addition, with code generation, `bwselect` only supports only the 1 and 2 output argument syntaxes: `BW2 = bwselect(___)` or `[BW2, idx] = bwselect(___)`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`bwtraceboundary`	The `dir`, `fstep`, and `conn` arguments must be compile-time constants. MATLAB Function Block support: No.

Function	Remarks/Limitations
`bwunpack`	Generated code for this function uses a precompiled platform-specific shared library. MATLAB Function Block support: Yes. The input argument `M` must be a compile-time constant.
`conndef`	Input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`demosaic`	The `sensorAlignment` argument must be a compile-time constant. MATLAB Function Block support: Yes.
`edge`	The `method`, `direction`, and `sigma` arguments must be a compile-time constants. In addition, nonprogrammatic syntaxes are not supported. For example, the syntax `edge(im)`, where `edge` does not return a value but displays an image instead, is not supported. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input arguments `thresh` and `sigma` must be compile-time constants.
`fitgeotrans`	The `transformtype` argument must be a compile-time constant. The function supports the following transformation types: `'nonreflectivesimilarity'`, `'similarity'`, `'affine'`, or `'projective'`. MATLAB Function Block support: Yes.
`fspecial`	Inputs must be compile-time constants. Expressions or variables are allowed if their values do not change. MATLAB Function Block support: Yes. The input arguments `hsize`, `radius`, `len`, and `theta` must be compile-time constants.
`getrangefromclass`	MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`grayconnected`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`histeq`	All the syntaxes that include indexed images are not supported. This includes all syntaxes that accept `map` as input and return `newmap`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be a compile-time constant.
`hough`	The optional parameter names `'Theta'` and `'RhoResolution'` must be compile-time string constants. The optional `Theta` vector must have a bounded size. MATLAB Function Block support: Yes. The input argument `BW` must be fixed size, the `RhoResolution` parameter must be a compile-time constant, and the `Theta` vector must have a bounded size.
`houghlines`	The optional parameter names `'FillGap'` and `'MinLength'` must be compile-time string constants. Their associated values need not be compile-time constants. MATLAB Function Block support: No.
`houghpeaks`	The optional parameter names `'Threshold'` and `'NHoodSize'` must be compile-time string constants. Their associated values need not be compile-time constants. MATLAB Function Block support: Yes.
`im2int16`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`im2uint8`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`im2uint16`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`im2single`	MATLAB Function Block support: Yes.
`im2double`	MATLAB Function Block support: Yes.
`imabsdiff`	MATLAB Function Block support: Yes.
`imadjust`	Does not support syntaxes that include indexed images. This includes all syntaxes that accept `map` as input and return `newmap`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imbinarize`	String input arguments must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imbothat`	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imboxfilt`	MATLAB Function Block support: Yes.
`imclearborder`	The optional second input argument, `conn`, must be a compile-time constant. Supports only up to 3-D inputs. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`imclose`	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imcomplement`	Does not support `int64` and `uint64` data types. MATLAB Function Block support: Yes.
`imcrop`	The interactive syntaxes, such as `I2 = imcrop`, are not supported. Indexed images are not supported, including the noninteractive syntax `X2 = imcrop(X,map,rect);`. MATLAB Function Block support: Yes.
`imdilate`	The input image `IM` must be either 2-D or 3-D image. The `SE`, `PACKOPT`, and `SHAPE` input arguments must be a compile-time constant. The structuring element argument `SE` must be a single element—arrays of structuring elements are not supported. To obtain the same result as that obtained using an array of structuring elements, call the function sequentially. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imerode`	The input image `IM` must be either 2-D or 3-D image. The `SE`, `PACKOPT`, and `SHAPE` input arguments must be a compile-time constant. The structuring element argument `SE` must be a single element—arrays of structuring elements are not supported. To obtain the same result as that obtained using an array of structuring elements, call the function sequentially. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`imextendedmax`	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imextendedmin`	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imfill`	The optional input connectivity, `conn` and the string `'holes'` must be compile-time constants. Supports only up to 3-D inputs. The interactive mode to select points, `imfill(BW,0,CONN)` is not supported in code generation. `locations` can be a *P*-by-1 vector, in which case it contains the linear indices of the starting locations. `locations` can also be a *P*-by-`ndims(I)` matrix, in which case each row contains the array indices of one of the starting locations. Once you select a format at compile-time, you cannot change it at run time. However, the number of points in locations can be varied at run time. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`imfilter`	The input image can be either 2-D or 3-D. The value of the input argument, `options`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imfindcircles`	All string input arguments and values must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`imgaborfilt`	MATLAB Function Block support: No.
`imgaussfilt`	String input arguments must be compile-time constants. When `FilterDomain` is `'spatial'`, if you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imgradient3`	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`imgradientxyz`	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`imhist`	The optional second input argument, `n`, must be a compile-time constant. In addition, nonprogrammatic syntaxes are not supported. For example, the syntaxes where `imhist` displays the histogram are not supported. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be a compile-time constant.

Function	Remarks/Limitations
`imhmax`	The optional third input argument, `conn`, must be a compile-time constant If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imhmin`	The optional third input argument, `conn`, must be a compile-time constant If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imlincomb`	The `output_class` argument must be a compile-time constant. You can specify up to four input image arguments. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`immse`	MATLAB Function Block support: Yes.
`imopen`	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imoverlay`	If you specify the `'color'` argument as a string, it must be a compile-time constant. MATLAB Function Block support: Yes.
`impyramid`	The `direction` argument must be a compile-time constant. MATLAB Function Block support: Yes. The input argument direction must be a compile-time constant.

Function	Remarks/Limitations
`imquantize`	MATLAB Function Block support: Yes.
`imread`	Supports reading of 8-bit JPEG images only. The file name input argument must be a valid absolute path or relative path. This function generates code that uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The file name input argument must be a compile-time constant.
`imreconstruct`	The optional third input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
imref2d	The `XWorldLimits`, `YWorldLimits` and `ImageSize` properties can be set only during object construction. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
imref3d	The `XWorldLimits`, `YWorldLimits`, `ZWorldLimits` and `ImageSize` properties can be set only during object construction. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`imregionalmax`	The optional second input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`imregionalmin`	The optional second input argument, `conn`, must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imresize`	Does not support indexed images or custom interpolation kernels. All parameter-value pair input arguments must be compile-time constants. MATLAB Function Block support: Yes. The input arguments `Scale` and `method` must be compile-time constants, and the values of the `OutputSize` parameter, `numrows` and `numcols`, must be compile-time constants.
`imrotate`	The `method` and `bbox` input argument values must be compile-time constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `angle` must be a compile-time constant.
`imtophat`	The input image `IM` must be either 2-D or 3-D image. The structuring element input argument `SE` must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`imtranslate`	The supports only 2-D translation vectors. 3-D translations are not supported If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `translation` must be a compile-time constant.

Function	Remarks/Limitations
`imwarp`	The geometric transformation object input, `tform`, must be either `affine2d` or `projective2d`. Additionally, the interpolation method and optional parameter names must be string constants. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `tform` must be a compile-time constant.
`integralBoxFilter`	The `'NormalizationFactor'` parameter must be a compile-time constant. MATLAB Function Block support: Yes. The input argument `filtersize` must be a compile-time constant.
`intlut`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`iptcheckconn`	Input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`iptcheckmap`	MATLAB Function Block support: Yes.
`lab2rgb`	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`label2idx`	MATLAB Function Block support: No.

Function	Remarks/Limitations
`label2rgb`	Referring to the standard syntax: `RGB = label2rgb(L, map, zerocolor, order)` • Submit at least two input arguments: the label matrix, `L`, and the colormap matrix, `map`. • `map` must be an `n-by-3`, `double`, colormap matrix. You cannot use a string containing the name of a MATLAB colormap function or a function handle of a colormap function. • If you set the boundary color `zerocolor` to the same color as one of the regions, `label2rgb` will not issue a warning. • If you supply a value for `order`, it must be `'noshuffle'`. MATLAB Function Block support: Yes.
`mean2`	MATLAB Function Block support: Yes.
`medfilt2`	The `padopt` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The neighborhood size input argument must be a compile-time constant.
`multithresh`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument `N` must be compile-time constant.
offsetstrel	The `'ball'` input argument and all other input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
`ordfilt2`	The `padopt` argument must be a compile-time constant. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`otsuthresh`	MATLAB Function Block support: Yes.
`padarray`	Support only up to 3-D inputs. Input arguments, `padval` and `direction` are expected to be compile-time constants. MATLAB Function Block support: Yes. The input argument `padsize` must be a compile-time constant.
projective2d	When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`psnr`	MATLAB Function Block support: Yes.
`regionprops`	Supports only 2-D images. Does not support the table output type. Does not accept cell arrays as input—use a comma-separated list instead. Does not support the properties `ConvexArea`, `ConvexHull`, `ConvexImage`, `Solidity`, and `SubarrayIdx`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`rgb2gray`	MATLAB Function Block support: Yes.
`rgb2lab`	String input arguments must be compile-time constants. MATLAB Function Block support: Yes.
`rgb2ycbcr`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Function	Remarks/Limitations
strel	All of the input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
`stretchlim`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
`superpixels`	String input arguments must be compile-time constants. The value of `'IsInputLab'` (true or false) must be a compile-time constant. MATLAB Function Block support: No.
`watershed`	Supports only 2-D images. Supports only 4- or 8-connectivity. Supports only up to 65,535 regions. The output type is always `uint16`. If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
`ycbcr2rgb`	If you choose the generic `MATLAB Host Computer` target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Input and Output Arguments in MATLAB

Function	Remarks and Limitations
`nargin`	—
`nargout`	• For a function with no output arguments, returns `1` if called without a terminating semicolon. **Note:** This behavior also affects extrinsic calls with no terminating semicolon. `nargout` is `1` for the called function in MATLAB.

Interpolation and Computational Geometry in MATLAB

Function	Remarks and Limitations
`cart2pol`	—
`cart2sph`	—
`interp1`	• Does not support the `'cubic'` method. Instead, use `'v5cubic'` or `'spline'`. • The input argument `x` (sample points) must be strictly increasing or strictly decreasing. Indices are not reordered. • If the input argument `v` (sample values) is a variable-length vector (1-by-`:` or `:`-by-1), the shape of the output `vq` matches the shape in MATLAB. If the input argument `v` is variable-size, is not a variable-length vector, and becomes a row vector at run time, an error occurs. • If the input argument `xq` (query points) is variable-size, is not a variable-length vector, and becomes a row or column vector at run time, an error occurs. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`interp1q`	Might not match MATLAB when some `Y` values are `Inf` or `NaN`.

`interp2`	• `Xq` and `Yq` must be the same size. Use `meshgrid` to evaluate on a grid.
	• For best results, provide `X` and `Y` as vectors.
	• For the `'cubic'` method, reports an error if the grid does not have uniform spacing. In this case, use the `'spline'` method.
	• For best results when you use the `'spline'` method:
	  • Use `meshgrid` to create the inputs `Xq` and `Yq`.
	  • Use a small number of interpolation points relative to the dimensions of `V`. Interpolating over a large set of scattered points can be inefficient.

`interp3`	• `Xq`, `Yq`, and `Zq` must be the same size. Use `meshgrid` to evaluate on a grid. • For best results, provide `X`, `Y`, and `Z` as vectors.

Function	Remarks and Limitations

	• For the `'cubic'` method, reports an error if the grid does not have uniform spacing. In this case, use the `'spline'` method.
	• For best results when you use the `'spline'` method:
	  • Use `meshgrid` to create the inputs `Xq`, `Yq`, and `Zq`.
	  • Use a small number of interpolation points relative to the dimensions of `V`. Interpolating over a large set of scattered points can be inefficient.

`interpn`	• For best results, provide `X1,X2,...,Xn` as vectors. • Does not support the `'cubic'` or `'spline'` methods for 2-D and higher interpolation. • The interpolation method must be a constant string.
`meshgrid`	—

Function	Remarks and Limitations

`mkpp`	• The output structure `pp` differs from the `pp` structure in MATLAB. In MATLAB, `ppval` cannot use the `pp` structure from the code generation software. For code generation, `ppval` cannot use a `pp` structure created by MATLAB. `unmkpp` can use a MATLAB `pp` structure for code generation.
	
	To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
	
	  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
	  • In MATLAB, use `mkpp` to create the `pp` structure.
	• If you do not provide `d`, then `coefs` must be two-dimensional and have a fixed number of columns. In this case, the number of columns is the order.
	• To define a piecewise constant polynomial, `coefs` must be a column vector or `d` must have at least two elements.
	• If you provide `d` and `d` is `1`, `d` must be a constant. Otherwise, if the input to `ppval` is nonscalar, the shape of the output of `ppval` can differ from `ppval` in MATLAB.
	• If you provide `d`, it must have a fixed length. One of the following sets of statements must be true:
	
	1 Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
	
	`size(coefs,j) = d(j)`
	`size(coefs,m+1) = npieces`
	`size(coefs,m+2) = order`
	`j` = 1,2,...,m. The dimension `m+2` must be fixed length.
	
	2 Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
	
	`size(coefs,1) = prod(d)*npieces`
	`size(coefs,2) = order`
	The second dimension must be fixed length.
	• If you do not provide `d`, the following statements must be true:

Function	Remarks and Limitations

	Suppose that `m = length(d)` and `npieces = length(breaks) - 1`.
	
	`size(coefs,1) = prod(d)*npieces`
	`size(coefs,2) = order`
	The second dimension must be fixed length.

`pchip`	• Input `x` must be strictly increasing.
	• Does not remove `y` entries with `NaN` values.
	• If you generate code for the `pp = pchip(x,y)` syntax, you cannot input `pp` to the `ppval` function in MATLAB. To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
	  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
	  • In MATLAB, use `mkpp` to create the `pp` structure.

`pol2cart`	—
`polyarea`	—
`ppval`	The size of output `v` does not match MATLAB when both of the following statements are true: • The input `x` is a variable-size array that is not a variable-length vector. • `x` becomes a row vector at run time. The code generation software does not remove the singleton dimensions. However, MATLAB might remove singleton dimensions. For example, suppose that `x` is a :4-by-:5 array (the first dimension is variable size with an upper bound of 4 and the second dimension is variable size with an upper bound of 5). Suppose that `ppval(pp,0)` returns a 2-by-3 fixed-size array. `v` has size 2-by-3-by-:4-by-:5. At run time, suppose that, size(x,1) =1 and size (x,2) = 5. In the generated code, the size(v) is [2,3,1,5]. In MATLAB, the size is [2,3,5].
`rectint`	—
`sph2cart`	—

Function	Remarks and Limitations

`spline`	• Input `x` must be strictly increasing.
	• Does not remove `Y` entries with `NaN` values.
	• Does not report an error for infinite endslopes in `Y`.
	• If you generate code for the `pp = spline(x,Y)` syntax, you cannot input `pp` to the `ppval` function in MATLAB. To create a MATLAB `pp` structure from a `pp` structure created by the code generation software:
	  • In code generation, use `unmkpp` to return the piecewise polynomial details to MATLAB.
	  • In MATLAB, use `mkpp` to create the `pp` structure.

`unmkpp`	• `pp` must be a valid piecewise polynomial structure created by `mkpp`, `spline`, or `pchip` in MATLAB or by the code generation software. • Does not support `pp` structures created by `interp1` in MATLAB.

Linear Algebra in MATLAB

Function	Remarks and Limitations
`bandwidth`	—
`isbanded`	—
`isdiag`	—
`ishermitian`	—
`istril`	—
`istriu`	—
`issymmetric`	—

`linsolve`	• The option structure must be a constant.
	• Supports only a scalar option structure input. It does not support arrays of option structures.
	• Only optimizes these cases:
	  • `UT`
	  • `LT`

Function	Remarks and Limitations
	• `UHESS` = `true` (the `TRANSA` can be either `true` or `false`) • `SYM` = `true` and `POSDEF` = `true` Other options are equivalent to using `mldivide`.
`lsqnonneg`	• You must enable support for variable-size arrays. • The `message` string in the output structure `output` (the fifth output) is not translated.
`null`	• Might return a different basis than MATLAB • Does not support rational basis option (second input)
`orth`	• Can return a different basis than MATLAB
`rsf2csf`	—
`schur`	Can return a different Schur decomposition in generated code than in MATLAB.
`sqrtm`	—

Logical and Bit-Wise Operations in MATLAB

Function	Remarks and Limitations
`and`	—
`bitand`	—
`bitcmp`	—
`bitget`	—
`bitor`	—
`bitset`	—
`bitshift`	—
`bitxor`	—
`not`	—
`or`	—
`xor`	—

MATLAB Compiler

C and C++ code generation for the following functions requires the MATLAB Compiler software.

Function	Remarks and Limitations
`isdeployed`	• Returns true and false as appropriate for MEX and SIM targets • Returns false for other targets
`ismcc`	• Returns true and false as appropriate for MEX and SIM targets. • Returns false for other targets.

Matrices and Arrays in MATLAB

Function	Remarks and Limitations
`abs`	—
`all`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`angle`	—
`any`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`blkdiag`	—
`bsxfun`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cat`	• Does not support concatenation of cell arrays. • If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`circshift`	Does not support cell arrays for the first argument.
`colon`	• Does not accept complex inputs. • The input `i` cannot have a logical value. • Does not accept vector inputs. • Inputs must be constants. • Uses single-precision arithmetic to produce single-precision results.

Function	Remarks and Limitations
`compan`	—
`cond`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cov`	• If the input is variable-size and is `[]` at run time, returns `[]` not `NaN`. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cross`	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`cumprod`	Does not support logical inputs. Cast input to `double` first.
`cumsum`	Does not support logical inputs. Cast input to `double` first.
`det`	—

Function	Remarks and Limitations

`diag`	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
	• For variable-size inputs that are variable-length vectors (1-by-: or :-by-1), `diag`:
	  • Treats the input as a vector input.
	  • Returns a matrix with the given vector along the specified diagonal.
	• For variable-size inputs that are not variable-length vectors, `diag`:
	  • Treats the input as a matrix.
	  • Does not support inputs that are vectors at run time.
	  • Returns a variable-length vector.
	  If the input is variable-size (:m-by-:n) and has shape 0-by-0 at run time, the output is 0-by-1 not 0-by-0. However, if the input is a constant size 0-by-0, the output is `[]`.
	• For variable-size inputs that are not variable-length vectors (1-by-: or :-by-1), `diag` treats the input as a matrix from which to extract a diagonal vector. This behavior occurs even if the input array is a vector at run time. To force `diag` to build a matrix from variable-size inputs that are not 1-by-: or :-by-1, use:
	  • `diag(x(:))` instead of `diag(x)`
	  • `diag(x(:),k)` instead of `diag(x,k)`
	• "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

`diff`	• If supplied, the arguments representing the number of times to apply `diff` and the dimension along which to calculate the difference must be constants. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`dot`	—

Function	Remarks and Limitations
`eig`	• For code generation,`QZ` algorithm is used in all cases. MATLAB can use different algorithms for different inputs. Consequently, `V` might represent a different basis of eigenvectors. The eigenvalues in `D` might not be in the same order as in MATLAB. • With one input, `[V,D] = eig(A)`, the results are similar to those obtained using `[V,D] = eig(A,eye(size(A)),'qz')` in MATLAB, except that the columns of `V` are normalized. • Options `'balance'`, and `'nobalance'` are not supported for the standard eigenvalue problem. `'chol'` is not supported for the symmetric generalized eigenvalue problem. • Outputs are of complex type. • Does not support the option to calculate left eigenvectors.
`eye`	• `classname` must be a built-in MATLAB numeric type. Does not invoke the static `eye` method for other classes. For example, `eye(m, n, 'myclass')` does not invoke `myclass.eye(m,n)`. • Size arguments must have a fixed size.
`false`	• Dimensions must be real, nonnegative, integers.
`find`	• Issues an error if a variable-size input becomes a row vector at run time. **Note:** This limitation does not apply when the input is scalar or a variable-length row vector. • For variable-size inputs, the shape of empty outputs, 0-by-0, 0-by-1, or 1-by-0, depends on the upper bounds of the size of the input. The output might not match MATLAB when the input array is a scalar or [] at run time. If the input is a variable-length row vector, the size of an empty output is 1-by-0, otherwise it is 0-by-1. • Always returns a variable-length vector. Even when you provide the output vector `k`, the output cannot be fixed-size because the output can contain fewer than k elements. For example, `find(x,1)` returns a variable-length vector with 1 or 0 elements.
`flip`	Does not support cell arrays for the first argument.
`flipdim`	Does not support cell arrays for the first argument.

Function	Remarks and Limitations
`fliplr`	Does not support cell arrays.
`flipud`	Does not support cell arrays.
`full`	—
`hadamard`	`n` must be a fixed-size scalar.
`hankel`	—
`hilb`	—
`ind2sub`	• The first argument should be a valid size vector. Size vectors for arrays with more than `intmax` elements are not supported. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`inv`	Singular matrix inputs can produce nonfinite values that differ from MATLAB results.
`invhilb`	—
`ipermute`	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`iscolumn`	—
`isempty`	—
`isequal`	—
`isequaln`	—
`isfinite`	—
`isfloat`	—
`isinf`	—
`isinteger`	—
`islogical`	—
`ismatrix`	—
`isnan`	—
`isrow`	—
`issparse`	—

Function	Remarks and Limitations
`isvector`	—
`kron`	—
`length`	—
`linspace`	—
`logspace`	—
`lu`	—
`magic`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30.
`max`	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`min`	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`ndgrid`	—
`ndims`	—
`nnz`	—
`nonzeros`	—
`norm`	—
`normest`	—
`numel`	—
`ones`	• Dimensions must be real, nonnegative integers. • The input `optimfun` must be a function supported for code generation.
`pascal`	—

Function	Remarks and Limitations
`permute`	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`pinv`	—
`planerot`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`prod`	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`qr`	—
`rand`	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `rand` method for other classes. For example, `rand(sz,'myclass')` does not invoke `myclass.rand(sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`randi`	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `randi` method for other classes. For example, `randi(imax,sz,'myclass')` does not invoke `myclass.randi(imax,sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`randn`	• The data type (class) must be a built-in MATLAB numeric type. Does not invoke the static `randn` method for other classes. For example, `randn(sz,'myclass')` does not invoke `myclass.randn(sz)`. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`randperm`	—

Function	Remarks and Limitations
`rank`	—
`rcond`	—
`repmat`	Size arguments must have a fixed size.
`reshape`	• If the input is a compile-time empty cell array, then the size arguments must be constants. • Size arguments must have a fixed size. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

`rng`	• Supports only the `'twister'`, `'v5normal'`, and `'v4'` generators.
	• Does not support the `'shuffle'` input.
	• For a MEX target:
	  • If extrinsic calls are disabled or `rng` is called inside a `parfor` loop, the output of `rng` in the MEX function is not compatible with the `rng` function in MATLAB. You cannot pass the output of `s = rng` from the MEX function to `rng` in MATLAB.
	  • If extrinsic calls are enabled and `rng` is not called from inside a `parfor` loop, only `rng` can access the data in the structure that `rng` returns.

`rosser`	—
`rot90`	Does not support cell arrays for the first argument.
`shiftdim`	• Does not support cell arrays for the first argument. • Second argument must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`sign`	—
`size`	—

Function	Remarks and Limitations
`sort`	• Does not support cell arrays for the first argument. • If the input is a complex type, `sort` orders the output according to absolute value. When `x` is a complex type that has all zero imaginary parts, use `sort(real(x))` to compute the sort order for real types. See "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`sortrows`	• Does not support cell arrays for the first argument. • If the input is a complex type, `sortrows` orders the output according to absolute value. When `x` is a complex type that has all zero imaginary parts, use `sortrows(real(x))` to compute the sort order for real types. See "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`squeeze`	Does not support cell arrays.
`sub2ind`	• The first argument must be a valid size vector. Size vectors for arrays with more than `intmax` elements are not supported. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`subspace`	—
`sum`	• If specified, `dim` must be a constant. • The `outtype` and `nanflag` options must be constant strings. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`toeplitz`	—
`trace`	—
`tril`	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
`triu`	• If supplied, the argument representing the order of the diagonal matrix must be a real and scalar integer value.
`true`	• Dimensions must be real, nonnegative, integers.
`vander`	—
`wilkinson`	`n` must be a fixed-size scalar.

Function	Remarks and Limitations
`zeros`	• Dimensions must be real, nonnegative, integers.

Neural Network Toolbox

You can use `genFunction` in the Neural Network Toolbox™ to generate a standalone MATLAB function for a trained neural network. You can generate C/C++ code from this standalone MATLAB function. To generate Simulink blocks, use the`genSim` function. See "Deploy Neural Network Functions".

Numerical Integration and Differentiation in MATLAB

Function	Remarks and Limitations
`cumtrapz`	—
`del2`	—
`diff`	• If supplied, the arguments representing the number of times to apply `diff` and the dimension along which to calculate the difference must be constants.
`gradient`	—
`ode23`	• All `odeset` option arguments must be constant. • Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function . • You must provide at least the two output arguments `T` and `Y`. • Input types must be homogeneous—all double or all single. • Variable-sizing support must be enabled. Requires dynamic memory allocation when `tspan` has two elements or you use event functions.
`ode45`	• All `odeset` option arguments must be constant. • Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function . • You must provide at least the two output arguments `T` and `Y`. • Input types must be homogeneous—all double or all single. • Variable-sizing support must be enabled. Requires dynamic memory allocation when `tspan` has two elements or you use event functions.

Function	Remarks and Limitations
`odeget`	The `name` argument must be constant.
`odeset`	All inputs must be constant.
`quad2d`	• Generates a warning if the size of the internal storage arrays is not large enough. If a warning occurs, a possible workaround is to divide the region of integration into pieces and sum the integrals over each piece.
`quadgk`	—
`trapz`	• If supplied, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Optimization Functions in MATLAB

Function	Remarks and Limitations
`fminsearch`	• Ignores the `Display` option. Does not print status information during execution. Test the `exitflag` output for the exit condition. • The output structure does not include the `algorithm` or `message` fields. • Ignores the `OutputFcn` and `PlotFcns` options.
`fzero`	• The first argument must be a function handle. Does not support structure, inline function, or string inputs for the first argument. • Supports up to three output arguments. Does not support the fourth output argument (the `output` structure).
`optimget`	Input parameter names must be constant.
`optimset`	• Does not support the syntax that has no input or output arguments: `optimset` • Functions specified in the options must be supported for code generation. • The fields of the options structure `oldopts` must be fixed-size fields. • For code generation, optimization functions ignore the `Display` option. • Does not support the additional options in an options structure created by the Optimization Toolbox `optimset` function. If an input options

Function	Remarks and Limitations
	structure includes the additional Optimization Toolbox options, the output structure does not include them.

Phased Array System Toolbox

C and C++ code generation for the following functions and System objects requires the Phased Array System Toolbox software.

Name	Remarks and Limitations
Antenna and Microphone Elements	
`aperture2gain`	Does not support variable-size inputs.
`azel2phithetapat`	Does not support variable-size inputs.
`azel2uvpat`	Does not support variable-size inputs.
`circpol2pol`	Does not support variable-size inputs.
`gain2aperture`	Does not support variable-size inputs.
phased.CosineAntennaElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
phased.CrossedDipoleAntennaElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
phased.CustomAntennaElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
phased.CustomMicrophoneElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.

Name	Remarks and Limitations
	• See “System Objects in MATLAB Code Generation”.
phased.IsotropicAntennaElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
phased.OmnidirectionalMicrophoneElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
phased.ShortDipoleAntennaElement	• `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported. • See “System Objects in MATLAB Code Generation”.
`phitheta2azelpat`	Does not support variable-size inputs.
`phitheta2uvpat`	Does not support variable-size inputs.
`pol2circpol`	Does not support variable-size inputs.
`polellip`	Does not support variable-size inputs.
`polloss`	Does not support variable-size inputs.
`polratio`	Does not support variable-size inputs.
`polsignature`	• Does not support variable-size inputs. • Supported only when output arguments are specified.
`stokes`	• Does not support variable-size inputs. • Supported only when output arguments are specified.
`uv2azelpat`	Does not support variable-size inputs.
`uv2phithetapat`	Does not support variable-size inputs.

Name	Remarks and Limitations
Array Geometries and Analysis	
`az2broadside`	Does not support variable-size inputs.
`broadside2az`	Does not support variable-size inputs.
`pilotcalib`	Does not support variable-size inputs.
phased.ArrayGain	• Does not support arrays containing polarized antenna elements, that is, the `phased.ShortDipoleAntennaElement` or `phased.CrossedDipoleAntennaElement` antennas. • See "System Objects in MATLAB Code Generation".
phased.ArrayResponse	See "System Objects in MATLAB Code Generation".
phased.ConformalArray	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
phased.ElementDelay	See "System Objects in MATLAB Code Generation".
phased.PartitionedArray	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
phased.ReplicatedSubarray	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
phased.SteeringVector	See "System Objects in MATLAB Code Generation".

Name	Remarks and Limitations
phased.UCA	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
phased.ULA	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
phased.URA	• `pattern`, `patternAzimuth`, `patternElevation`, `plotResponse`, and `viewArray` methods are not supported. • See "System Objects in MATLAB Code Generation".
Signal Radiation and Collection	
phased.Collector	See "System Objects in MATLAB Code Generation".
phased.Radiator	See "System Objects in MATLAB Code Generation".
phased.WidebandCollector	• Requires dynamic memory allocation. See "Limitations for System Objects that Require Dynamic Memory Allocation". • See "System Objects in MATLAB Code Generation".
phased.WidebandRadiator	See "System Objects in MATLAB Code Generation".
`sensorsig`	Does not support variable-size inputs.
Transmitters and Receivers	
`delayseq`	Does not support variable-size inputs.
`noisepow`	Does not support variable-size inputs.

Name	Remarks and Limitations
phased.ReceiverPreamp	See “System Objects in MATLAB Code Generation”.
phased.Transmitter	See “System Objects in MATLAB Code Generation”.
`systemp`	Does not support variable-size inputs.
Waveform Design and Analysis	
`ambgfun`	Does not support variable-size inputs.
phased.FMCWWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”. .
phased.LinearFMWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”.
phased.MFSKWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”.
phased.PhaseCodedWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”.
phased.RectangularWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”.
phased.SteppedFMWaveform	• `plot` method is not supported. • See “System Objects in MATLAB Code Generation”.
`range2bw`	Does not support variable-size inputs.
`range2time`	Does not support variable-size inputs.
`time2range`	Does not support variable-size inputs.
`unigrid`	Does not support variable-size inputs.

Name	Remarks and Limitations
Beamforming	
`cbfweights`	Does not support variable-size inputs.
`lcmvweights`	Does not support variable-size inputs.
`mvdrweights`	Does not support variable-size inputs.
phased.FrostBeamformer	• Requires dynamic memory allocation. See "Limitations for System Objects that Require Dynamic Memory Allocation". • See "System Objects in MATLAB Code Generation".
phased.LCMVBeamformer	See "System Objects in MATLAB Code Generation".
phased.MVDRBeamformer	See "System Objects in MATLAB Code Generation".
phased.PhaseShiftBeamformer	See "System Objects in MATLAB Code Generation".
phased.SteeringVector	See "System Objects in MATLAB Code Generation".
phased.SubbandMVDRBeamformer	See "System Objects in MATLAB Code Generation".
phased.SubbandPhaseShiftBeamformer	See "System Objects in MATLAB Code Generation".
phased.TimeDelayBeamformer	• Requires dynamic memory allocation. See "Limitations for System Objects that Require Dynamic Memory Allocation". • See "System Objects in MATLAB Code Generation".
phased.TimeDelayLCMVBeamformer	• Requires dynamic memory allocation. See "Limitations for System Objects that Require Dynamic Memory Allocation". • See "System Objects in MATLAB Code Generation".
`sensorcov`	Does not support variable-size inputs.

Name	Remarks and Limitations
`steervec`	Does not support variable-size inputs.
Direction of Arrival (DOA) Estimation	
`aictest`	Does not support variable-size inputs.
`espritdoa`	Does not support variable-size inputs.
`gccphat`	Does not support variable-size inputs.
`mdltest`	Does not support variable-size inputs.
phased.BeamscanEstimator	See “System Objects in MATLAB Code Generation”.
phased.BeamscanEstimator2D	See “System Objects in MATLAB Code Generation”.
phased.BeamspaceESPRITEstimator	See “System Objects in MATLAB Code Generation”.
phased.ESPRITEstimator	See “System Objects in MATLAB Code Generation”.
phased.GCCEstimator	See “System Objects in MATLAB Code Generation”.
phased.MVDREstimator	See “System Objects in MATLAB Code Generation”.
phased.MVDREstimator2D	See “System Objects in MATLAB Code Generation”.
phased.RootMUSICEstimator	See “System Objects in MATLAB Code Generation”.
phased.RootWSFEstimator	See “System Objects in MATLAB Code Generation”.
phased.SumDifferenceMonopulseTracker	See “System Objects in MATLAB Code Generation”.
phased.SumDifferenceMonopulseTracker2D	See “System Objects in MATLAB Code Generation”.
`rootmusicdoa`	Does not support variable-size inputs.
`spsmooth`	Does not support variable-size inputs.
Space-Time Adaptive Processing (STAP)	

Name	Remarks and Limitations
`dopsteeringvec`	Does not support variable-size inputs.
phased.ADPCACanceller	See “System Objects in MATLAB Code Generation”.
phased.AngleDopplerResponse	See “System Objects in MATLAB Code Generation”.
phased.DPCACanceller	See “System Objects in MATLAB Code Generation”.
phased.STAPSMIBeamformer	See “System Objects in MATLAB Code Generation”.
`val2ind`	Does not support variable-size inputs.
Targets, Interference, and Signal Propagation	
`billingsleyicm`	Does not support variable-size inputs.
`depressionang`	Does not support variable-size inputs.
`effearthradius`	Does not support variable-size inputs.
`fspl`	Does not support variable-size inputs.
`fogpl`	Does not support variable-size inputs.
`gaspl`	Does not support variable-size inputs.
`grazingang`	Does not support variable-size inputs.
`horizonrange`	Does not support variable-size inputs.
phased.BackscatterRadarTarget	See “System Objects in MATLAB Code Generation”
phased.BarrageJammer	See “System Objects in MATLAB Code Generation”.
phased.ConstantGammaClutter	See “System Objects in MATLAB Code Generation”.
phased.FreeSpace	• Requires dynamic memory allocation. See “Limitations for System Objects that Require Dynamic Memory Allocation”. • See “System Objects in MATLAB Code Generation”.

Name	Remarks and Limitations
phased.LOSChannel	See “System Objects in MATLAB Code Generation”
phased.RadarTarget	See “System Objects in MATLAB Code Generation”.
phased.TwoRayChannel	See “System Objects in MATLAB Code Generation”.
phased.WidebandFreeSpace	See “System Objects in MATLAB Code Generation”.
phased.WidebandLOSChannel	See “System Objects in MATLAB Code Generation”
`physconst`	Does not support variable-size inputs.
`surfacegamma`	Does not support variable-size inputs.
`surfclutterrcs`	Does not support variable-size inputs.
`rainpl`	Does not support variable-size inputs.
Motion Modeling and Coordinate Systems	
`azel2phitheta`	Does not support variable-size inputs.
`azel2uv`	Does not support variable-size inputs.
`azelaxes`	Does not support variable-size inputs.
`cart2sphvec`	Does not support variable-size inputs.
`dop2speed`	Does not support variable-size inputs.
`global2localcoord`	Does not support variable-size inputs.
`local2globalcoord`	Does not support variable-size inputs.
phased.Platform	See “System Objects in MATLAB Code Generation”.
`phitheta2azel`	Does not support variable-size inputs.
`phitheta2uv`	Does not support variable-size inputs.
`radialspeed`	Does not support variable-size inputs.
`rangeangle`	Does not support variable-size inputs.
`rotx`	Does not support variable-size inputs.

Name	Remarks and Limitations
`roty`	Does not support variable-size inputs
`rotz`	Does not support variable-size inputs.
`speed2dop`	Does not support variable-size inputs.
`sph2cartvec`	Does not support variable-size inputs.
`uv2azel`	Does not support variable-size inputs.

Polynomials in MATLAB

Function	Remarks and Limitations
`poly`	• Does not discard nonfinite input values • Complex input produces complex output • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`polyder`	The output can contain fewer `NaN`s than the MATLAB output. However, if the input contains a `NaN`, the output contains at least one `NaN`.
`polyfit`	"Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`polyint`	—
`polyval`	—
`polyvalm`	—
`roots`	• Output is variable size. • Output is complex. • Roots are not always in the same order as MATLAB. • Roots of poorly conditioned polynomials do not always match MATLAB.

Programming Utilities in MATLAB

Function	Remarks and Limitations
`mfilename`	—

Relational Operators in MATLAB

Function	Remarks and Limitations
`eq`	—
`ge`	—
`gt`	—
`le`	—
`lt`	—
`ne`	—

Robotics System Toolbox

C/C++ code generation for the following functions requires the Robotics System Toolbox software.

Name	Remarks and Limitations
Algorithm Design	
robotics.PurePursuit	Supports MATLAB Function block: No
robotics.VectorFieldHistogram	Supports MATLAB Function block: No
robotics.ParticleFilter	Supports MATLAB Function block: No
Coordinate System Transformations	
`angdiff`	Supports MATLAB Function block: Yes
`axang2quat`	Supports MATLAB Function block: Yes
`axang2rotm`	Supports MATLAB Function block: Yes
`axang2tform`	Supports MATLAB Function block: Yes
`cart2hom`	Supports MATLAB Function block: Yes
`eul2quat`	Supports MATLAB Function block: Yes
`eul2rotm`	Supports MATLAB Function block: Yes
`eul2tform`	Supports MATLAB Function block: Yes
`hom2cart`	Supports MATLAB Function block: Yes
`quat2axang`	Supports MATLAB Function block: Yes

Name	Remarks and Limitations
`quat2eul`	Supports MATLAB Function block: Yes
`quat2rotm`	Supports MATLAB Function block: Yes
`quat2tform`	Supports MATLAB Function block: Yes
`rotm2axang`	Supports MATLAB Function block: Yes
`rotm2eul`	Supports MATLAB Function block: Yes
`rotm2quat`	Supports MATLAB Function block: Yes
`rotm2tform`	Supports MATLAB Function block: Yes
`tform2axang`	Supports MATLAB Function block: Yes
`tform2eul`	Supports MATLAB Function block: Yes
`tform2quat`	Supports MATLAB Function block: Yes
`tform2rotm`	Supports MATLAB Function block: Yes
`tform2trvec`	Supports MATLAB Function block: Yes
`trvec2tform`	Supports MATLAB Function block: Yes

Rounding and Remainder Functions in MATLAB

Function	Remarks and Limitations
`ceil`	—
`fix`	—
`floor`	—
`mod`	• Performs the arithmetic using the output class. Results might not match MATLAB due to differences in rounding errors. If one of the inputs has type `int64` or `uint64`, then both inputs must have the same type.
`rem`	• Performs the arithmetic using the output class. Results might not match MATLAB due to differences in rounding errors. • If one of the inputs has type `int64` or `uint64`, then both inputs must have the same type.
`round`	Supports only the syntax `Y = round(X)`.

Set Operations in MATLAB

Function	Remarks and Limitations

`intersect`	• Does not support cell arrays for the first or second arguments.
	• When you do not specify the `'rows'` option:
	  • Inputs `A` and `B` must be vectors. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
	  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
	  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
	  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
	• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
	• When the `setOrder` is `'sorted'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
	• Complex inputs must be `single` or `double`.
	• When one input is complex and the other input is real, do one of the following:
	  • Set `setOrder` to `'stable'`.
	  • Sort the real input in complex ascending order (by absolute value). Suppose the real input is `x`. Use `sort(complex(x))`or `sortrows(complex(x))`.
	• "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

`ismember`	• Does not support cell arrays for the first or second arguments. • Complex inputs must be `single` or `double`. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

Function	Remarks and Limitations
`issorted`	• Does not support cell arrays for the first argument. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30. • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

`setdiff`	• Does not support cell arrays for the first or second arguments.
	• When you do not specify the `'rows'` option:
	  • Inputs `A` and `B` must be vectors. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
	  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
	  • Do not use `[]` to represent the empty set. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
	  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
	• When you specify both the `'legacy'` and `'rows'` options, the output `ia` is a column vector. If `ia` is empty, it is 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
	• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
	• Complex inputs must be `single` or `double`.
	• When one input is complex and the other input is real, do one of the following:
	  • Set `setOrder` to `'stable'`.
	  • Sort the real input in complex ascending order (by absolute value). Suppose the real input is `x`. Use `sort(complex(x))`or `sortrows(complex(x))`.
	• "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

Function	Remarks and Limitations

`setxor`	• Does not support cell arrays for the first or second arguments.
	• When you do not specify the `'rows'` option:
	  • Inputs `A` and `B` must be vectors with the same orientation. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
	  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
	  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example , `zeros(1,0)`, to represent the empty set.
	  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
	• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
	• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` flag, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
	• Complex inputs must be `single` or `double`.
	• When one input is complex and the other input is real, do one of the following:
	  • Set `setOrder` to `'stable'`.
	  • Sort the real input in complex ascending order (by absolute value). Suppose the real input is `x`. Use `sort(complex(x))`or `sortrows(complex(x))`.
	• “Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 47-4.

Function	Remarks and Limitations

`union`	• Does not support cell arrays for the first or second arguments.
	• When you do not specify the `'rows'` option:
	  • Inputs `A` and `B` must be vectors with the same orientation. If you specify the `'legacy'` option, inputs `A` and `B` must be row vectors.
	  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
	  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example , `zeros(1,0)`, to represent the empty set.
	  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
	• When you specify both the `'legacy'` option and the `'rows'` option, the outputs `ia` and `ib` are column vectors. If these outputs are empty, they are 0-by-1, never 0-by-0, even if the output `C` is 0-by-0.
	• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the inputs must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
	• Complex inputs must be `single` or `double`.
	• When one input is complex and the other input is real, do one of the following:
	  • Set `setOrder` to `'stable'`.
	  • Sort the real input in complex ascending order (by absolute value). Suppose the real input is `x`. Use `sort(complex(x))`or `sortrows(complex(x))`.
	• "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.

Function	Remarks and Limitations

`unique`	• Does not support cell arrays for the first argument.
	• When you do not specify the `'rows'` option:
	  • The input `A` must be a vector. If you specify the `'legacy'` option, the input `A` must be a row vector.
	  • The first dimension of a variable-size row vector must have fixed length 1. The second dimension of a variable-size column vector must have fixed length 1.
	  • The input `[]` is not supported. Use a 1-by-0 or 0-by-1 input, for example, `zeros(1,0)`, to represent the empty set.
	  • If you specify the `'legacy'` option, empty outputs are row vectors, 1-by-0, never 0-by-0.
	• When you specify both the `'rows'` option and the `'legacy'`option, outputs `ia` and `ic` are column vectors. If these outputs are empty, they are 0-by-1, even if the output `C` is 0-by-0.
	• When the `setOrder` is not `'stable'` or when you specify the `'legacy'` option, the input `A` must already be sorted in ascending order. The first output, `C`, is sorted in ascending order.
	• Complex inputs must be `single` or `double`.

Signal Processing in MATLAB

Function	Remarks and Limitations
`chol`	—
`conv`	—
`fft`	• "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`fft2`	—
`fftn`	The `siz` argument must have a fixed size.
`fftshift`	—
`filter`	• If supplied, `dim` must be a constant. • v

Function	Remarks and Limitations
`freqspace`	—
`ifft`	• Output is complex. • Does not support the `'symmetric'` option. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`ifft2`	Does not support the `'symmetric'` option.
`ifftn`	• Does not support the `'symmetric'` option. • The `siz` argument must have a fixed size.
`ifftshift`	—
`svd`	Uses a different `SVD` implementation than MATLAB. Because the singular value decomposition is not unique, left and right singular vectors might differ from those computed by MATLAB.
`zp2tf`	—

Signal Processing Toolbox

C and C++ code generation for the following functions requires the Signal Processing Toolbox software. These functions do not support variable-size inputs, you must define the size and type of the function inputs. For more information, see "Specifying Inputs in Code Generation from MATLAB ".

Note: Many Signal Processing Toolbox functions require constant inputs in generated code. To specify a constant input for `codegen`, use coder.Constant.

Function	Remarks/Limitations
`barthannwin`	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`bartlett`	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`besselap`	Filter order must be a constant. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
`bitrevorder`	—
`blackman`	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`blackmanharris`	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`bohmanwin`	Window length must be a constant. Expressions or variables are allowed if their values do not change.
`buttap`	Filter order must be a constant. Expressions or variables are allowed if their values do not change.
`butter`	Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.
`buttord`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cfirpm`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb1ap`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb2ap`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb1ord`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheb2ord`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`chebwin`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheby1`	All Inputs must be constants. Expressions or variables are allowed if their values do not change.
`cheby2`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`db2pow`	—

Function	Remarks/Limitations
`dct`	C and C++ code generation for `dct` requires DSP System Toolbox software. Length of transform dimension must be a power of two. If specified, the pad or truncation value must be constant. Expressions or variables are allowed if their values do not change.
`downsample`	—
`dpss`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`ellip`	Inputs must be constant. Expressions or variables are allowed if their values do not change.
`ellipap`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`ellipord`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`filtfilt`	Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.
`findpeaks`	—
`fir1`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fir2`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fircls`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`fircls1`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firls`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firpm`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`firpmord`	All inputs must be constants. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
`flattopwin`	All inputs must be constants. Expressions or variables are allowed if their values do not change.
`freqz`	• Does not support variable-size inputs. • When called with no output arguments, and without a semicolon at the end, `freqz` returns the complex frequency response of the input filter, evaluated at 512 points. If the semicolon is added, the function produces a plot of the magnitude and phase response of the filter. See “freqz With No Output Arguments”.
`gausswin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`hamming`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`hann`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`idct`	C and C++ code generation for `idct` requires DSP System Toolbox software. Length of transform dimension must be a power of two. If specified, the pad or truncation value must be constant. Expressions or variables are allowed if their values do not change.
`intfilt`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`kaiser`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`kaiserord`	—
`levinson`	C and C++ code generation for `levinson` requires DSP System Toolbox software. If specified, the order of recursion must be a constant. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
`maxflat`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`nuttallwin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`parzenwin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`peak2peak`	—
`peak2rms`	—
`pow2db`	—
`rcosdesign`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`rectwin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`resample`	C and C++ code generation for `resample` requires DSP System Toolbox software. The upsampling and downsampling factors must be specified as constants. Expressions or variables are allowed if their values do not change.
`rms`	—
`sgolay`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`sosfilt`	—
`taylorwin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`triang`	All inputs must be constant. Expressions or variables are allowed if their values do not change.
`tukeywin`	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
`upfirdn`	C and C++ code generation for `upfirdn` requires DSP System Toolbox software. Filter coefficients, upsampling factor, and downsampling factor must be constants. Expressions or variables are allowed if their values do not change. Variable-size inputs are not supported.
`upsample`	Either declare input `n` as constant, or use the `assert` function in the calling function to set upper bounds for `n`. For example, `assert(n<10)`
`xcorr`	Leading ones in `size(x)` must be constant for every input `x`. If `x` is variable-size and is a row vector, it must be 1-by-`:`. It cannot be `:`-by-`:` with `size(x,1)` = 1 at run time.
`yulewalk`	If specified, the order of recursion must be a constant. Expressions or variables are allowed if their values do not change.

Special Values in MATLAB

Function	Remarks and Limitations
`eps`	• Supported for scalar fixed-point signals only. • Supported for scalar, vector, and matrix, `fi` single and `fi` double signals.
`inf`	• Dimensions must be real, nonnegative, integers.
`intmax`	—
`intmin`	—
NaN or `nan`	• Dimensions must be real, nonnegative, integers.
`pi`	—
`realmax`	—
`realmin`	—

Specialized Math in MATLAB

Function	Remarks and Limitations
`airy`	Always returns a complex result.
`besseli`	• If the order `nu` is less than `0`, it must be an integer. • Always returns a complex result.
`besselj`	• If the order `nu` is less than `0`, it must be an integer. • Always returns a complex result.
`beta`	—
`betainc`	Always returns a complex result.
`betaincinv`	Always returns a complex result.
`betaln`	—
`ellipke`	—
`erf`	—
`erfc`	—
`erfcinv`	—
`erfcx`	—
`erfinv`	—
`expint`	—
`gamma`	—
`gammainc`	Output is always complex.
`gammaincinv`	Output is always complex.
`gammaln`	—
`psi`	—

Statistics in MATLAB

Function	Remarks and Limitations
`corrcoef`	• Row-vector input is only supported when the first two inputs are vectors and nonscalar.
`cummin`	—

Function	Remarks and Limitations
`cummax`	—
`mean`	• If specified, `dim` must be a constant. • The `outtype` and `nanflag` options must be constant strings. • Does not support the `'native'` output data type option for integer types. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`median`	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30 • "Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4.
`mode`	• Does not support third output argument `C` (cell array). • If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`std`	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30
`var`	• If specified, `dim` must be a constant. • "Variable-Sizing Restrictions for Code Generation of Toolbox Functions" on page 48-30

Statistics and Machine Learning Toolbox

C and C++ code generation for the following functions requires the Statistics and Machine Learning Toolbox software.

Function	Remarks and Limitations
`betacdf`	—
`betafit`	—
`betainv`	—

Function	Remarks and Limitations
`betalike`	—
`betapdf`	—
`betarnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`betastat`	—
`binocdf`	—
`binoinv`	—
`binopdf`	—
`binornd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`binostat`	—
`cdf`	—
`chi2cdf`	—
`chi2inv`	—
`chi2pdf`	—
`chi2rnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`chi2stat`	—
`evcdf`	—
`evinv`	—
`evpdf`	—

Function	Remarks and Limitations
`evrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`evstat`	—
`expcdf`	—
`expinv`	—
`exppdf`	—
`exprnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`expstat`	—
`fcdf`	—
`finv`	—
`fpdf`	—
`frnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`fstat`	—
`gamcdf`	—
`gaminv`	—
`gampdf`	—
`gamrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.

Function	Remarks and Limitations
`gamstat`	—
`geocdf`	—
`geoinv`	—
`geomean`	—
`geopdf`	—
`geornd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`geostat`	—
`gevcdf`	—
`gevinv`	—
`gevpdf`	—
`gevrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`gevstat`	—
`gpcdf`	—
`gpinv`	—
`gppdf`	—
`gprnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`gpstat`	—
`harmmean`	—
`hygecdf`	—

Function	Remarks and Limitations
`hygeinv`	—
`hygepdf`	—
`hygernd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`hygestat`	—
`icdf`	—
`iqr`	—
`kmeans`	• If the `Start` method uses random selections, the initial centroid cluster positions might not match MATLAB. • If the number of rows in `X` is fixed, does not remove rows of `X` that contain a `NaN`. • The cluster centroid locations in `C` can have a different order than in MATLAB. In this case, the cluster indices in `idx` have corresponding differences. • If you provide `Display`, its value must be `'off'`. • If you provide `Streams`, it must be empty and `UseSubstreams` must be `false`. • When you set the `UseParallel` option to `true`, some computations can execute in parallel even when `Replicates` is `1`. For large data sets, when `Replicates` is `1`, consider setting the `UseParallel` option to `true`.
`kurtosis`	—
`logncdf`	—
`logninv`	—
`lognpdf`	—

Function	Remarks and Limitations
`lognrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`lognstat`	—
`mad`	Input `dim` cannot be empty.
`mnpdf`	Input `dim` cannot be empty.
`moment`	If `order` is nonintegral and `X` is real, use `moment(complex(X), order)`.
`nancov`	If the input is variable-size and is `[]` at run time, returns `[]` not `NaN`.
`nanmax`	—
`nanmean`	—
`nanmedian`	—
`nanmin`	—
`nanstd`	—
`nansum`	—
`nanvar`	—
`nbincdf`	—
`nbininv`	—
`nbinpdf`	—
`nbinrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`nbinstat`	—
`ncfcdf`	—
`ncfinv`	—
`ncfpdf`	—

Function	Remarks and Limitations
`ncfrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`ncfstat`	—
`nctcdf`	—
`nctinv`	—
`nctpdf`	—
`nctrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`nctstat`	—
`ncx2cdf`	—
`ncx2rnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`ncx2stat`	—
`normcdf`	—
`norminv`	—
`normpdf`	—
`normrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`normstat`	—

Function	Remarks and Limitations
`pca`	• Ignores the `'Display'` value for `'Options'` when `'Algorithm'` is `'als'`. • If supplied, `'Weights'` and `'VariableWeights'` must be real. • Always returns the fifth output `explained` as a column vector. • Always returns the sixth output `mu` as a row vector. • If `mu` is empty, `pca` returns `mu` as a 1-by-0 array. `pca` does not convert `mu` to a 0-by-0 empty array. • Does not treat an input matrix `X` that has all NaN values as a special case. The outputs have the sizes that they have when some of the inputs are finite.
`pdf`	—
`pearsrnd`	Matches MATLAB only when generated output `r` is scalar.
`poisscdf`	—
`poissinv`	—
`poisspdf`	—
`poissrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`poisstat`	—

Function	Remarks and Limitations

`prctile`	• "Automatic dimension restriction"
	• If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
	  • You do not supply the `dim` input.
	  • `X` is a variable-size array.
	  • `X` is not a variable-length vector.
	  • `X` is a vector at run time.
	  • The orientation of the vector `X` does not match the orientation of the vector `p`.
	  In this case, the output `Y` matches the orientation of `X` not the orientation of `p`.

`quantile`	—
`randg`	—
`random`	—
`randsample`	When sampling without replacement, the order of the output values might not match MATLAB.
`raylcdf`	—
`raylinv`	—
`raylpdf`	—
`raylrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`raylstat`	—
`skewness`	—
`tcdf`	—
`tinv`	—
`tpdf`	—

Function	Remarks and Limitations
`trnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`tstat`	—
`unidcdf`	—
`unidinv`	—
`unidpdf`	—
`unidrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`unidstat`	—
`unifcdf`	—
`unifinv`	—
`unifpdf`	—
`unifrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.
`unifstat`	—
`wblcdf`	—
`wblinv`	—
`wblpdf`	—
`wblrnd`	Can return a different sequence of numbers than MATLAB if either of the following is true: • The output is nonscalar. • An input parameter is invalid for the distribution.

Function	Remarks and Limitations
`wblstat`	—
`zscore`	—

String Functions in MATLAB

Function	Remarks and Limitations
`bin2dec`	• Does not support cell arrays. • Does not match MATLAB when the input is empty.
`blanks`	—
`char`	Does not support cell arrays.
`deblank`	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.
`dec2bin`	• If input `d` is `double`, `d` must be less than `2^52`. • If input `d` is `single`, `d` must be less than `2^23`. • Unless you specify input `n` to be constant and `n` is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, `n` must be at least `52` for `double`, `23` for `single`, `16` for `char`, `32` for `int32`, `16` for `int16`, and so on.
`dec2hex`	• If input `d` is `double`, `d` must be less than `2^52`. • If input `d` is `single`, `d` must be less than `2^23`. • Unless you specify input `n` to be constant, and `n` is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, `n` must be at least `13` for `double`, `6` for `single`, `4` for `char`, `8` for `int32`, `4` for `int16`, and so on.
`hex2dec`	Does not support cell arrays.
`hex2num`	• Does not support cell arrays. • For `n = hex2num(S)`, `size(S,2) <= length(num2hex(0))`
`iscellstr`	—
`ischar`	—

Function	Remarks and Limitations
`isletter`	• Input values from the `char` class must be in the range 0-127.
`isspace`	• Input values from the `char` class must be in the range 0–127.
`isstrprop`	• Supports only inputs from `char` and `integer` classes. • Input values must be in the range 0-127.
`lower`	• Supports only `char` inputs. Does not support cell arrays. • Input values must be in the range 0-127.
`num2hex`	—
`str2double`	• Does not support cell arrays. • Always returns a complex result.
`strcmp`	• Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.
`strcmpi`	• Does not support enumeration inputs. • Input values from the `char` class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.
`strfind`	• Does not support cell arrays. • If `pattern` does not exist in `str`, returns `zeros(1,0)` not `[]`. To check for an empty return, use `isempty`. • Inputs must be character row vectors.
`strjoin`	Always returns a string that has size 1-by-n. For empty inputs, returns a 1-by-0 string not `[]`.
`strjust`	Does not support a cell array of strings for the first argument.
`strncmp`	• Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.

Function	Remarks and Limitations
`strncmpi`	• Does not support enumeration inputs. • Input values from the `char` class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.
`strrep`	• Does not support cell arrays. • If `oldSubstr` does not exist in `origStr`, returns `blanks(0)`. To check for an empty return, use `isempty`. • Inputs must be character row vectors.
`strtok`	Does not support a cell arrays for the first argument.
`strtrim`	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.
`upper`	• Supports only inputs from the `char` class. Does not support cell arrays. • Input values must be in the range 0-127.

System Identification Toolbox

C and C++ code generation for the following functions and System objects requires the System Identification Toolbox software.

Name	Remarks and Limitations
`recursiveAR`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see “Generate Code for Online Parameter Estimation in MATLAB”.
`recursiveARMA`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see “Generate Code for Online Parameter Estimation in MATLAB”.

Name	Remarks and Limitations
`recursiveARMAX`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveARX`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveBJ`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveLS`	• For Simulink-based workflows, use `Recursive Least Squares Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".
`recursiveOE`	• For Simulink-based workflows, use `Recursive Polynomial Model Estimator`. • For limitations, see "Generate Code for Online Parameter Estimation in MATLAB".

Trigonometry in MATLAB

Function	Remarks and Limitations
`acos`	When the input value `x` is real, but the output should be complex, generates an error during simulation and returns `NaN` in generated code. To get the complex result, make the input value complex by passing in `complex(x)`.
`acosd`	—
`acosh`	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`acot`	—
`acotd`	—
`acoth`	—
`acsc`	—
`acscd`	—
`acsch`	—
`asec`	—
`asecd`	—
`asech`	—
`asin`	• Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`asind`	—
`asinh`	—
`atan`	—
`atan2`	—
`atan2d`	—
`atand`	—

Function	Remarks and Limitations
`atanh`	Generates an error during simulation and returns `NaN` in generated code when the input value `x` is real, but the output should be complex. To get the complex result, make the input value complex by passing in `complex(x)`.
`cos`	—
`cosd`	—
`cosh`	—
`cot`	—
`cotd`	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`coth`	—
`csc`	—
`cscd`	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`csch`	—
`deg2rad`	—
`hypot`	—
`rad2deg`	—
`sec`	—
`secd`	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`sech`	—
`sin`	—
`sind`	—
`sinh`	—
`tan`	—
`tand`	• In some cases, returns `-Inf` when MATLAB returns `Inf`. • In some cases, returns `Inf` when MATLAB returns `-Inf`.
`tanh`	—

WLAN System Toolbox

C and C++ code generation for the following functions and System objects requires the WLAN System Toolbox software.

System Objects Supported for Code Generation

Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

Toolbox Name	See
Communications System Toolbox	"System Objects in MATLAB Code Generation" in the DSP System Toolbox documentation.
Computer Vision System Toolbox	"System Objects in MATLAB Code Generation" in the Computer Vision System Toolbox documentation.
DSP System Toolbox	"System Objects in MATLAB Code Generation" in the DSP System Toolbox documentation.
Image Acquisition Toolbox	• `imaq.VideoDevice`. • "Code Generation with VideoDevice System Object" in the Image Acquisition Toolbox documentation.
Phased Array System Toolbox	"Code Generation" in the Phased Array System Toolbox documentation.
System Identification Toolbox	"Generate Code for Online Parameter Estimation in MATLAB" in the System Identification Toolbox documentation.
WLAN System Toolbox	"System Objects in MATLAB Code Generation" in the DSP System Toolbox documentation.

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2 and "Functions and Objects Supported for C and C++ Code Generation — Category List" on page 44-164.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of

whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Object-Oriented Programming”.

Defining MATLAB Variables for C/C++ Code Generation

- "Variables Definition for Code Generation" on page 46-2
- "Best Practices for Defining Variables for C/C++ Code Generation" on page 46-3
- "Eliminate Redundant Copies of Variables in Generated Code" on page 46-7
- "Reassignment of Variable Properties" on page 46-9
- "Define and Initialize Persistent Variables" on page 46-10
- "Reuse the Same Variable with Different Properties" on page 46-11
- "Avoid Overflows in for-Loops" on page 46-15
- "Supported Variable Types" on page 46-17

Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
  x = 0;
else
  x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for *x*:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
  x = 0;
else
  x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 46-3.

Best Practices for Defining Variables for C/C++ Code Generation

In this section...
"Define Variables By Assignment Before Using Them" on page 46-3
"Use Caution When Reassigning Variables" on page 46-5
"Use Type Cast Operators in Variable Definitions" on page 46-5
"Define Matrices Before Assigning Indexed Variables" on page 46-6

Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

Assignment:	Defines:
`a = 14.7;`	`a` as a real double scalar.
`b = a;`	`b` with properties of `a` (real double scalar).
`c = zeros(5,2);`	`c` as a real 5-by-2 array of doubles.
`d = [1 2 3 4 5; 6 7 8 9 0];`	`d` as a real 5-by-2 array of doubles.
`y = int16(3);`	`y` as a real 16-bit integer scalar.

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation (see Defining a Variable for Multiple Execution Paths).

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly (see Defining Fields in a Structure).

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in "Eliminate Redundant Copies of Variables in Generated Code" on page 46-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see “Define and Initialize Persistent Variables” on page 46-10.

Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
  x = 11;
end
% Later in your code ...
if c > 0
  use(x);
end
...
```

Here, *x* is assigned only if `c > 0` and used only when `c > 0`. This code works in MATLAB, but generates a compilation error during code generation because it detects that *x* is undefined on some execution paths (when `c <= 0`),.

To make this code suitable for code generation, define *x* before using it:

```
x = 0;
...
if c > 0
  x = 11;
end
% Later in your code ...
if c > 0
  use(x);
end
...
```

Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
  s.a = 11;
  disp(s);
else
  s.a = 12;
```

```
  s.b = 12;
end
% Try to use s
use(s);
...
```

Here, the first part of the `if` statement uses only the field *a*, and the `else` clause uses fields *a* and *b*. This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see "Structure Definition for Code Generation" on page 49-2.

To make this code suitable for C/C++ code generation, define all fields of *s* before using it.

```
...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
  s.a = 11;
  disp(s);
else
  s.a = 12;
  s.b = 12;
end
% Use s
use(s);
...
```

Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in "Reassignment of Variable Properties" on page 46-9.

Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```
...
```

```
x = 15; % x is of type double by default.
y = uint8(x); % y has the value of x, but cast to uint8.
...
```

Define Matrices Before Assigning Indexed Variables

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g
               % OK for assigning value once created
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 48-27.

Eliminate Redundant Copies of Variables in Generated Code

In this section...

"When Redundant Copies Occur" on page 46-7

"How to Eliminate Redundant Copies by Defining Uninitialized Variables" on page 46-7

"Defining Uninitialized Variables" on page 46-8

When Redundant Copies Occur

During C/C++ code generation, MATLAB checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in "How to Eliminate Redundant Copies by Defining Uninitialized Variables" on page 46-7.

How to Eliminate Redundant Copies by Defining Uninitialized Variables

1. Define the variable with `coder.nullcopy`.
2. Initialize the variable before reading it.

   When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

   ### What happens if you access uninitialized data?

   Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines *X* to be a 1-by-5 vector of real doubles, but also initializes each element of *X* to zero.

```
function X = fcn %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
   if mod(i,2) == 0
      X(i) = i;
   else
      X(i) = 0;
   end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of *X*:

```
function X = fcn2 %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
   if mod(i,2) == 0
      X(i) = i;
   else
      X(i) = 0;
   end
end
```

Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

Dynamically sized variables

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

Variables reused in the code for different purposes

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 46-11.

Define and Initialize Persistent Variables

Persistent variables are local to the function in which they are defined, but they retain their values in memory between calls to the function. To define persistent variables for C/C++ code generation, use the `persistent` statement, as in this example:

```
persistent PROD_X;
```

The definition should appear at the top of the function body, after the header and comments, but before the first use of the variable. During code generation, the value of the persistent variable is initialized to an empty matrix by default. You can assign your own value after the definition by using the `isempty` statement, as in this example:

```
function findProduct(inputvalue) %#codegen
persistent PROD_X

if isempty(PROD_X)
   PROD_X = 1;
end
PROD_X = PROD_X * inputvalue;
end
```

Reuse the Same Variable with Different Properties

In this section...

"When You Can Reuse the Same Variable with Different Properties" on page 46-11
"When You Cannot Reuse Variables" on page 46-11
"Limitations of Variable Reuse" on page 46-14

When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if MATLAB can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report (see "MATLAB Code Variables in a Report" on page 39-50).

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable *t* in an `if` statement, where it holds a scalar double, then reuses *t* outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

To compile this example and see how MATLAB renames the reused variable *t*, see Variable Reuse in an if Statement.

When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to *x* in the `if` statement and reuses *x* to store a matrix of doubles in the `else` clause. It then uses *x*

after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable *x* can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
  if use_fixpoint
   % x is fixed-point
      x = fi(data, 1, 12, 3);
  else
    % x is a matrix of doubles
      x = data;
  end
  % When x is reused here, it is not possible to determine its
  % class, size, and complexity
  t = sum(sum(x));
  y = t > 0;
end
```

Variable Reuse in an if Statement

To see how MATLAB renames a reused variable *t*:

1. Create a MATLAB file `example1.m` containing the following code.

   ```
   function y = example1(u) %#codegen
   if all(all(u>0))
       % First, t is used to hold a scalar double value
       t = mean(mean(u)) / numel(u);
       u = u - t;
   end
   % t is reused to hold a vector of doubles
   t = find(u > 0);
   y = sum(u(t(2:end-1)));
   end
   ```

2. Compile `example1`.

   For example, to generate a MEX function, enter:

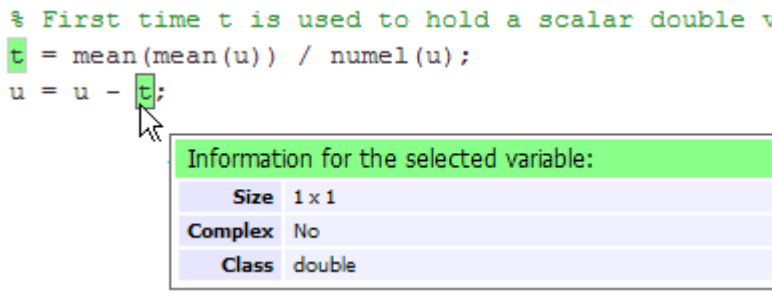
   ```
   codegen -o example1x -report example1.m -args {ones(5,5)}
   ```

   Note: `codegen` requires a MATLAB Coder license.

When the compilation is complete, `codegen` generates a MEX function, `example1x` in the current folder, and provides a link to the code generation report.

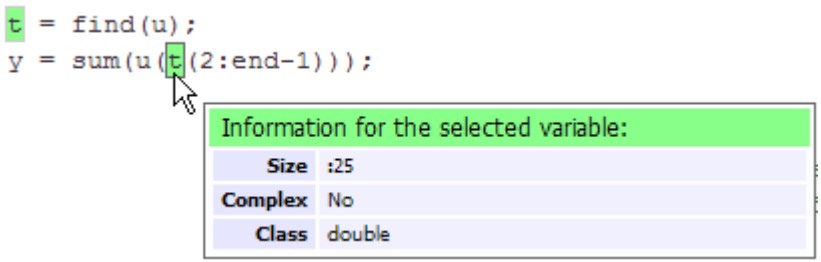
3. Open the code generation report.
4. In the MATLAB code pane of the code generation report, place your pointer over the variable *t* inside the `if` statement.

   The code generation report highlights both instances of *t* in the `if` statement because they share the same class, size, and complexity. It displays the data type information for *t* at this point in the code. Here, *t* is a scalar double.



5. In the MATLAB code pane of the report, place your pointer over the variable *t* outside the for-loop.

   This time, the report highlights both instances of *t* outside the `if` statement. The report indicates that *t* might hold up to `25` doubles. The size of *t* is `:25`, that is, a column vector containing a maximum of `25` doubles.



6. Click the **Variables** tab to view the list of variables used in `example1`.

The report displays a list of the variables in `example1`. There are two uniquely named local variables *t>1* and *t>2*.

7 In the list of variables, place your pointer over *t>1*.

The code generation report highlights both instances of *t* in the `if` statement.

8 In the list of variables, place your pointer over *t>2*

The code generation report highlights both instances of *t* outside the `if` statement.

Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.varsize`.
- Variables whose names are controlled using `coder.cstructname`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a `MATLAB Function` block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

Avoid Overflows in for-Loops

When memory integrity checks are enabled, if the code generation software detects that a loop variable might overflow on the last iteration of the `for`-loop, it reports an error.

To avoid this error, use the workarounds provided in the following table.

Loop conditions causing the error	Workaround

• The loop counter increments by 1
• The end value equals the maximum value of the integer type
• The loop is not covering the full range of the integer type
	Rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:
	`N=intmax('int16')`
	`for k=N-10:N`
	with:
	`for k=1:10`

• The loop counter decrements by 1
• The end value equals the minimum value of the integer type
• The loop is not covering the full range of the integer type
	Rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:
	`N=intmin('int32')`
	`for k=N+10:-1:N`
	with:
	`for k=10:-1:1`

• The loop counter increments or decrements by 1
• The start value equals the minimum or maximum value of the integer type
• The end value equals the maximum or minimum value of the integer type
The loop covers the full range of the integer type.
	Rewrite the loop casting the type of the loop counter start, step, and end values to a bigger integer or to double For example, rewrite:
	`M= intmin('int16');`
	`N= intmax('int16');`
	`for k=M:N`
	`% Loop body`
	`end`
	to
	`M= intmin('int16');`
	`N= intmax('int16');`
	`for k=int32(M):int32(N)`
	`% Loop body`

Loop conditions causing the error	Workaround
	`end`
• The loop counter increments or decrements by a value not equal to 1 • On last loop iteration, the loop variable value is not equal to the end value **Note:** The software error checking is conservative. It may incorrectly report a loop as being potentially infinite.	Rewrite the loop so that the loop variable on the last loop iteration is equal to the end value.

Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

Type	Description
`char`	Character array (string)
`complex`	Complex data. Cast function takes real and imaginary components
`double`	Double-precision floating point
`int8`, `int16`, `int32`, `int64`	Signed integer
`logical`	Boolean `true` or `false`
`single`	Single-precision floating point
`struct`	Structure
`uint8`, `uint16`, `uint32`, `uint64`	Unsigned integer
Fixed-point	See “Fixed-Point Data Types”.

Defining Data for Code Generation

- "Data Definition for Code Generation" on page 47-2
- "Code Generation for Complex Data" on page 47-4
- "Code Generation for Characters and Strings" on page 47-8
- "Array Size Restrictions for Code Generation" on page 47-9
- "Code Generation for Constants in Structures and Arrays" on page 47-10

Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in the MATLAB environment:

Data	What's Different	More Information
Arrays	Maximum number of elements is restricted	"Array Size Restrictions for Code Generation" on page 47-9
Complex numbers	• Complexity of variables must be set at time of assignment and before first use • Expressions containing a complex number or variable evaluate to a complex result, even if the result is zero **Note:** Because MATLAB does not support complex integer arithmetic, you cannot generate code for functions that use complex integer arithmetic	"Code Generation for Complex Data" on page 47-4
Characters	Restricted to 8 bits of precision	"Code Generation for Characters and Strings" on page 47-8
Enumerated data	• Supports integer-based enumerated types only • Restricted use in `switch` statements and `for`-loops	"Enumerated Data"
Function handles	• Using the same bound variable to reference	"Function Handles"

Data	What's Different	More Information
	different function handles can cause a compile-time error. • Cannot pass function handles to or from primary or extrinsic functions • Cannot view function handles from the debugger	

Code Generation for Complex Data

In this section...
"Restrictions When Defining Complex Variables" on page 47-4
"Code Generation for Complex Data with Zero-Valued Imaginary Parts" on page 47-4
"Results of Expressions That Have Complex Operands" on page 47-7

Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because `x(k) = 3 + 4i` changes the complexity of `x`.

```
function x = test1( )
x = zeros(3,3); % x is real
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to `x`.

```
function x = test1( )
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See "Functions That Sort Complex Values by Absolute Value" on page 47-5.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

  1. Write this function:

     ```
     function myout = mysort(A)
     myout = sort(A);
     end
     ```

  2. Call `mysort` in MATLAB.

     ```
     A = -2:2;
     mysort(A)

     ans =

         -2    -1     0     1     2
     ```

  3. Generate a MEX function for complex inputs.

     ```
     A = -2:2;
     codegen mysort -args {complex(A)} -report
     ```

  4. Call the MEX Function with real inputs.

     ```
     mysort_mex(A)

     ans =
     ```

```
     0     1    -1     2    -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

  1. Write this function:

     ```
     function y = myfun(A)
     x = eig(A);
     y = sort(x,'descend');
     ```

     The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

  2. Call `myfun` in MATLAB.

     ```
     A = [2 3 5;0 5 5;6 7 4];
     myfun(A)
     ```

     ```
     ans =

        12.5777
         2.0000
        -3.5777
     ```

     The result of `eig` is real. Therefore, the inputs to `sort` are real.

  3. Generate a MEX function for complex inputs.

     ```
     codegen myfun -args {complex(A)}
     ```

  4. Call the MEX function.

     ```
     myfun_mex(A)
     ```

     ```
     ans =

        12.5777
        -3.5777
         2.0000
     ```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time, `x` has the value `2 + 3i` and `y` has the value `2 - 3i`. In MATLAB, this code produces the real result `z = 4`. During code generation, the types for `x` and `y` are known, but their values are not known. Because either or both operands in this expression are complex, `z` is defined as a complex variable requiring storage for a real and an imaginary part. `z` equals the complex result `4 + 0i` in generated code, not `4`, as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

  ```
  y = real(x); % y is the real part of the complex number x.
  y = imag(x); % y is the real-valued imaginary part of x.
  y = isreal(x); % y is false (0) for a complex number x.
  ```

- Functions that take real arguments but produce complex results return complex values.

  ```
  z = complex(x,y); % z is a complex number for a real x and y.
  ```

Code Generation for Characters and Strings

The code generation software translates the 16-bit Unicode encoding of a character in MATLAB to an 8-bit encoding that the locale setting determines. The code generation software does not support characters that require more than 1 byte in MATLAB. This restriction applies to constant strings and strings that are passed between MATLAB and the code generation software. For example, the restriction applies to entry-point function inputs and to outputs from extrinsic calls. For code generation, some MATLAB functions accept only 7-bit ASCII strings. See "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2.

If a character is not in the 7-bit ASCII codeset, casting the character to a numeric type, such as double, produces a different result in the generated code than in MATLAB. A best practice for code generation is to avoid performing arithmetic with characters.

More About

- "Locale Settings for MATLAB Process"

Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generation software and the target hardware. The maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generation software reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

See Also

- "Variable-Size Data"

Code Generation for Constants in Structures and Arrays

The code generation software does not recognize constant structure fields or array elements in the following cases:

Fields or elements are assigned inside control constructs

In the following code, the code generation software recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generation software does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generation software does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generation software reports an error.

Constants are assigned to array elements using non-scalar indexing

In the following code, the code generation software recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generation software does not recognize that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1:2) = 20;
y = coder.const(a(1));
```

A function returns a structure or array that has constant and nonconstant elements

For an output structure that has both constant and nonconstant fields, the code generation software does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)
s = create_structure(x);
y = coder.const(s.a);

function s = create_structure(x)
s.a = 10;
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generation software does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

Code Generation for Variable-Size Data

What Is Variable-Size Data?

Variable-size data is data whose size can change at run time. By contrast, fixed-size data is data whose size is known and locked at compile time and, therefore, cannot change at run time.

For example, in the following MATLAB function `nway`, `B` is a variable-size array; its length is not known at compile time.

```
function B = nway(A,n)
% Compute average of every N elements of A and put them in B.
if ((mod(numel(A),n) == 0) && (n >= 1 && n <= numel(A)))
    B = ones(1,numel(A)/n);
    k = 1;
    for i = 1 : numel(A)/n
        B(i) = mean(A(k + (0:n-1)));
        k = k + n;
    end
else
    error('n <= 0 or does not divide number of elements evenly');
end
```

Variable-Size Data Definition for Code Generation

In the MATLAB language, data can vary in size. By contrast, the semantics of generated code constrains the class, complexity, and shape of every expression, variable, and structure field. Therefore, for code generation, you must use each variable consistently. Each variable must:

- Be either complex or real (determined at first assignment)
- Have a consistent shape

  For fixed-size data, the shape is the same as the size returned in MATLAB. For example, if `size(A) == [4 5]`, the shape of variable `A` is 4 x 5. For variable-size data, the shape can be abstract. That is, one or more dimensions can be unknown (such as `4x?` or `?x?`).

By default, the compiler detects code logic that attempts to change these fixed attributes after initial assignments, and flags these occurrences as errors during code generation. However, you can override this behavior by defining variables or structure fields as variable-size data.

For more information, see “Bounded Versus Unbounded Variable-Size Data” on page 48-4

Bounded Versus Unbounded Variable-Size Data

Bounded variable-size data has fixed upper bounds. *Unbounded variable-size data* does not have fixed upper bounds; this data *must* be allocated on the heap and requires dynamic memory allocation. You cannot use dynamic memory allocation for variable-size data in `MATLAB Function` blocks. Use bounded instead of unbounded variable-size data.

Specify Variable-Size Data Without Dynamic Memory Allocation

In this section...
“Fixing Upper Bounds Errors” on page 48-5 “Specifying Upper Bounds for Variable-Size Data” on page 48-5

Fixing Upper Bounds Errors

If MATLAB cannot determine or compute the upper bound, you must specify an upper bound. See “Specifying Upper Bounds for Variable-Size Data” on page 48-5 and “Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 48-19

Specifying Upper Bounds for Variable-Size Data

- “When to Specify Upper Bounds for Variable-Size Data” on page 48-5
- “Specifying Upper Bounds for Local Variable-Size Data” on page 48-5
- “Using a Matrix Constructor with Nonconstant Dimensions” on page 48-6

When to Specify Upper Bounds for Variable-Size Data

When using static allocation on the stack during code generation, MATLAB must be able to determine upper bounds for variable-size data. Specify the upper bounds explicitly for variable-size data from external sources, such as inputs and outputs.

Specifying Upper Bounds for Local Variable-Size Data

When using static allocation, MATLAB uses a sophisticated analysis to calculate the upper bounds of local data at compile time. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you need to specify upper bounds explicitly for local variables.

Constraining the Value of a Variable That Specifies Dimensions of Variable-Size Data

Use the `assert` function with relational operators to constrain the value of variables that specify the dimensions of variable-size data. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L= ones(n,n);
```

```
M = zeros(n,n);
M = [L; M];
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5, defining `L` and `M` as variable-sized matrices with upper bounds of 5 for each dimension.

Specifying the Upper Bounds for All Instances of a Local Variable

Use the `coder.varsize` function to specify the upper bounds for all instances of a local variable in a function. For example:

```
function Y = example_bounds1(u) %#codegen
Y = [1 2 3 4 5];
coder.varsize('Y',[1 10]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

The second argument of `coder.varsize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- First dimension is fixed at size 1
- Second dimension can grow to an upper bound of 10

By default, `coder.varsize` assumes dimensions of 1 are fixed size. For more information, see the `coder.varsize` reference page.

Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a `MATLAB Function` block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

Variable-Size Data in Code Generation Reports

In this section...
"What Reports Tell You About Size" on page 48-7
"How Size Appears in Code Generation Reports" on page 48-8
"How to Generate a Code Generation Report" on page 48-8

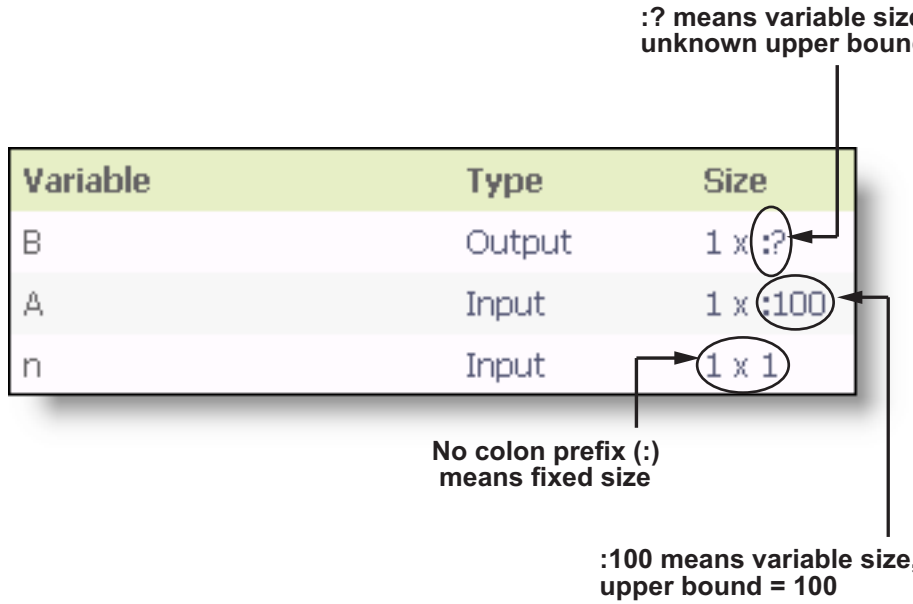
What Reports Tell You About Size

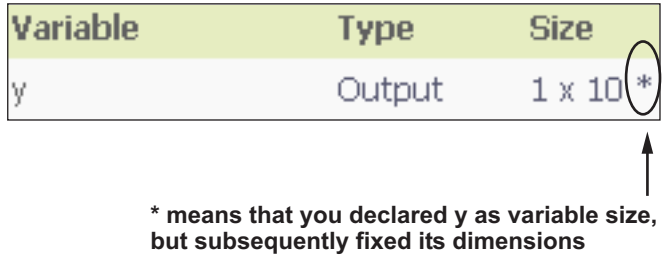
Code generation reports:

- Differentiate fixed-size from variable-size data
- Identify variable-size data with unknown upper bounds
- Identify variable-size data with fixed dimensions

  If you define a variable-size array and then subsequently fix the dimensions of this array in the code, the report appends `*` to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the size of its dimensions does not change during execution.
- Provide guidance on how to fix size mismatch and upper bounds errors.

How Size Appears in Code Generation Reports





How to Generate a Code Generation Report

When you build a Simulink model that contains MATLAB Function blocks, Simulink automatically generates a report in HTML format for each MATLAB Function block in your model. See “MATLAB Function Reports” on page 39-46

Define Variable-Size Data for Code Generation

In this section...
"When to Define Variable-Size Data Explicitly" on page 48-9
"Using a Matrix Constructor with Nonconstant Dimensions" on page 48-9
"Inferring Variable Size from Multiple Assignments" on page 48-10
"Defining Variable-Size Data Explicitly Using coder.varsize" on page 48-11

When to Define Variable-Size Data Explicitly

For code generation, you must assign variables to have a specific class, size, and complexity before using them in operations or returning them as outputs. Generally, you cannot reassign variable properties after the initial assignment. Therefore, attempts to grow a variable or structure field after assigning it a fixed size might cause a compilation error. In these cases, you must explicitly define the data as variable sized using one of these methods:

Method	See
Assign the data from a variable-size matrix constructor such as • `ones` • `zeros` • `repmat`	"Using a Matrix Constructor with Nonconstant Dimensions" on page 48-9
Assign multiple, constant sizes to the same variable before using (reading) the variable.	"Inferring Variable Size from Multiple Assignments" on page 48-10
Define all instances of a variable to be variable sized	"Defining Variable-Size Data Explicitly Using coder.varsize" on page 48-11

Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a `MATLAB Function` block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

Inferring Variable Size from Multiple Assignments

You can define variable-size data by assigning multiple, constant sizes to the same variable before you use (read) the variable in your code. When MATLAB uses static allocation on the stack for code generation, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, MATLAB assumes that the dimension is fixed at that size. The assignments can specify different shapes as well as sizes.

Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function y = var_by_multiassign(u) %#codegen
if (u > 0)
    y = ones(3,4,5);
else
    y = zeros(3,1);
end
```

When static allocation is used, this function infers that `y` is a matrix with three dimensions, where:

- First dimension is fixed at size 3
- Second dimension is variable with an upper bound of 4
- Third dimension is variable with an upper bound of 5

The code generation report represents the size of matrix `y` like this:

Variable	Type	Size
y	Output	3 x :4 x :5

Defining Variable-Size Data Explicitly Using coder.varsize

Use the function `coder.varsize` to define one or more variables or structure fields as variable-size data. Optionally, you can also specify which dimensions vary along with their upper bounds (see "Specifying Which Dimensions Vary" on page 48-11). For example:

- Define `B` as a variable-size 2-by-2 matrix, where each dimension has an upper bound of 64:

  ```
  coder.varsize('B', [64 64]);
  ```

- Define `B` as a variable-size matrix:

  ```
  coder.varsize('B');
  ```

  When you supply only the first argument, `coder.varsize` assumes all dimensions of `B` can vary and that the upper bound is `size(B)`.

For more information, see the `coder.varsize` reference page.

Specifying Which Dimensions Vary

You can use the function `coder.varsize` to specify which dimensions vary. For example, the following statement defines `B` as a row vector whose first dimension is fixed at 2, but whose second dimension can grow to an upper bound of 16:

```
coder.varsize('B',[2, 16],[0 1])
```

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size; dimensions that correspond to ones or `true` vary in size. `coder.varsize` usually treats dimensions of size 1 as fixed (see "Defining Variable-Size Matrices with Singleton Dimensions" on page 48-12).

For more information about the syntax, see the `coder.varsize` reference page.

Allowing a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix `Y` with fixed 2-by-2 dimensions before first use (where the statement `Y = Y + u` reads from `Y`). However, `coder.varsize` defines `Y` as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
```

```
if (u > 0)
    Y = zeros(2,2);
    coder.varsize('Y');
    if (u < 10)
        Y = Y + u;
    end
else
    Y = zeros(5,5);
end
```

Without `coder.varsize`, MATLAB infers `Y` to be a fixed-size, 2-by-2 matrix and generates a size mismatch error during code generation.

Defining Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A,dim)` = 1. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder.varsize` expressions.

  For example, in this function, `Y` behaves like a vector with one variable-size dimension:

  ```
  function Y = dim_singleton(u) %#codegen
  Y = [1 2];
  coder.varsize('Y', [1 10]);
  if (u > 0)
      Y = [Y 3];
  else
      Y = [Y u];
  end
  ```

- You initialize variable-size data with singleton dimensions using matrix constructor expressions or matrix functions.

  For example, in this function, both `X` and `Y` behave like vectors where only their second dimensions are variable sized:

  ```
  function [X,Y] = dim_singleton_vects(u) %#codegen
  Y = ones(1,3);
  X = [1 4];
  coder.varsize('Y','X');
  if (u > 0)
      Y = [Y u];
  else
  ```

```
        X = [X u];
    end
```

You can override this behavior by using `coder.varsize` to specify explicitly that singleton dimensions vary. For example:

```
function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder.varsize('Y', [1 10], [1 1]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

In this example, the third argument of `coder.varsize` is a vector of ones, indicating that each dimension of `Y` varies in size. For more information, see the `coder.varsize` reference page.

Defining Variable-Size Structure Fields

To define structure fields as variable-size arrays, use colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable sized. For example:

```
function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.varsize('data(:).values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end;
end
```

The expression `coder.varsize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable sized.

Here are other examples:

- `coder.varsize('data.A(:).B')`

  In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.varsize('data(:).A(:).B')`

  This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable sized.

C Code Interface for Arrays

C Code Interface for Statically Allocated Arrays

For statically allocated arrays, the generated code contains the definition of the array and the size of the array.

For example, consider the MATLAB function `myuniquetol`.

```
function B = myuniquetol(A, tol) %#codegen
A = sort(A);
coder.varsize('B', [1 100], [0 1]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

The statement `coder.varsize('B', [1 100], [0 1])` specifies that `B` is a variable-size array whose first dimension is fixed at 1 and second dimension can vary up to 100 elements. Without this statement, `B` is a dynamically allocated array.

Generate code for `myuniquetol` specifying that input `A` is a variable-size real double vector whose first dimension is fixed at 1 and second dimension can vary up to 100 elements.

```
codegen -config:lib -report myuniquetol -args {coder.typeof(0,[1 100],1),coder.typeof(0)}
```

In the generated code, the function declaration is:

```
extern void myuniquetol(const double A_data[], const int A_size[2], double tol,
  double B_data[], int B_size[2])
```

The function signature declares the input argument `A` and the output argument `B`. `A_size` contains the size of `A`. `B_size` contains the size of `B` after the call to `myuniquetol`. Use `B_size` to determine the number of elements of `B` that you can access after the call to `myuniquetol`. `B_size[0]` contains the size of the first dimension. `B_size[1]` contains the size of the second dimension. Therefore, the number of elements

of `B` is `B_size[0]*B_Size[1]`. Even though `B` has `100` elements in the C code, only `B_size[0]*B_Size[1]` elements contain valid data.

The following C main function shows how to call `myuniquetol`.

```
void main()
{
        double A[100], B[100];
        int A_size[2] = { 1, 100 };
        int B_size[2];
        int i;
        for (i = 0; i < 100; i++) {
             A[i] = (double)1/i;
       }
       myuniquetol(A, A_size, 0.1, B, B_size);
}
```

Diagnose and Fix Variable-Size Data Errors

In this section...

"Diagnosing and Fixing Size Mismatch Errors" on page 48-17
"Diagnosing and Fixing Errors in Detecting Upper Bounds" on page 48-19

Diagnosing and Fixing Size Mismatch Errors

Check your code for these issues:

Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix `A` to grow by adding the `coder.varsize` construct:

  ```
  function Y = example_mismatch1_fix1(n) %#codegen
  coder.varsize('A');
  assert(n < 10);
  B = ones(n,n);
  A = magic(3);
  A(1) = mean(A(:));
  if (n == 3)
      A = B;
  end
  ```

```
Y = A;
```

- Explicitly restrict the size of matrix `B` to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Use explicit indexing to make `B` the same size as `A`:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B(1:3, 1:3);
end
Y = A;
```

Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder.varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder.varsize('Y', [1 10]);
if u < 0
    Y = [Y u];
end
```

In this example, `coder.varsize` defines `Y` as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of `Y` as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder.varsize` specification.

Performing Binary Operations on Fixed and Variable-Size Operands

You cannot perform binary operations on operands of different sizes. Operands have different sizes if one has fixed dimensions and the other has variable dimensions. For example:

```
function z = mismatch_operands(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x + y;
```

When you compile this function, you get an error because `y` has fixed dimensions (3 x 3), but `x` has variable dimensions. Fix this problem by using explicit indexing to make `x` the same size as `y`:

```
function z = mismatch_operands_fix(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x(1:3,1:3) + y;
```

Diagnosing and Fixing Errors in Detecting Upper Bounds

Check your code for these issues:

Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
```

```
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

Incompatibilities with MATLAB in Variable-Size Support for Code Generation

"Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements" on page 48-28
"Dynamic Memory Allocation Not Supported for MATLAB Function Blocks" on page 48-29

Incompatibility with MATLAB for Scalar Expansion

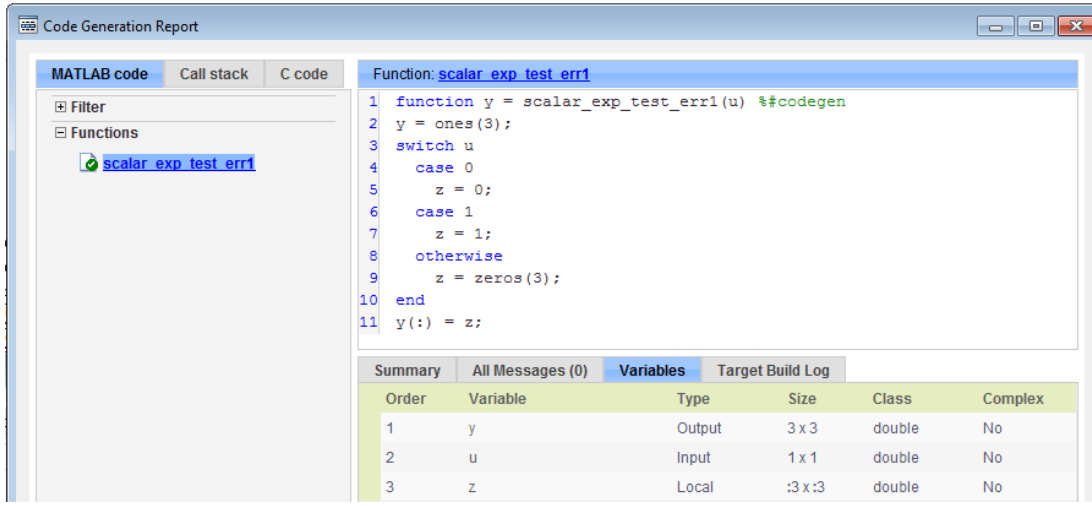
Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. Except for some matrix operators, MATLAB arithmetic operators work on corresponding elements of arrays with equal dimensions. For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. If one operand is a scalar and the other is not, MATLAB applies the scalar to every element of the other operand—this property is known as *scalar expansion*.

During code generation, the standard MATLAB scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Instead, it generates a size mismatch error at run time for MEX functions. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior.

For example, in the following function, `z` is scalar for the `switch` statement `case 0` and `case 1`. MATLAB applies scalar expansion when evaluating `y(:) = z;` for these two cases.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generation software determines that `z` is variable size with an upper bound of `3`.



If you run the MEX function with `u` equal to zero or one, even though `z` is scalar at run time, the generated code does not perform scalar expansion and a run-time error occurs.

```
scalar_exp_test_err1_mex(0)
Sizes mismatch: 9 ~= 1.

Error in scalar_exp_test_err1 (line 11)
```

```
y(:) = z;
```

Workaround

Use indexing to force `z` to be a scalar value:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z(1);
```

Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `:?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

  For example, `size(A,n)` returns the same answer in generated code and MATLAB code.
- Rewrite `size(A)`:

```
B = size(A);
X = B(1:ndims(A));
```

This version returns `X` with a variable-length output. However, you cannot pass a variable-size `X` to matrix constructors such as `zeros` that require a fixed-size argument.

Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be `1x0` or `0x1` in generated code, but `0x0` in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen
x = [];
i = 0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = [];
end
y = size(x);
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation the scalar value has size `1x1` and `x` has size `0x0`. To support this use case, the code generation software determines the size for `x` as `[1 x :?]`. Because there is another assignment `x = []` after the concatenation, the size of `x` in the generated code is `1x0` instead of `0x0`.

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 43-10.

Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.

- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = zeros(1,0);
end
y=size(x);
end
```

Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```
function y = fun(n)
x = [];
if n > 1
    x = ['a' x];
end
y=class(x);
end
```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generation software considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```
function y = fun(n)
x = blanks(0);
if n > 1
```

```
    x = ['a' x];
end
y=class(x);
end
```

Incompatibility with MATLAB in Vector-Vector Indexing

In vector-vector indexing, you use one vector as an index into another vector. When either vector is variable sized, you might get a run-time error during code generation. Consider the index expression `A(B)`. The general rule for indexing is that `size(A(B)) == size(B)`. However, when both `A` and `B` are vectors, MATLAB applies a special rule: use the orientation of A as the orientation of the output. For example, if `size(A) == [1 5]` and `size(B) == [3 1]`, then `size(A(B)) == [1 3]`.

In this situation, if the code generation software detects that both `A` and `B` are vectors at compile time, it applies the special rule and gives the same result as MATLAB. However, if either `A` or `B` is a variable-size matrix (has shape `?x?`) at compile time, the code generation software applies only the general indexing rule. Then, if both `A` and `B` become vectors at run time, the code generation software reports a run-time error when you run the MEX function. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior. It is best practice to generate and test a MEX function before generating C code.

Workaround

Force your data to be a vector by using the colon operator for indexing: `A(B(:))`. For example, suppose your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing:

```
...
if isvector(A) && isvector(B)
    C = A(:);
    D = C(B(:));
else
    D = A(B);
end
...
```

The indexing in the first branch specifies that `C` and `B(:)` are compile-time vectors. As a result, the code generation software applies the standard vector-vector indexing rule.

Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitations apply to matrix indexing operations for code generation:

- Initialization of the following style:

  ```
  for i = 1:10
      M(i) = 5;
  end
  ```

  In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

  For code generation, preallocate `M` as highlighted in the following code.

  ```
  M = zeros(1,10);
  for i = 1:10
      M(i) = 5;
  end
  ```

- `M(i:j)` where `i` and `j` change in a loop

  During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown in the following example:

  ```
  ...
  M = ones(10,10);
  for i = 1:10
      for j = i:10
          M(i,j) = 2*M(i,j);
      end
  end
  ...
  ```

  Note: The matrix `M` must be defined before entering the loop, as shown in the highlighted code.

Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- `c` is a variable-size cell array.
- You access the contents of `c` by using curly braces. For example, `c{2:4}`.
- You include the results in concatenation. For example, `[a c{2:4} b]`.
- `c{I}` returns no elements. Either `c` is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits `c{I}` from the concatenation. For example, `[a c{I} b]` becomes `[a b]`. The code generation software treats `c{I}` as the empty array `[c{I}]`. The concatenation becomes `[...[c{i}]...]`. This concatenation then omits the array `[c{I}]`. So that the properties of `[c{I}]` are compatible with the concatenation `[...[c{i}]...]`, the code generation software assigns the class, size, and complexity of `[c{I}]` according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of `Ni` depends on whether the corresponding dimension in the base type is fixed or variable size.
    - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
    - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `:10x7x8x:?`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

  When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See "Valid Combinations of Unlike Classes". In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[... [c{I}]...]` because the code generation software treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.

- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

  In MATLAB, the concatenation `[c{I}]` is a 0x0 double. In the generated code, the previously described rules determine the size of `[c{I}]`.

Dynamic Memory Allocation Not Supported for MATLAB Function Blocks

You cannot use dynamic memory allocation for variable-size data in `MATLAB Function` blocks. Use bounded instead of unbounded variable-size data.

Variable-Sizing Restrictions for Code Generation of Toolbox Functions

In this section...

"Common Restrictions" on page 48-30
"Toolbox Functions with Restrictions For Variable-Size Data" on page 48-31

Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in "Toolbox Functions with Restrictions For Variable-Size Data" on page 48-31.

Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape `1x:n` or `:nx1` (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

Automatic dimension restriction

When the function selects the working dimension automatically, it bases the selection on the upper bounds for the dimension sizes. In the case of the `sum` function, `sum(X)` selects its working dimension automatically, while `sum(X, dim)` uses `dim` as the explicit working dimension.

For example, if `X` is a variable-size matrix with dimensions `1x:3x:5`, `sum(x)` behaves like `sum(X,2)` in generated code. In MATLAB, it behaves like `sum(X,2)` provided `size(X,2)` is not 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`. Consequently, you get a run-time error if an automatically selected working dimension assumes a length of 1 at run time.

To avoid the issue, specify the intended working dimension explicitly as a constant value.

Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

Array-to-scalar restriction

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

Toolbox Functions with Restrictions For Variable-Size Data

The following table list functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for code generation, see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List".

Function	Restrictions for Variable-Size Data
`all`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
`any`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
`bsxfun`	• Dimensions expand only where one input array or the other has a fixed length of 1.
`cat`	• Dimension argument must be a constant. • An error occurs if variable-size inputs are empty at run time.
`conv`	• See "Variable-length vector restriction" on page 48-30. • Input vectors must have the same orientation, either both row vectors or both column vectors.
`cov`	• For `cov(X)`, see "Array-to-vector restriction" on page 48-30.
`cross`	• Variable-size array inputs that become vectors at run time must have the same orientation.
`deconv`	• For both arguments, see "Variable-length vector restriction" on page 48-30.

Function	Restrictions for Variable-Size Data
`detrend`	• For first argument for row vectors only, see "Array-to-vector restriction" on page 48-30 .
`diag`	• See "Array-to-vector restriction" on page 48-30 .
`diff`	• See "Automatic dimension restriction" on page 48-30. • Length of the working dimension must be greater than the difference order input when the input is variable sized. For example, if the input is a variable-size matrix that is 3-by-5 at run time, `diff(x,2,1)` works but `diff(x,5,1)` generates a run-time error.
`fft`	• See "Automatic dimension restriction" on page 48-30.
`filter`	• For first and second arguments, see "Variable-length vector restriction" on page 48-30. • See "Automatic dimension restriction" on page 48-30.
`hist`	• For second argument, see "Variable-length vector restriction" on page 48-30. • For second input argument, see "Array-to-scalar restriction" on page 48-31.
`histc`	• See "Automatic dimension restriction" on page 48-30.
`ifft`	• See "Automatic dimension restriction" on page 48-30.
`ind2sub`	• First input (the size vector input) must be fixed size.
`interp1`	• For the `xq` input, see "Array-to-vector restriction" on page 48-30. • If `v` becomes a row vector at run time, the array to vector restriction applies. If `v` becomes a column vector at run time, this restriction does not apply.
`ipermute`	• Order input must be fixed size.

Function	Restrictions for Variable-Size Data
`issorted`	• For optional rows input, see "Variable-length vector restriction" on page 48-30.
`magic`	• Argument must be a constant. • Output can be fixed-size matrices only.
`max`	• See "Automatic dimension restriction" on page 48-30.
`mean`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`median`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`min`	• See "Automatic dimension restriction" on page 48-30.
`mode`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`mtimes`	• When an input is variable-size, MATLAB determines whether to generate code for a general matrix*matrix multiplication or a scalar*matrix multiplication, based on whether one of the arguments is a fixed-size scalar. If neither argument is a fixed-size scalar, the inner dimensions of the two arguments must agree even if a variable-size matrix input is a scalar at run time.
`nchoosek`	• The second input, `k`, must be a fixed-size scalar. • The second input, `k`, must be a constant for static allocation.. • You cannot create a variable-size array by passing in a variable, `k`, .
`permute`	• Order input must be fixed-size.

Function	Restrictions for Variable-Size Data
`planerot`	• Input must be a fixed-size, two-element column vector. It cannot be a variable-size array that takes on the size 2-by-1 at run time.
`poly`	• See "Variable-length vector restriction" on page 48-30.
`polyfit`	• For first and second arguments, see "Variable-length vector restriction" on page 48-30.
`prod`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`rand`	• For an upper-bounded variable `N`, `rand(1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `rand([1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.
`randi`	• For an upper-bounded variable `N`, `randi(imax,1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `randi(imax,[1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.
`randn`	• For an upper-bounded variable `N`, `randn(1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `randn([1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.

Function	Restrictions for Variable-Size Data
`reshape`	• If the input is a variable-size array and the output array has at least one fixed-length dimension, do not specify the output dimension sizes in a size vector `sz`. Instead, specify the output dimension sizes as scalar values, `sz1,...,szN`. Specify fixed-size dimensions as constants. • When the input is a variable-size empty array, the maximum dimension size of the output array (also empty) cannot be larger than that of the input.
`roots`	• See "Variable-length vector restriction" on page 48-30.
`shiftdim`	• If you do not supply the second argument, the number of shifts is determined at compilation time by the upper bounds of the dimension sizes. Consequently, at run time the number of shifts is constant. • An error occurs if the dimension that is shifted to the first dimension has length 1 at run time. To avoid the error, supply the number of shifts as the second input argument (must be a constant). • First input argument must have the same number of dimensions when you supply a positive number of shifts.
`std`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.
`sub2ind`	• First input (the size vector input) must be fixed size.
`sum`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`trapz`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.

Function	Restrictions for Variable-Size Data
`typecast`	• See "Variable-length vector restriction" on page 48-30 on first argument.
`var`	• See "Automatic dimension restriction" on page 48-30. • An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.

Code Generation for MATLAB Structures

- "Structure Definition for Code Generation" on page 49-2
- "Structure Operations Allowed for Code Generation" on page 49-3
- "Define Scalar Structures for Code Generation" on page 49-4
- "Define Arrays of Structures for Code Generation" on page 49-6
- "Make Structures Persistent" on page 49-8
- "Index Substructures and Fields" on page 49-9
- "Assign Values to Structures and Fields" on page 49-11
- "Pass Large Structures as Input Parameters" on page 49-13

Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

What's Different	More Information
Use a restricted set of operations.	“Structure Operations Allowed for Code Generation” on page 49-3
Observe restrictions on properties and values of scalar structures.	“Define Scalar Structures for Code Generation” on page 49-4
Make structures uniform in arrays.	“Define Arrays of Structures for Code Generation” on page 49-6
Reference structure fields individually during indexing.	“Index Substructures and Fields” on page 39-79
Avoid type mismatch when assigning values to structures and fields.	“Assign Values to Structures and Fields” on page 39-83

Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Define structures as local and persistent variables by assignment and using the `struct` function
- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

Define Scalar Structures for Code Generation

In this section...
"Restrictions When Defining Scalar Structures by Assignment" on page 49-4
"Adding Fields in Consistent Order on Each Control Flow Path" on page 49-4
"Restriction on Adding New Fields After First Use" on page 49-5

Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a',  0, 'b',  1, 'c',  2);
p = S;
...
```

Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
   x.a = 10;
   x.b = 20;
else
   x.b = 30;  % Generates an error (on variable x)
   x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
   x.a = 10;
   x.b = 20;
else
   x.a = 40;
   x.b = 30;
end
y = x.a + x.b;
```

Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

Define Arrays of Structures for Code Generation

In this section...
"Ensuring Consistency of Fields" on page 49-6
"Using repmat to Define an Array of Structures with Consistent Field Properties" on page 49-6
"Defining an Array of Structures by Using struct" on page 49-7
"Defining an Array of Structures Using Concatenation" on page 49-7

Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size using `coder.varsize`. For more information, see "Declare a Variable-Size Structure Field.".

Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

1. Create a scalar structure, as described in "Define Scalar Structures for Code Generation" on page 49-4.
2. Call `repmat`, passing the scalar structure and the dimensions of the array.
3. Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,3);
```

```
X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...
```

Defining an Array of Structures by Using `struct`

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets (`[ ]`), to join one or more structures into an array (see "Concatenating Matrices"). For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```
...
W = [ sab(1,2) sab(2,3) sab(4,5) ];

function s = sab(a,b)
  s.a = a;
  s.b = b;
...
```

Make Structures Persistent

To make structures persist, you define them to be persistent variables and initialize them with the `isempty` statement, as described in "Define and Initialize Persistent Variables" on page 46-10.

For example, the following function defines structure `X` to be persistent and initializes its fields `a` and `b`:

```
function f(u)  %#codegen
persistent X

if isempty(X)
   X.a = 1;
   X.b = 2;
end
```

Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```
...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                  'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...
```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

Dot Notation	Symbol Resolution
`substruct1.a1`	Field `a1` of local structure `substruct1`
`substruct2.ele3.a1`	Value of field `a1` of field `ele3`, a substructure of local structure `substruct2`
`substruct2.ele3.a2(1,1)`	Value in row 1, column 1 of field `a2` of field `ele3`, a substructure of local structure `substruct2`

Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```
...
y = X(1).a % Extracts the value of field a
           % of the first structure in array X
...
```

To reference all the values of a particular field for each structure in an array, use this notation in a `for` loop, as in this example:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
    X(i).a = i;
    X(i).b = i+1;
end
```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See "Define Arrays of Structures for Code Generation" on page 49-6 for more information.

Do not reference fields dynamically

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see "Generate Field Names from Variables").

Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

Field properties must be consistent across structure-to-structure assignments

If:	Then:
Assigning one structure to another structure.	Define each structure with the same number, type, and size of fields.
Assigning one structure to a substructure of a different structure and vice versa.	Define the structure with the same number, type, and size of fields as the substructure.
Assigning an element of one structure to an element of another structure.	The elements must have the same type and size.

For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generation software recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generation software does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generation software reports an error.

Do not assign mxArrays to structures

You cannot assign `mxArrays` to structure elements; convert `mxArrays` to known types before code generation (see "Working with mxArrays" on page 55-17).

Do not assign classes to structure fields

You cannot assign classes to structure fields.

Do not assign cell arrays to structure fields

You cannot assign cell arrays to structure fields.

Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generation software allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where `S` is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

Code Generation for Cell Arrays

- "Homogeneous vs. Heterogeneous Cell Arrays" on page 50-2
- "Control Whether a Cell Array is Homogeneous or Heterogeneous" on page 50-4
- "Cell Array Requirements and Limitations for Code Generation" on page 50-5
- "Cell Arrays in Code Generation Reports" on page 50-9

Homogeneous vs. Heterogeneous Cell Arrays

The code generation software classifies a cell array as *homogeneous* or *heterogeneous*. This classification determines how a cell array is represented in the generated C/C++ code. It also determines how you can use the cell array in MATLAB code from which you generate C/C++ code.

A homogeneous cell array has the following characteristics:

- The cell array is represented as a C array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable size.
- You can index into the cell array using an index whose value is determined at run time.

A heterogeneous cell array has the following characteristics:

- The cell array is represented as a C structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable size.
- You must index into the cell array using a constant index or using `for`-loops with constant bounds.

The code generation software uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors such as how you use the cell array in your program. A particular cell array can be homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. This cell array can be a heterogeneous 1x2 cell array whose first element is double scalar and whose second element is a 1x2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the cell array is a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

To see whether a cell array is homogeneous or heterogeneous, view the variable in the code generation report. See “Cell Arrays in Code Generation Reports” on page 50-9.

For more information, see “Control Whether a Cell Array is Homogeneous or Heterogeneous” on page 50-4.

More About

- “Cell Array Requirements and Limitations for Code Generation” on page 50-5

Control Whether a Cell Array is Homogeneous or Heterogeneous

As long as you do not specify conflicting requirements, you can control whether a cell array is homogeneous or heterogeneous.

- If you use `coder.varsize` with the cell array, the cell array is homogeneous.
- If you index the cell array with an index whose value is determined at run time, the cell array is homogeneous.
- If you use `coder.cstructname` with the cell array, the cell array is heterogeneous.
- If the elements have different classes, the cell array is heterogeneous.

If the code generation software detects conflicting requirements for a cell array, the code generation fails. For example, you cannot use `coder.varsize` with a cell array whose elements have different classes.

See Also

`coder.cstructname` | `coder.varsize`

More About

- “Homogeneous vs. Heterogeneous Cell Arrays” on page 50-2

Cell Array Requirements and Limitations for Code Generation

Cell Array Definition

- You must completely assign cell arrays at compile time. You must assign each cell array element on all execution paths.

  If you use `cell` to create a cell array, you must assign values to all elements of the cell array. The following code is not allowed because `y{2}` is not assigned.

  ```
  function y = foo()
  y = cell(1,3);
  y{1} = 1;
  y{3} = 3;
  end
  ```

  Even if the element is not used, you must assign a value so that the code generation software can determine whether the cell array is homogeneous or heterogeneous. Assign a value that is consistent with how you plan to use the cell array.

  In the preceding example, if `y{2}` is double, `y` is homogeneous. If `y{2}` is empty, its size is `0x0` not `1x1` like the other elements. In this case, `y` is heterogeneous.

- The assignment must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

  ```
  function y = foo(n)
  y = cell(1,3)
  if n > 1;
      y{1} = 1
      y{2} = 2;
      y{3} = 3;
  else
      y{1} = 10;
      y{2} = 'a';
      y{3} = 30;
  end
  ```

Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses `()`. Instead, consider indexing cell arrays by using curly braces `{}` to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indexes or by using `for`-loops with constant bounds.

  For example, the following code is not allowed:

  ```
  x = {1, 'mystring'};
  disp(x{randi});
  ```

  If the index `A` and `B` are constant, the following code is allowed:

  ```
  x = {1, 'mystring'};
  for i = A:B
    disp(x{i});
  end
  ```

  When the `for`-loop has constant bounds, it is unrolled. For large cell arrays, the unrolling can increase compile time and generate inefficient code.

Growing a Cell Array by Using {end + 1}

To grow a cell array `X`, you can use `X{end + 1}`. For example:

```
X = {1 2};
X{end + 1} = 'a';
```

When you use `{end + 1}` to grow a cell array, follow these restrictions:

- Use only `{end + 1}`. Do not use `{end + 2}`, `{end + 3}`, and so on.
- Use `{end + 1}` with compile-time vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector:

  ```
  X = {1 2; 3 4};
  X{end + 1} = 5;
  ```

- Use `{end + 1}` only with a variable. In the following code, `{end + 1}` does not cause `{1 2 3}` to grow. In this case, the code generation software treats `{end + 1}` as an out-of-bounds index into `X{2}`.

  ```
  X = {'a' { 1 2 3 }};
  ```

```
X{2}{end + 1} = 4;
```

- When `{end + 1}` grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous.

  This code is allowed because `X` is homogeneous.

  ```
  X = {1  2};
  for i=1:n
      X{end + 1} = 3;
  end
  ```

  This code is not allowed because `X` is heterogeneous.

  ```
  X = {1 'a' 2 'b'};
  for i=1:n
      X{end + 1} = 3;
  end
  ```

Variable-Size Cell Arrays

- Heterogeneous cell arrays cannot be variable-size.
- You cannot use the `cell` function to create a variable-size cell array. Consider the following code:

  ```
  function y = foo(n)
  y = cell(1,n);
  ...
  ```

  If `n` is a compile-time constant, this code is allowed because `y` has a fixed size. However, if the value of `n` is not known at compile time, this code is not allowed because `y` has a variable size. Instead, use `repmat`. For example:

  ```
  function y = foo(n)
  y = repmat({1}, [1 n]);
  ...
  ```

- You cannot use the `cell` function with `coder.varsize` to make a variable-size cell array. For example, the following code is not allowed:

  ```
  function y = foo()
  coder.varsize('y')
  y = cell(1,2);
  ...
  ```

Cell Array Contents

Cell arrays cannot contain `mxarrays`. In a cell array, you cannot store a value that an extrinsic function returns.

Cell Arrays in Structures

Structures cannot contain cell arrays.

Passing to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

Use in `MATLAB Function` Block

You can use cells arrays inside a `MATLAB Function` block. You cannot use cell arrays for Simulink signals, parameters, or data store memory.

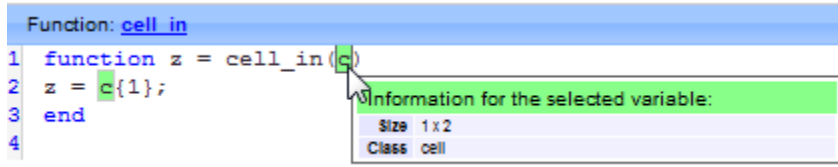
- “Differences in Behavior After Compiling MATLAB Code” on page 43-8

Cell Arrays in Code Generation Reports

Cell Array Variable in the MATLAB Code Pane

When you place your cursor over a cell array variable in the **MATLAB code** pane, the report shows that the variable has class `cell`.

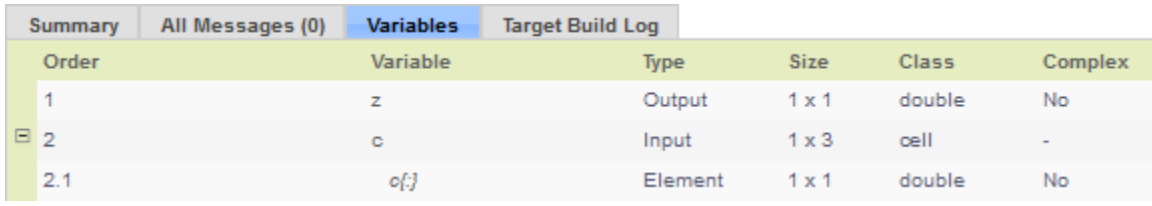


If the cell array has all constant elements, or some constant and some nonconstant elements, the variable name is orange. When you place your cursor over the variable, the report shows the values of the elements. The report displays a nonconstant element as an empty array. If you export the cell array variable to the base workspace, a nonconstant element is an empty array in the base workspace. See "MATLAB Code Variables in a Report" on page 39-50.

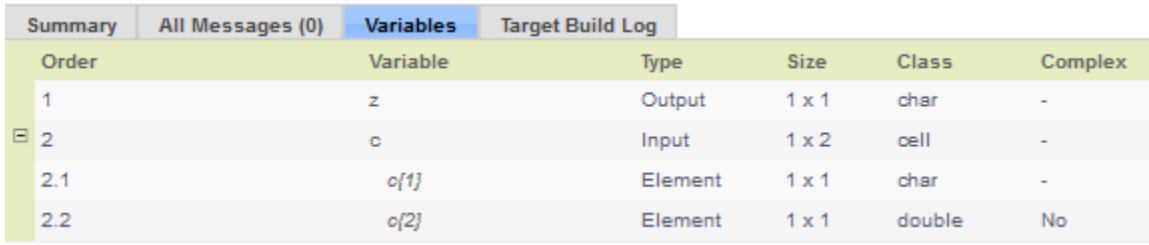
Cell Array Variable on the Variables Tab

On the **Variables** tab, for a cell array, the report shows class `cell`. By default, the report collapses the list of cell array elements. To see the properties of the elements, expand the list.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.



For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.



Order	Variable	Type	Size	Class	Complex
1	z	Output	1 x 1	char	-
2	c	Input	1 x 2	cell	-
2.1	*c{1}*	Element	1 x 1	char	-
2.2	*c{2}*	Element	1 x 1	double	No

Code Generation for Enumerated Data

- "Enumerated Data Definition for Code Generation" on page 51-2
- "Customize Enumerated Types for MATLAB Function Blocks" on page 51-3
- "Restrictions on Use of Enumerated Data in `for`-Loops" on page 51-4
- "Toolbox Functions That Support Enumerated Types for Code Generation" on page 51-5

Enumerated Data Definition for Code Generation

To generate efficient standalone code for enumerated data, you must define and use enumerated types differently than you do in the MATLAB environment:

Difference	More Information
Supports integer-based enumerated types only	"Enumerated Types Supported in MATLAB Function Blocks" on page 39-102
Each enumerated data type must be defined in a separate file on the MATLAB path	"Define Enumerated Data Types for MATLAB Function Blocks" on page 39-105
Restricted set of operations	"Operations on Enumerated Data" on page 39-115
Restricted use in `for`-loops	"Restrictions on Use of Enumerated Data in `for`-Loops" on page 51-4

Customize Enumerated Types for MATLAB Function Blocks

To customize an enumerated type that you use in a MATLAB Function block, use the same techniques that work with MATLAB classes, as described in Modifying Superclass Methods and Properties. For more information, see “Customize Simulink Enumeration” on page 58-9.

Restrictions on Use of Enumerated Data in `for`-Loops

Do not use enumerated data as the loop counter variable in `for`- loops

To iterate over a range of enumerated data with consecutive values, in the loop counter, cast the enumerated data to a built-in integer type. The size of the built-in integer type must be big enough to contain the enumerated value.

For example, suppose you define an enumerated type `ColorCodes` as follows:

```
classdef ColorCodes < int32
    enumeration
        Red(1),
        Blue(2),
        Green(3),
        Yellow(4),
        Purple(5)
    end
end
```

Because the enumerated values are consecutive, you can use `ColorCodes` data in a `for`-loop like this:

```
...
for i = int32(ColorCodes.Red):int32(ColorCodes.Purple)
     c = ColorCodes(i);
     ...
end
```

Toolbox Functions That Support Enumerated Types for Code Generation

The following MATLAB toolbox functions support enumerated types for code generation:

- `cast`
- `cat`
- `circshift`
- `fliplr`
- `flipud`
- `histc`
- `intersect`
- `ipermute`
- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`

- `union`
- `unique`

Code Generation for MATLAB Classes

- "System Objects Requirements and Limitations for Code Generation" on page 52-25

MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

What's Different	More Information
Class must be in a single file. Because of this limitation, code generation is not supported for a class definition that uses an `@`-folder.	"Create a Single, Self-Contained Class Definition File"
Restricted set of language features.	"Language Limitations" on page 52-2
Restricted set of code generation features.	"Code Generation Features Not Compatible with Classes" on page 52-3
Definition of class properties.	"Defining Class Properties for Code Generation" on page 52-4
Use of handle classes.	"Generate Code for MATLAB Handle Classes and System Objects" on page 52-14 "Handle Object Limitations for Code Generation" on page 52-22
Calls to base class constructor.	"Calls to Base Class Constructor" on page 52-5
Global variables containing MATLAB objects are not supported for code generation.	N/A
Inheritance from built-in MATLAB classes is not supported.	"Inheritance from Built-In MATLAB Classes Not Supported" on page 52-7

Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events

- Listeners
- Arrays of objects
- Recursive data structures
  - Linked lists
  - Trees
  - Graphs
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

  In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.
- The `empty` method

  In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.
- The following MATLAB handle class methods:
  - `addlistener`
  - `delete`
  - `eq`
  - `findobj`
  - `findpro`
- The `AbortSet` property attribute

Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

  For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

  ```
  codegen ClassNameA
  ```
- If an entry-point MATLAB function has an input or output that is a MATLAB class, you cannot generate code for this function.

For example, if function `foo` takes one input, `a`, that is a MATLAB object, you cannot generate code for `foo` by executing:

```
codegen foo -args {a}
```

- Code generation does not support classes in matrices or structures. As a workaround, consider using cell arrays because code generation supports classes in cell arrays.
- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v;` is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to the `coder.ceval` function.
- If you use classes in code in the `MATLAB Function` block, you cannot use the debugger to view class information.
- The `coder.nullcopy` function does not support MATLAB classes as inputs.

Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you do when running your code in the MATLAB environment:

- Code generation does not support the property restriction syntax. For example, the following class definition is not allowed because it uses the property restriction syntax to restrict the types of the `Number` and `Today` properties.

  ```
  classdef Myclass
     properties
        Number double
        Today char = date;
     end
  end
  ```

- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

  When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generation

software requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:
  - If the property does not have an explicit initial value, the code generation software assumes that it is undefined at the beginning of the constructor. The code generation software does not assign an empty matrix as the default.
  - If the property does not have an initial value and the code generation software cannot determine that the property is assigned prior to first use, the software generates a compilation error.
  - For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

    For example, for a nontunable property, you can use the following assignment:

    ```
    mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
    ```

    You cannot use the following partial assignments:

    ```
    mySystemObject.nonTunableProperty.fieldA = a;
    mySystemObject.nonTunableProperty.fieldB = b;
    ```
  - If dynamic memory allocation is enabled, code generation supports variable-size properties for handle classes. Without dynamic memory allocation, you cannot generate code for handle classes that have variable-size properties.
  - `coder.varsize` is not supported for class properties.
- MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.

Calls to Base Class Constructor

If a class constructor contains a call to the constructor of the base class, the call to the base class constructor must come before `for`, `if`, `return`, `switch` or `while` statements.

For example, if you define a class `B` based on class `A`:

```
classdef B < A
    methods
```

```
        function obj = B(varargin)
            if nargin == 0
                a = 1;
                b = 2;
            elseif nargin == 1
                a = varargin{1};
                b = 1;
            elseif nargin == 2
                a = varargin{1};
                b = varargin{2};
            end
            obj = obj@A(a,b);
        end

    end
end
```

Because the class definition for `B` uses an `if` statement before calling the base class constructor for `A`, you cannot generate code for function `callB`:

```
function [y1,y2] = callB
x = B;
y1 = x.p1;
y2 = x.p2;
end
```

However, you can generate code for `callB` if you define class `B` as:

```
classdef B < A
    methods
        function obj = NewB(varargin)
            [a,b] = getaandb(varargin{:});
            obj = obj@A(a,b);
        end

    end
end

function [a,b] = getaandb(varargin)
if nargin == 0
    a = 1;
    b = 2;
elseif nargin == 1
    a = varargin{1};
    b = 1;
```

```
elseif nargin == 2
    a = varargin{1};
    b = varargin{2};
end
end
```

Inheritance from Built-In MATLAB Classes Not Supported

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

To generate code for:	Example:
Value classes	"Generate Code for MATLAB Value Classes" on page 52-9
Handle classes including user-defined System objects	"Generate Code for MATLAB Handle Classes and System Objects" on page 52-14

For more information, see:

- "Role of Classes in MATLAB"
- "MATLAB Classes Definition for Code Generation" on page 52-2

Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

1 In a writable folder, create a MATLAB value class, `Shape`. Save the code as `Shape.m`.

```
classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
    properties
        centerX;
        centerY;
    end
    properties (Dependent = true)
        area;
    end
    methods
        function out = get.area(obj)
            out =  obj.getarea();
        end
        function obj = Shape(centerX,centerY)
            obj.centerX = centerX;
            obj.centerY = centerY;
        end
    end
    methods(Abstract = true)
        getarea(obj);
    end
    methods(Static)
        function d = distanceBetweenShapes(shape1,shape2)
            xDist = abs(shape1.centerX - shape2.centerX);
            yDist = abs(shape1.centerY - shape2.centerY);
            d = sqrt(xDist^2 + yDist^2);
        end
    end
end
```

2 In the same folder, create a class, `Square`, that is a subclass of `Shape`. Save the code as `Square.m`.

```
classdef Square < Shape
% Create a Square at coordinates center X and center Y
```

```
% with sides of length of side
    properties
        side;
    end
    methods
        function obj = Square(side,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.side = side;
        end
        function Area = getarea(obj)
            Area = obj.side^2;
        end
    end
end
```

3 In the same folder, create a class, `Rhombus`, that is a subclass of `Shape`. Save the code as `Rhombus.m`.

```
classdef Rhombus < Shape
    properties
        diag1;
        diag2;
    end
    methods
        function obj = Rhombus(diag1,diag2,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.diag1 = diag1;
            obj.diag2 = diag2;
        end
        function Area = getarea(obj)
            Area = 0.5*obj.diag1*obj.diag2;
        end
    end
end
```

4 Write a function that uses this class.

```
function [TotalArea, Distance] =   use_shape
%#codegen
s = Square(2,1,2);
r = Rhombus(3,4,7,10);
TotalArea  = s.area + r.area;
Distance = Shape.distanceBetweenShapes(s,r);
```

5 Generate a static library for `use_shape` and generate a code generation report.

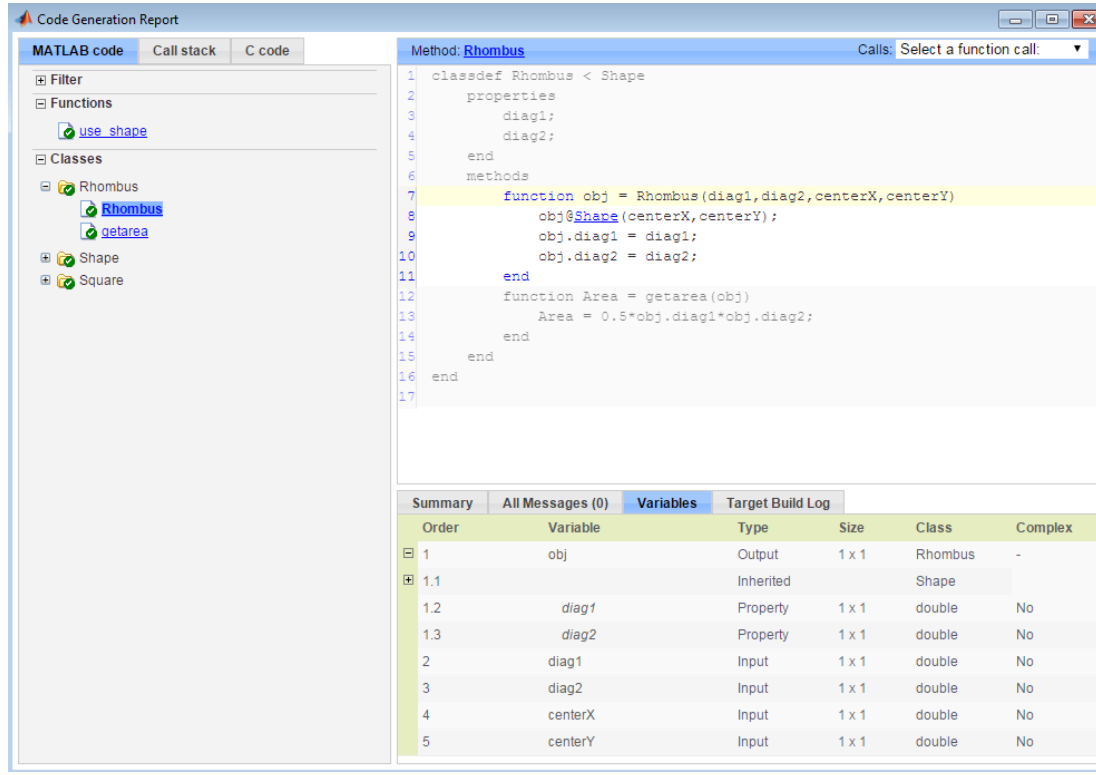
```
codegen -config:lib -report use_shape
```

`codegen` generates a C static library with the default name, `use_shape`, and supporting files in the default folder, `codegen/lib/use_shape`.

6 Click the **View report** link.

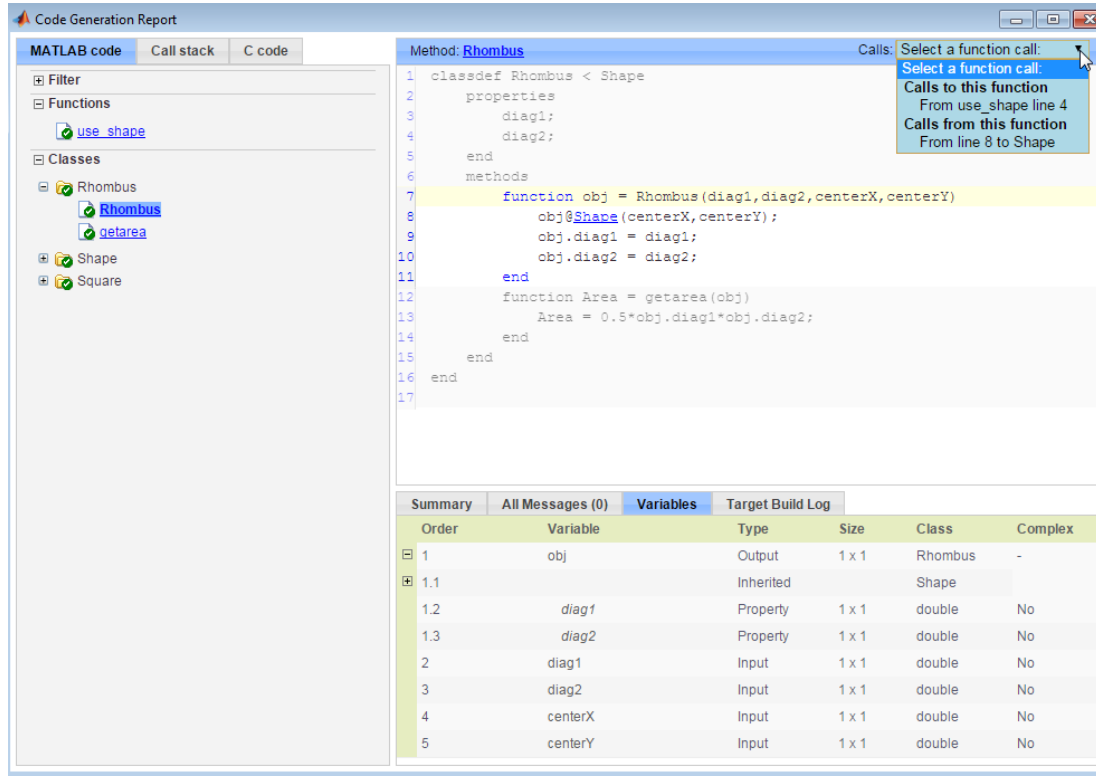
7 In the report, on the **MATLAB code** tab, click the link to the `Rhombus` class.

The report displays the class definition of the `Rhombus` class and highlights the class constructor. On the **Variables** tab, it provides details of the variables used in the class. If a variable is a MATLAB object, by default, the report displays the object without displaying its properties. To view the list of properties, expand the list. Within the list of properties, the list of inherited properties is collapsed. In the following report, the lists of properties and inherited properties are expanded.



8 At the top right side of the report, expand the **Calls** list.

The **Calls** list shows that there is a call to the `Rhombus` constructor from `use_shape` and that this constructor calls the `Shape` constructor.



9 The constructor for the `Rhombus` class calls the `Shape` method of the base `Shape` class: `obj@Shape`. In the report, click the `Shape` link in this call.

The link takes you to the `Shape` method in the `Shape` class definition.

Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

1. In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

  methods (Access=protected)
    % stepImpl method is called by the step method
    function y = stepImpl(~,x)
      y = x+1;
    end
  end
end
```

2. Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
  p = AddOne();
  y = p.step(x);
end
```

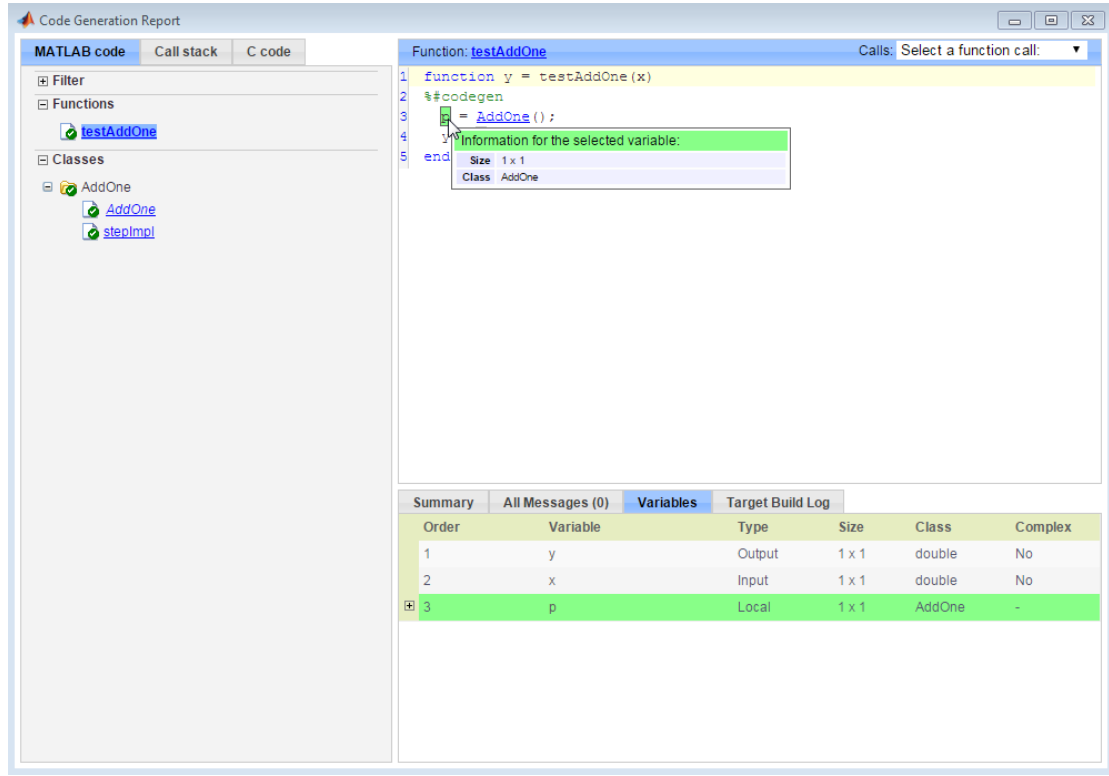
3. Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

   The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

4. Click the **View report** link.

5. In the report, on the **MATLAB Code** tab **Functions** panel, click `testAddOne`, then click the **Variables** tab. You can view information about the variable `p` on this tab.



6 To view the class definition, on the **Classes** panel, click `AddOne`.

MATLAB Classes in Code Generation Reports

What Reports Tell You About Classes

Code generation reports:

- Provide a hierarchical tree of the classes used in your MATLAB code.
- Display a list of methods for each class in the MATLAB code tab.
- Display the objects used in your MATLAB code together with their properties on the **Variables** tab.
- Provide a filter so that you can sort methods by class, size, and complexity.
- List the set of calls from and to the selected method in the **Calls** list.

How Classes Appear in Code Generation Reports

In the MATLAB Code Tab

The report displays an alphabetical hierarchical list of the classes used in the your MATLAB code. For each class, you can:

- Expand the class information to view the class methods.
- View a class method by clicking its name. The report displays the methods in the context of the full class definition.
- Filter the methods by size, complexity, and class by using the **Filter functions and methods** option.

Default Constructors

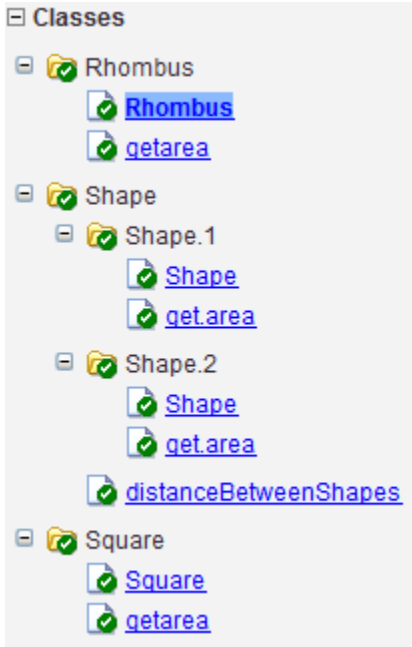
If a class has a default constructor, the report displays the constructor in italics.

Specializations

If the same class is specialized into multiple different classes, the report differentiates the specializations by grouping each one under a single node in the tree. The report associates the class definition functions and static methods with the primary node. It associates the instance-specific methods with the corresponding specialized node.

For example, consider a base class, `Shape` that has two specialized subclasses, `Rhombus` and `Square`. The `Shape` class has an abstract method, `getarea`, and a static method, `distanceBetweenShapes`. The code generation report, displays a

node for the specialized `Rhombus` and `Square` classes with their constructors and `getarea` method. It displays a node for the Shape class and its associated static method, `distanceBetweenShapes`, and two instances of the `Shape` class, `Shape1` and `Shape2`.



Packages

If you define classes as part of a package, the report displays the package in the list of classes. You can expand the package to view the classes that it contains. For more information about packages, see "Packages Create Namespaces".

In the Variables Tab

The report displays the objects in the selected function or class. By default, for classes that have properties, the list of properties is collapsed. To expand the list, click the + symbol next to the object name. Within the list of properties, the list of inherited properties is collapsed. To expand the list of inherited properties, click the + symbol next to `Inherited`.

The report displays the properties using just the base property name, not the fully qualified name. For example, if your code uses variable `obj1` that is a MATLAB object

with property `prop1`, then the report displays the property as `prop1` not `obj1.prop1`. When you sort the **Variables** column, the sort order is based on the fully qualified property name.

In the Call Stack

The call stack lists the functions and methods in the order that the top-level function calls them. It also lists the local functions that each function calls.

Troubleshooting Issues with MATLAB Classes

Class *`class`* does not have a property with name *`name`*

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
  properties
    myprop
  end
  methods
    function this = MyClass
      this.myprop = MyClass2;
    end
    function y = mymethod(this)
      y = this.myprop;
    end
  end
end

classdef MyClass2 < handle
  properties
    aa
  end
end
```

You cannot generate code for function `foo`.

```
function foo

h = MyClass;

h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

Workaround

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo

h = MyClass;

b=h.mymethod();
b.aa=12;
```

Handle Object Limitations for Code Generation

The code generation software statically determines the lifetimes of handle objects. It can reuse memory rather than rely on a dynamic memory management scheme such as reference counting or garbage collection. It generates code that does not use dynamic memory allocation or incur the overhead of run-time automatic memory management. These characteristics of the generated code are important for some safety-critical and real-time applications.

When you use handle objects, the static analysis that the code generation software uses requires that you adhere to the following restrictions:

- "A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop" on page 52-22
- "A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object" on page 52-22

A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`. The code generation software reports an error because `p`, which is outside the loop, has a property that refers to a `mycls` object created inside the loop.

```
classdef mycls < handle
   properties
       prop
   end
end

function usehandle1
p = mycls;
for i = 1:10
    p.prop = mycls;
end
```

A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generation software allows only one instance of the object during the program's lifetime. The object must be a *singleton*

object. To create a singleton handle object, enclose statements that create the object in the `if isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generation software reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
   properties
       prop
   end
end

function usehandle2(x)
assert(isa(x, 'double'));
persistent p;
inner = mycls;
inner.prop = x;
if isempty(p)
    p = mycls;
    p.prop = inner;
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `if isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
assert(isa(x, 'double'));
persistent p;
if isempty(p)
    inner = mycls;
    inner.prop = x;
    p = mycls;
    p.prop = inner;
end
```

Consider the function `usehandle3`. The code generation software reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
```

```
assert(isa(x, 'double'));
myobj = mycls;
myobj.prop = x;
doinit(myobj);
disp(myobj.prop);
function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```
function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
  myobj = mycls;
end

doinit(myobj);

function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

System Objects Requirements and Limitations for Code Generation

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty( )`.
- Set arguments to System object constructors as compile-time constants.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

Inputs and Outputs

- System objects accept a maximum of 32 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

Note: Variable-size properties in `MATLAB Function` block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

- Do not set System objects to become outputs from the `MATLAB Function` block.
- Do not use the Save and Restore Simulation State as SimState option for any System object in a `MATLAB Function` block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
  - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
  - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- Objects cannot be used as default values for properties.

Global Variables

- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the `MATLAB System` block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

  ```
  f = coder.MEXConfig;
  f.GlobalSyncMethod = 'NoSync'
  ```
  Then, include `'-config f'` in your `codegen` command.

Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define,

Code generation support is available only for these methods:

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `infoImpl`
- `isDoneImpl`
- `isInputDirectFeedThroughImpl`
- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

- Code generation support for using dot notation depends on whether the System object is predefined in the software or is one that you defined.
  - For System objects that are predefined in the software, you cannot use dot notation to call methods.
  - For System objects that you define, you can use dot notation or function call notation, with the System object as first argument, to call methods.

Code Generation for Function Handles

- "Function Handle Definition for Code Generation" on page 53-2
- "Define and Pass Function Handles for Code Generation" on page 53-3
- "Function Handle Limitations for Code Generation" on page 53-5

Function Handle Definition for Code Generation

You can use function handles to invoke functions indirectly and parameterize operations that you repeat frequently. You can perform the following operations with function handles:

- Define handles that reference user-defined functions and built-in functions supported for code generation (see "Functions and Objects Supported for C and C++ Code Generation — Alphabetical List" on page 44-2)

  Note: You cannot define handles that reference extrinsic MATLAB functions.

- Define function handles as scalar values
- Define structures that contain function handles
- Pass function handles as arguments to other functions (excluding extrinsic functions)

More About

- "Function Handle Limitations for Code Generation" on page 53-5

Define and Pass Function Handles for Code Generation

This example shows how to define and pass function handles for code generation.

Write this MATLAB code.

```
function addval(m)
%#codegen

% Pass function handle for addone
%  to add one to each element of m
m = map(@addone, m);
disp(m);

% Pass function handle for addtwo
%  to add two to each element of m
m = map(@addtwo, m);
disp(m);

function y = map(f,y)
for i = 1:numel(y)
    y(i) = f(y(i));
end

function y = addone(u)
y = u + 1;

function y = addtwo(u)
y = u + 2;
```

The function `addone` adds 1 to the value of the input. The function `addtwo` adds 2 to the value of the input. The function `map` invokes the function whose handle is stored in `f`. It invokes the function for each element of the input matrix. To add 1 to each element of its input matrix, the function `addval` passes the function handle `@addone` to `map`. To add 2 to each element of the input matrix, `addval` passes the function handle `@addtwo` to `map`.

Define a 3-by-3 matrix `m`.

```
m = zeros(3);
```

Run `addval` in MATLAB. Pass `m` as the input argument.

```
addval(m)
```

```
     1     1     1
     1     1     1
     1     1     1

     3     3     3
     3     3     3
     3     3     3
```

Generate a MEX function for `addval`. Specify that the input argument has the class and size of the MATLAB variable `m`.

```
codegen addval -args {m} -report
```

Run the MEX function.

```
addval_mex(m)
```

```
     1     1     1
     1     1     1
     1     1     1

     3     3     3
     3     3     3
     3     3     3
```

The output is the same as the output from running `addval` in MATLAB.

More About

- "Function Handle Definition for Code Generation" on page 53-2
- "Function Handle Limitations for Code Generation" on page 53-5

Function Handle Limitations for Code Generation

Do not use the same bound variable to reference different function handles

In some cases, using the same bound variable to reference different function handles causes a compile-time error. For example, this code does not compile:

```
function y = foo(p)
x = @plus;
if p
  x = @minus;
end
y = x(1, 2);
```

Do not pass function handles to or from `coder.ceval`

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

Do not pass function handles to or from extrinsic functions

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions. For more information, see “Declaring MATLAB Functions as Extrinsic Functions” on page 55-12.

Do not pass function handles to or from primary functions

You cannot pass function handles as inputs to or outputs from primary functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle,'function_handle') && isa(data,'double'));
```

```
plot(data, fhandle(data));
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as primary inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of primary inputs.

Do not try to view function handles from the debugger

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

Defining Functions for Code Generation

- "Specify Variable Numbers of Arguments" on page 54-2
- "Supported Index Expressions" on page 54-3
- "Apply Operations to a Variable Number of Arguments" on page 54-4
- "Implement Wrapper Functions" on page 54-6
- "Variable Length Argument Lists for Code Generation" on page 54-7

Specify Variable Numbers of Arguments

You can use `varargin` in a function definition to specify that the function accepts a variable number of input arguments for a given input argument. You can use `varargout` in a function definition to specify that the function returns a variable number of arguments for a given output argument.

When you use `varargin` and `varargout` for code generation, there are the following limitations:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a `MATLAB Function` block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generation software generates the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

Common applications of `varargin` and `varargout` for code generation are to:

- "Apply Operations to a Variable Number of Arguments" on page 54-4
- "Implement Wrapper Functions" on page 54-6
- Pass property/value pairs

Code generation relies on loop unrolling to produce simple and efficient code for `varargin` and `varargout`. This technique permits most common uses of `varargin` and `varargout`, but some uses are not allowed (see "Variable Length Argument Lists for Code Generation" on page 54-7).

For more information about using `varargin` and `varargout` in MATLAB functions, see Passing Variable Numbers of Arguments.

Supported Index Expressions

In MATLAB, `varargin` and `varargout` are cell arrays. For code generation, to index `varargin` and `varargout`, you must use a syntax that code generation supports. You can use the most common syntax — curly braces `{}`. For example:

```
%#codegen
function [x,y,z] = fcn(a,b,c)
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
for i = 1:length(varargin)
   varargout{i} = varargin{i};
end
```

You can use the following index expressions. The *exp* arguments must be constant expressions or depend on a loop index variable.

Expression		Description
`varargin` *(read only)*	`varargin{`*exp*`}`	Read the value of element *exp*
	`varargin{`*exp1*`:` *exp2*`}`	Read the values of elements *exp1* through *exp2*
	`varargin{:}`	Read the values of all elements
`varargout` *(read and write)*	`varargout{`*exp*`}`	Read or write the value of element *exp*

Note: The use of `()` is not supported for indexing into `varargin` and `varargout` arrays.

Apply Operations to a Variable Number of Arguments

You can use `varargin` and `varargout` in `for`-loops to apply operations to a variable number of arguments. To index into `varargin` and `varargout` arrays in generated code, the value of the loop index variable must be known at compile time. Therefore, during code generation, the compiler attempts to automatically unroll these `for`-loops. Unrolling eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant. For example, the following function automatically unrolls its `for`-loop in the generated code:

```
%#codegen
function [cmlen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmlen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
   varargout{i} = varargin{i} * 2.54;
end
```

When to Force Loop Unrolling

To automatically unroll `for`-loops containing `varargin` and `varargout` expressions, the relationship between the loop index expression and the index variable must be determined at compile time.

In the following example, the function `fcn` cannot detect a logical relationship between the index expression `j` and the index variable `i`:

```
%#codegen
function [x,y,z] = fcn(a,b,c)

[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
j = 0;
for i = 1:length(varargin)
    j = j+1;
    varargout{j} = varargin{j};
end
```

As a result, the function does not unroll the loop and generates a compilation error:

```
Nonconstant expression or empty matrix.
This expression must be constant because
its value determines the size or class of some expression.
```

To fix the problem, you can force loop unrolling by wrapping the loop header in the function `coder.unroll`, as follows:

```
%#codegen
function [x,y,z] = fcn(a,b,c)
  [x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
  j = 0;
  for i = coder.unroll(1:length(varargin))
      j = j + 1;
      varargout{j} = varargin{j};
  end;
```

Using Variable Numbers of Arguments in a for-Loop

The following example multiplies a variable number of input dimensions in inches by 2.54 to convert them to centimeters:

```
%#codegen
function [cmlen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmlen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
   varargout{i} = varargin{i} * 2.54;
end
```

Key Points About the Example

- `varargin` and `varargout` appear in the local function `inch_2_cm`, not in the top-level function `conv_2_metric`.
- The index into `varargin` and `varargout` is a for-loop variable

For more information, see “Variable Length Argument Lists for Code Generation” on page 54-7.

Implement Wrapper Functions

You can use `varargin` and `varargout` to write wrapper functions that accept up to 64 inputs and pass them directly to another function.

Passing Variable Numbers of Arguments from One Function to Another

The following example passes a variable number of inputs to different optimization functions, based on a specified input method:

```
%#codegen
function answer = fcn(method,a,b,c)
answer = optimize(method,a,b,c);

function answer = optimize(method,varargin)
  if strcmp(method,'simple')
    answer = simple_optimization(varargin{:});
  else
    answer = complex_optimization(varargin{:});
  end
...
```

Key Points About the Example

- You can use `{:}` to read all elements of `varargin` and pass them to another function.
- You can mix variable and fixed numbers of arguments.

For more information, see “Variable Length Argument Lists for Code Generation” on page 54-7.

Variable Length Argument Lists for Code Generation

Use variable length argument lists in top-level functions according to guidelines

When you use `varargin` and `varargout` for code generation, there are the following limitations:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a `MATLAB Function` block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generation software generates the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

A *top-level function* is:

- The function called by Simulink in a `MATLAB Function` block or by Stateflow in a MATLAB function.
- The function that you provide on the command line to `codegen` or `fiaccel`.

For example, the following code generates compilation errors:

```
%#codegen
function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
   varargout{i} = varargin{i} * 2.54;
end
```

To fix the problem, write a top-level function that specifies a fixed number of inputs and outputs. Then call `inch_2_cm` as an external function or local function, as in this example:

```
%#codegen
function [cmL, cmW, cmH] = conv_2_metric(inL, inW, inH)
[cmL, cmW, cmH] = inch_2_cm(inL, inW, inH);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
   varargout{i} = varargin{i} * 2.54;
end
```

Use curly braces {} to index into the argument list

For code generation, you can use curly braces `{}`, but not parentheses `()`, to index into `varargin` and `varargout` arrays. For more information, see "Supported Index Expressions" on page 54-3.

Verify that indices can be computed at compile time

If you use an expression to index into `varargin` or `varargout`, make sure that the value of the expression can be computed at compile time. For examples, see "Apply Operations to a Variable Number of Arguments" on page 54-4.

Do not write to varargin

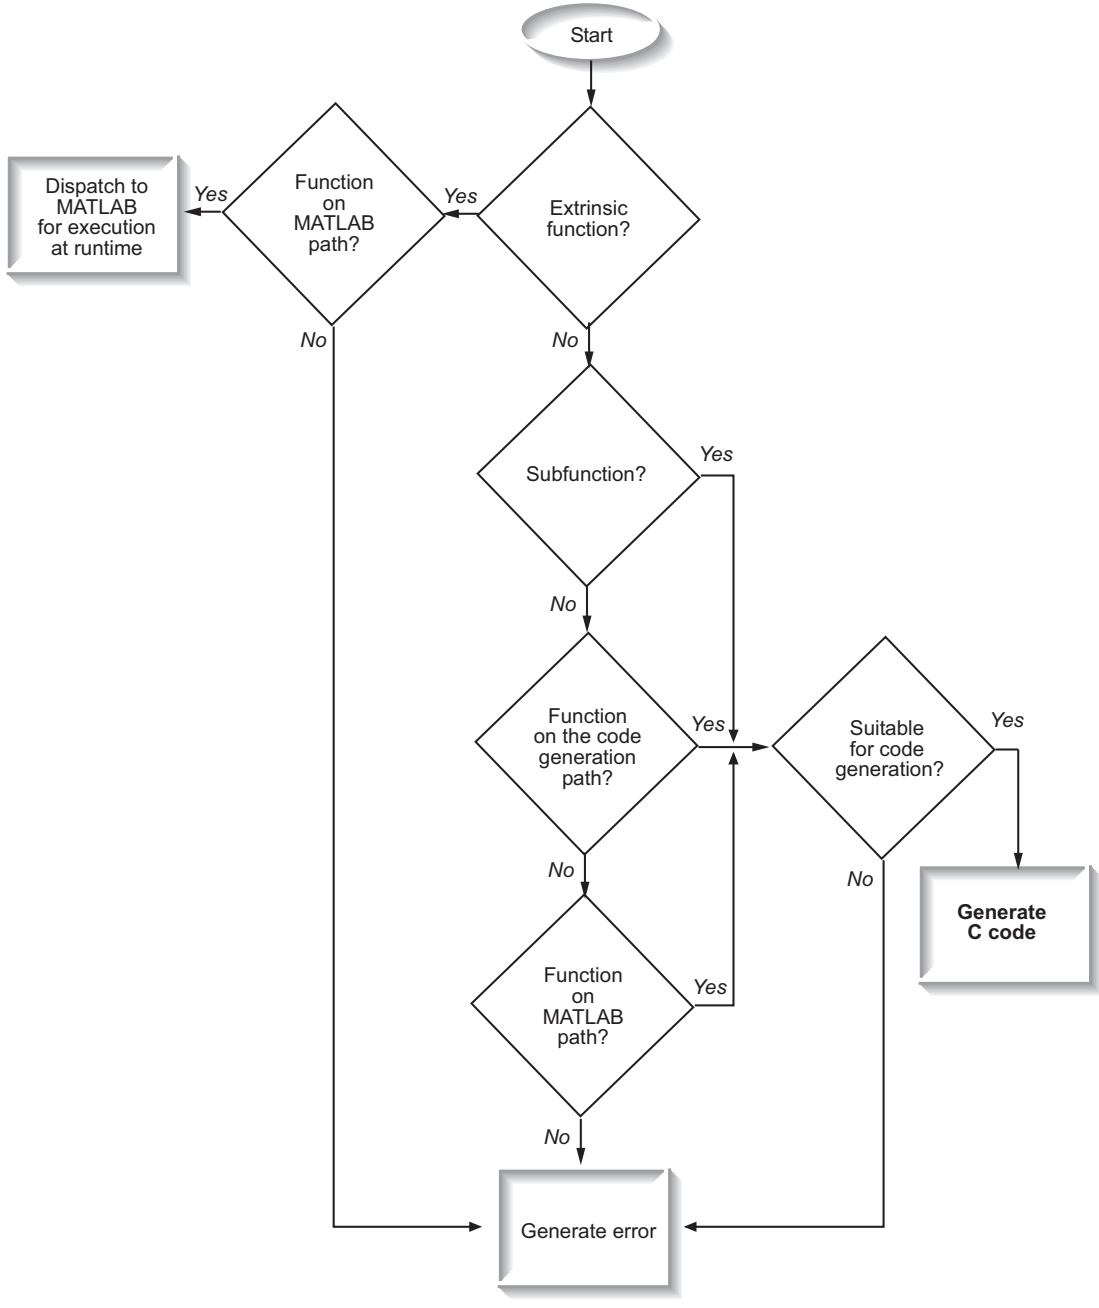
Generated code treats `varargin` as a read-only variable. If you want to write to input arguments, copy the values into a local variable.

Calling Functions for Code Generation

- "Resolution of Function Calls for Code Generation" on page 55-2
- "Resolution of File Types on Code Generation Path" on page 55-6
- "Compilation Directive %#codegen" on page 55-8
- "Call Local Functions" on page 55-9
- "Call Supported Toolbox Functions" on page 55-10
- "Call MATLAB Functions" on page 55-11

Resolution of Function Calls for Code Generation

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:



Start
Extrinsic function?
Yes
Function on MATLAB path?
Yes
Dispatch to MATLAB for execution at runtime
No
No
Subfunction?
Yes
No
Function on the code generation path?
Yes
Suitable for code generation?
Yes
No
Generate C code
No
Function on MATLAB path?
Yes
No
Generate error

Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path

  See "Compile Path Search Order" on page 55-4.

- Attempts to compile functions unless the code generation software determines that it should not compile them or you explicitly declare them to be extrinsic.

  If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in "Declaring MATLAB Functions as Extrinsic Functions" on page 55-12. During simulation, the code generation software generates code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, the code generation software attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, compilation errors occur.

  The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.

- Resolves file type based on precedence rules described in "Resolution of File Types on Code Generation Path" on page 55-6

Compile Path Search Order

During code generation, function calls are resolved on two paths:

1. Code generation path

   MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.

2. MATLAB path

If the function is not on the code generation path, MATLAB searches this path.

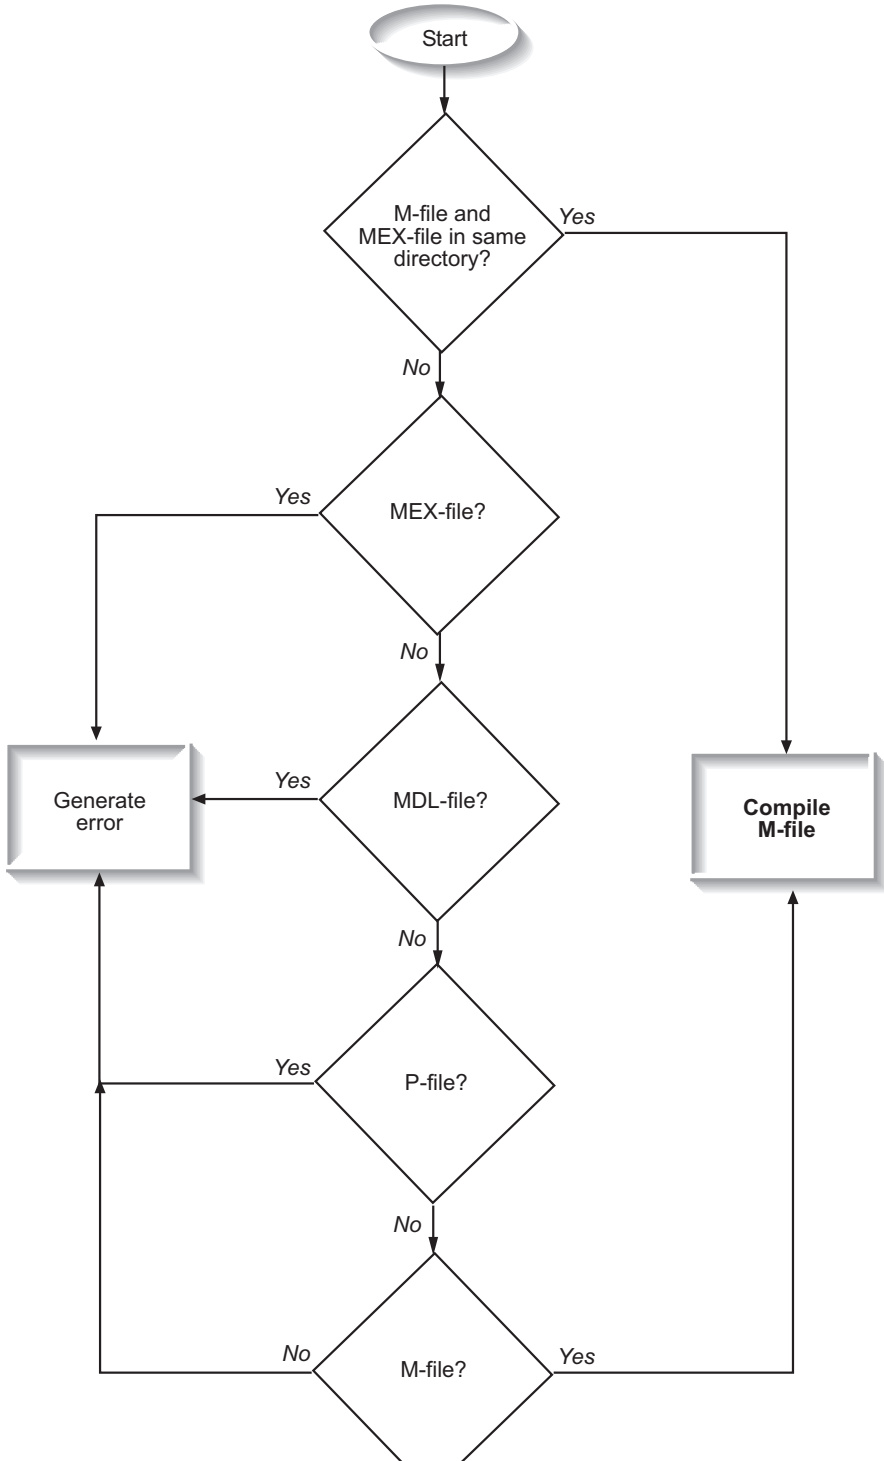
MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order”).

When to Use the Code Generation Path

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

Resolution of File Types on Code Generation Path

MATLAB uses the following precedence rules for code generation:



Start
M-file and MEX-file in same directory?
Yes
No
MEX-file?
Yes
No
MDL-file?
Yes
Generate error
No
P-file?
Yes
No
M-file?
No
Yes
Compile M-file

Compilation Directive %#codegen

Add the `%#codegen` directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB code analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen

....
```

Call Local Functions

Local functions are functions defined in the body of MATLAB function. They work the same way for code generation as they do when executing your algorithm in the MATLAB environment.

The following example illustrates how to define and call a local function `mean`:

```
function [mean, stdev] = stats(vals)
%#codegen

% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals, len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

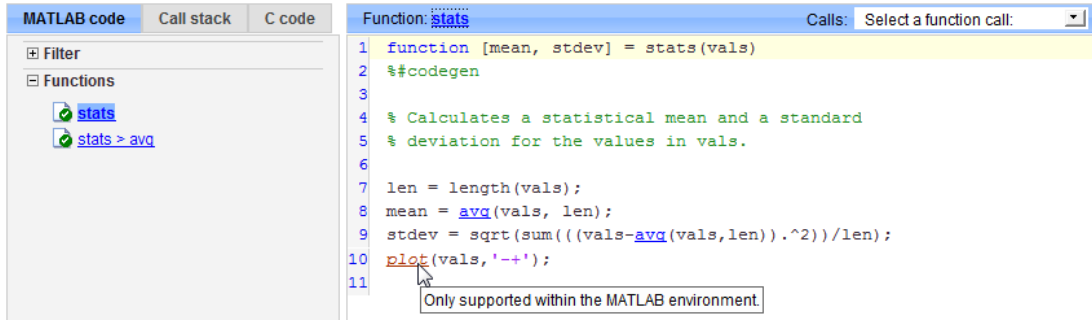
Call Supported Toolbox Functions

You can call toolbox functions directly if they are supported for code generation. For a list of supported functions, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 44-2.

Call MATLAB Functions

The code generation software attempts to generate code for functions, even if they are not supported for C code generation. The software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using `coder.extrinsic`. During simulation, the code generation software generates code for these functions, but does not generate their internal code. During standalone code generation, the code generation software attempts to determine whether the visualization function affects the output of the function in which it is called. Provided that the output does not change, the code generation software proceeds with code generation, but excludes the visualization function from the generated code. Otherwise, compilation errors occur.

For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot` and then run the generated MEX function, the code generation software dispatches calls to the `plot` function to MATLAB. If you generate a library or executable, the generated code does not contain calls to the `plot` function. The code generation report highlights calls from your MATLAB code to extrinsic functions so that it is easy to determine which functions are supported only in the MATLAB environment.



For unsupported functions other than common visualization functions, you must declare the functions to be extrinsic (see “Resolution of Function Calls for Code Generation” on page 55-2). Extrinsic functions are not compiled, but instead executed in MATLAB during simulation (see “Resolution of Extrinsic Functions During Simulation” on page 55-16).

There are two ways to declare a function to be extrinsic:

- Use the `coder.extrinsic` construct in main functions or local functions (see "Declaring MATLAB Functions as Extrinsic Functions" on page 55-12).
- Call the function indirectly using `feval` (see "Calling MATLAB Functions Using feval" on page 55-16).

Declaring MATLAB Functions as Extrinsic Functions

To declare a MATLAB function to be extrinsic, add the `coder.extrinsic` construct at the top of the main function or a local function:

```
coder.extrinsic('function_name_1', ... , 'function_name_n');
```

Declaring Extrinsic Functions

The following code declares the MATLAB `patch` function extrinsic in the local function `create_plot`. You do not have to declare `axis` as extrinsic because `axis` is one of the common visualization functions that the code generation software automatically treats as extrinsic.

```
function c = pythagoras(a,b,color) %#codegen
% Calculates the hypotenuse of a right triangle
%  and displays the triangle.

c = sqrt(a^2 + b^2);
create_plot(a, b, color);

function create_plot(a, b, color)
%Declare patch as extrinsic

coder.extrinsic('patch');

x = [0;a;a];
y = [0;0;b];
patch(x, y, color);
axis('equal');
```

The code generation software does not generate code for `patch` and `axis`, but instead dispatches them to MATLAB for execution.

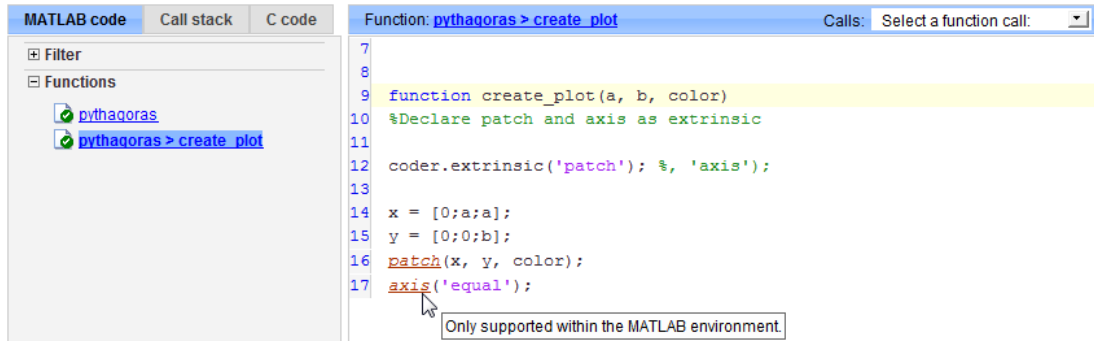
To test the function, follow these steps:

1. Convert `pythagoras` to a MEX function by executing this command at the MATLAB prompt:

   ```
   codegen -report pythagoras -args {1, 1, [.3 .3 .3]}
   ```

2. Click the link to the code generation report and then, in the report, view the MATLAB code for `create_plot`.

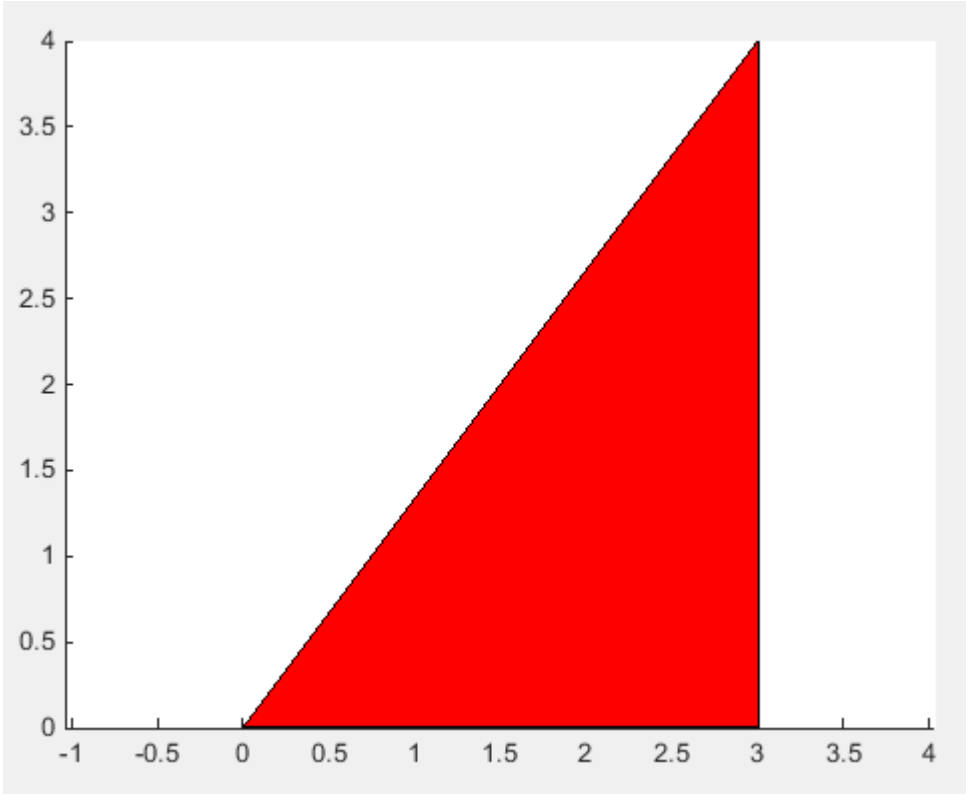
   The report highlights the `patch` and `axis` functions to indicate that they are supported only within the MATLAB environment.



3. Run the MEX function by executing this command:

   ```
   pythagoras_mex(3, 4, [1.0 0.0 0.0]);
   ```

   MATLAB displays a plot of the right triangle as a red patch object:



When to Use the coder.extrinsic Construct

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output during simulation, without generating unnecessary code (see "Resolution of Extrinsic Functions During Simulation" on page 55-16).
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays` (see "Working with mxArrays" on page 55-17).

- Save typing. With one `coder.extrinsic` statement, each subsequent function call is extrinsic, as long as the call and the statement are in the same scope (see "Scope of Extrinsic Function Declarations" on page 55-15).
- Declare the MATLAB function(s) extrinsic throughout the calling function scope (see "Scope of Extrinsic Function Declarations" on page 55-15). To narrow the scope, use `feval` (see "Calling MATLAB Functions Using feval" on page 55-16).

Rules for Extrinsic Function Declarations

Observe the following rules when declaring functions extrinsic for code generation:

- Declare the function extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.

Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` as treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

  ```
  function y = foo %#codegen
  coder.extrinsic('rat');
  [N D] = rat(pi);
  y = 0;
  y = mymin(N, D);

  function y = mymin(a,b)
  coder.extrinsic('min');
  y = min(a,b);
  ```

  Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.

- Call the MATLAB function using `feval`, as described in "Calling MATLAB Functions Using feval" on page 55-16.

Calling MATLAB Functions Using feval

The function `feval` is automatically interpreted as an extrinsic function during code generation. Therefore, you can use `feval` to conveniently call functions that you want to execute in the MATLAB environment, rather than compiled to generated code.

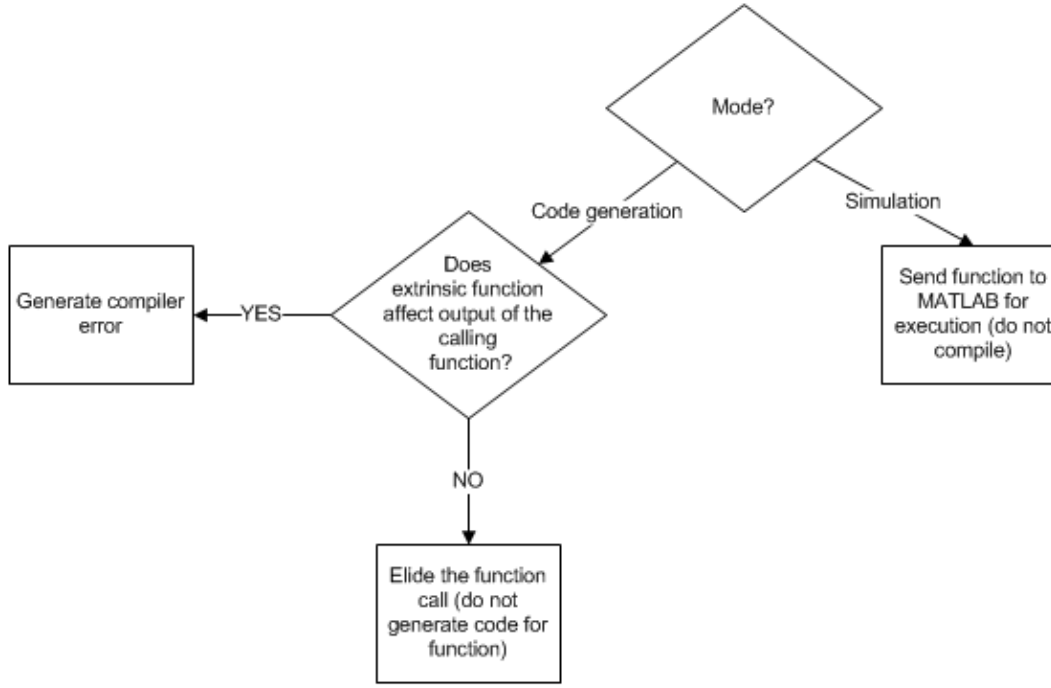
Consider the following example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min', N, D);
```

Because `feval` is extrinsic, the statement `feval('min', N, D)` is evaluated by MATLAB — not compiled — which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

Resolution of Extrinsic Functions During Simulation

The code generation software resolves calls to extrinsic functions — functions that do not support code generation — as follows:



During simulation, the code generation software generates code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, you can run the simulation only on platforms where you install MATLAB software.

During code generation, the code generation software attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable (see "Working with mxArrays" on page 55-17). Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, the code generation software issues a compiler error.

Working with mxArrays

The output of an extrinsic function is an `mxArray` — also called a MATLAB array. The only valid operations for `mxArrays` are:

- Storing `mxArrays` in variables

- Passing `mxArrays` to functions and returning them from functions
- Converting `mxArrays` to known types at run time

To use `mxArrays` returned by extrinsic functions in other operations, you must first convert them to known types, as described in "Converting mxArrays to Known Types" on page 55-18.

Converting mxArrays to Known Types

To convert an `mxArray` to a known type, assign the `mxArray` to a variable whose type is defined. At run time, the `mxArray` is converted to the type of the variable assigned to it. However, if the data in the `mxArray` is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N, D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two `mxArrays` representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. Although you can pass these `mxArrays` to another MATLAB function — in this case, `min` — you cannot assign the `mxArray` returned by `min` to the output `y`.

If you run this function `foo` in a MATLAB Function block in a Simulink model, the code generates the following error during simulation:

```
Function output 'y' cannot be of MATLAB type.
```

To fix this problem, define `y` to be the type and size of the value that you expect `min` to return — in this case, a scalar double — as follows:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

Restrictions on Extrinsic Functions for Code Generation

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller workspace do not work during code generation. Such functions include:
  - `dbstack`
  - `evalin`
  - `assignin`
  - `save`
- The MATLAB debugger cannot inspect variables defined in extrinsic functions.
- Functions in generated code can produce unpredictable results if your extrinsic function performs the following actions at run time:
  - Change folders
  - Change the MATLAB path
  - Delete or add MATLAB files
  - Change warning states
  - Change MATLAB preferences
  - Change Simulink parameters

Limit on Function Arguments

You can call functions with up to 64 inputs and 64 outputs.

Optimization Strategies

MATLAB Coder introduces certain optimizations when generating `C/C++` code or `MEX` functions from your MATLAB code. For more information, see "MATLAB Coder Optimizations in Generated Code".

To optimize your generated code further, you can:

- Adapt your MATLAB code.
- Control code generation using the configuration object from the command-line or the project settings dialog box.

To optimize the execution speed of generated code, for these conditions, perform the following actions as necessary:

Condition	Action
You have `for`-loops whose iterations are independent of each other.	"Generate Code with Parallel for-Loops (parfor)"
You have variable-size arrays in your MATLAB code.	"Minimize Dynamic Memory Allocation"
You have multiple variable-size arrays in your MATLAB code. You want dynamic memory allocation for larger arrays and static allocation for smaller ones.	"Set Dynamic Memory Allocation Threshold"
You want your generated function to be called by reference.	"Eliminate Redundant Copies of Function Inputs"
You are calling small functions in your MATLAB code.	"Inline Code"
You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.	"Control Inlining"
You do not want to generate code for expressions that contain constants only.	"Fold Function Calls into Constants"
You have loop operations in your MATLAB code that do not depend on the loop index.	"Minimize Redundant Operations in Loops"

Condition	Action
You have integer operations in your MATLAB code. You know beforehand that integer overflow does not occur during execution of your generated code.	"Disable Support for Integer Overflow"
You know beforehand that `Inf`s and `NaN`s do not occur during execution of your generated code.	"Disable Support for Non-Finite Numbers"
You have `for`-loops with few iterations.	"Unroll for-Loops"
You already have legacy C/C++ code optimized for your target environment.	"Integrate External/Custom Code"
You want to speed up the code generated for linear algebra functions.	"Speed Up Linear Algebra in Generated Standalone Code by Using LAPACK Calls"

To optimize the memory usage of generated code, for these conditions, perform the following actions as necessary:

Condition	Action
You have `if/else/elseif` statements or `switch/case/otherwise` statements in your MATLAB code. You do not require some branches of the statements in your generated code.	"Prevent Code Generation for Unused Execution Paths"
You want your generated function to be called by reference.	"Eliminate Redundant Copies of Function Inputs"
You have limited stack space for your generated code.	"Control Stack Space Usage"
You are calling small functions in your MATLAB code.	"Inline Code"
You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.	"Control Inlining"
You do not want to generate code for expressions that contain constants only.	"Fold Function Calls into Constants"

Condition	Action
You have loop operations in your MATLAB code that do not depend on the loop index.	"Minimize Redundant Operations in Loops"
You have integer operations in your MATLAB code. You know beforehand that integer overflow does not occur during execution of your generated code.	"Disable Support for Integer Overflow"
You know beforehand that `Inf`-s and `NaN`-s does not occur during execution of your generated code.	"Disable Support for Non-Finite Numbers"
Your MATLAB code has variables that are large arrays or structures. The variable reuse optimization preserves your variable names. You want to see if the extra memory required to preserve the variable names of the large arrays or structures affects performance.	"Reuse Large Arrays and Structures"

Modularize MATLAB Code

For large MATLAB code, streamline code generation by modularizing the code:

1. Break up your MATLAB code into smaller, self-contained sections.
2. Save each section in a MATLAB function.
3. Generate C/C++ code for each function.
4. Call the generated C/C++ functions in sequence from a wrapper MATLAB function using `coder.ceval`.
5. Generate C/C++ code for the wrapper function.

Besides streamlining code generation for the original MATLAB code, this approach also supplies you with C/C++ code for the individual sections. You can reuse the code for the individual sections later by integrating them with other generated C/C++ code using `coder.ceval`.

Eliminate Redundant Copies of Function Inputs

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input `A` is passed by reference in the generated code because it also acts as an output for function `foo`:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
    *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function `foo` without the optimization:

```
function y = foo2( A, B ) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
   return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
  x1=u1+1;
  y1=bar(x1);
end

function y2=bar(u2)
  % Since foo does not use x1 later in the function,
  % it would be optimal to do this operation in place
  x2=u2.*2;
  % The change in dimensions in the following code
  % means that it cannot be done in place
  y2=[x2,x2];
end
```

You can modify this code to eliminate redundant copies.

```
function y1=foo(u1) %#codegen
  u1=u1+1;
  [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
    u2=u2.*2;
  % The change in dimensions in the following code
  % still means that it cannot be done in place
  y2=[u2,u2];
end
```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generation software treats the output as a separate variable. For example, consider the function `foo`:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

Generate code in which `A` has a constant value `2`.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant A and returns the value of the output.

```
...
#define A                              (2.0)
...
double foo(double B)
{
  return A * B;
}
...
```

Inline Code

Inlining is a technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C ++ code. Inlining can create opportunities for further optimization of the generated C/C ++ code. The code generation software uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

In this section...

"Prevent Function Inlining" on page 56-9

"Use Inlining in Control Flow Statements" on page 56-9

Prevent Function Inlining

In this example, function `foo` is not inlined in the generated code:

```
function y = foo(x)
  coder.inline('never');
  y = x;
end
```

Use Inlining in Control Flow Statements

You can use `coder.inline` in control flow code. If the software detects contradictory `coder.inline` directives, the generated code uses the default inlining heuristic and issues a warning.

Suppose you want to generate code for a division function that will be embedded in a system with limited memory. To optimize memory use in the generated code, the following function, `inline_division`, manually controls inlining based on whether it performs scalar division or vector division:

```
function y = inline_division(dividend, divisor)

% For scalar division, inlining produces smaller code
% than the function call itself.
if isscalar(dividend) && isscalar(divisor)
   coder.inline('always');
else
```

```
% Vector division produces a for-loop.
% Prohibit inlining to reduce code size.
   coder.inline('never');
end

if any(divisor == 0)
   error('Can not divide by 0');
end

y = dividend / divisor;
```

Related Examples

- "Control Inlining"

Control Inlining

Restrict inlining when:

- The size of generated code exceeds desired limits due to excessive inlining of functions. Suppose that you include the statement, `coder.inline('always')`, inside a certain function. You then call that function at many different sites in your code. The generated code can be large due to the function being inlined every time it is called.

  The call sites must be different. For instance, inlining does not lead to large code if the function to be inlined is called several times inside a loop.
- You have limited RAM or stack space.

In this section...
“Control Size of Functions Inlined” on page 56-11
“Control Size of Functions After Inlining” on page 56-12
“Control Stack Size Limit on Inlined Functions” on page 56-12

Control Size of Functions Inlined

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions that can be inlined. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThreshold`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineThreshold = 100;
  ```

  Generate code using this configuration object.

Control Size of Functions After Inlining

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions after inlining. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold max**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineThresholdMax = 100;
  ```

  Generate code using this configuration object.

Control Stack Size Limit on Inlined Functions

Specifying a limit on the stack space constrains the amount of inlining allowed. For out-of-line functions, stack space for variables local to the function is released when the function returns. However, for inlined functions, stack space remains occupied by the local variables even after the function is executed. The value of the property, `InlineStackLimit`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `InlineStackLimit` can accomodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

You can use the MATLAB Coder app or the command-line interface to control the stack size limit on inlined functions.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline stack limit**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineStackLimit = 2000;
  ```

  Generate code using this configuration object.

Related Examples

- "Inline Code"

Fold Function Calls into Constants

This example shows how to specify constants in generated code using `coder.const`. The code generation software folds an expression or a function call in a `coder.const` statement into a constant in generated code. Because the generated code does not have to evaluate the expression or call the function every time, this optimization reduces the execution time of the generated code.

Write a function `AddShift` that takes an input `Shift` and adds it to the elements of a vector. The vector consists of the square of the first 10 natural numbers. `AddShift` generates this vector.

```
function y = AddShift(Shift) %#codegen
y = (1:10).^2+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generation software generates code for creating the vector. It adds `Shift` to each element of the vector during vector creation. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
  int k;
  for (k = 0; k < 10; k++) {
    y[k] = (double)((1 + k) * (1 + k)) + Shift;
  }
}
```

Replace the statement

```
y = (1:10).^2+Shift;
```

with

```
y = coder.const((1:10).^2)+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generation software creates the vector containing the squares of the first 10 natural numbers. In the generated code, it adds `Shift` to each element of this vector. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
  int i0;
  static const signed char iv0[10] = { 1, 4, 9, 16, 25, 36,
                                       49, 64, 81, 100 };

  for (i0 = 0; i0 < 10; i0++) {
    y[i0] = (double)iv0[i0] + Shift;
  }
}
```

`coder.const`

Control Stack Space Usage

This example shows how to set the maximum stack space that the generated code uses. Set the maximum stack usage when:

- You have limited stack space, for instance, in embedded targets.
- Your C compiler reports a run-time stack overflow.

The value of the property, `StackUsageMax`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `StackUsageMax` can accomodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Control Stack Space Usage Using the MATLAB Coder App

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
2. Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
3. Click **More Settings**.
4. On the **Memory** tab, set **Stack usage max** to the value that you want.

Control Stack Space Usage at the Command Line

1. Create a configuration object for code generation.

   Use `coder.config` with arguments `'lib'`,`'dll'`, or `'exe'` (depending on your requirements). For example:

   ```
   cfg = coder.config('lib');
   ```

2. Set the property, `StackUsageMax`, to the value that you want.

   ```
   cfg.StackUsageMax=400000;
   ```

More About

- “Stack Allocation and Performance”

Stack Allocation and Performance

By default, local variables are allocated on the stack. Large variables that do not fit on the stack are statically allocated in memory.

Stack allocation typically uses memory more efficiently than static allocation. However, stack space is sometimes limited, typically in embedded processors. MATLAB Coder allows you to manually set a limit on the stack space usage to make your generated code suitable for your target hardware. You can choose this limit based on the target hardware configurations. For more information, see “Control Stack Space Usage”.

Dynamic Memory Allocation and Performance

To achieve faster execution of generated code, minimize dynamic (or run-time) memory allocation of arrays.

MATLAB Coder does not provide a size for unbounded arrays in generated code. Instead, such arrays are referenced indirectly through pointers. For such arrays, memory cannot be allocated during compilation of generated code. Based on storage requirements for the arrays, memory is allocated and freed at run time as required. This run-time allocation and freeing of memory leads to slower execution of the generated code. For more information on dynamic memory allocation, see "Bounded Versus Unbounded Variable-Size Data".

When Dynamic Memory Allocation Occurs

Dynamic memory allocation occurs when the code generation software cannot find upper bounds for variable-size arrays. The software cannot find upper bounds when you specify the size of an array using a variable that is not a compile-time constant. An example of such a variable is an input variable (or a variable computed from an input variable).

Instances in the MATLAB code that can lead to dynamic memory allocation are:

- Array initialization: You specify array size using a variable whose value is known only at run time.
- After initialization of an array:
  - You declare the array as variable-size using `coder.varsize` without explicit upper bounds. After this declaration, you expand the array by concatenation inside a loop. The number of loop runs is known only at run time.
  - You use a `reshape` function on the array. At least one of the size arguments to the `reshape` function is known only at run time.

If you know the maximum size of the array, you can avoid dynamic memory allocation. You can then provide an upper bound for the array and prevent dynamic memory allocation in generated code. For more information, see "Minimize Dynamic Memory Allocation" on page 56-19.

Minimize Dynamic Memory Allocation

When possible, minimize dynamic memory allocation because it leads to slower execution of generated code. Dynamic memory allocation occurs when the code generation software cannot find upper bounds for variable-size arrays.

If you know the maximum size of a variable-size array, you can avoid dynamic memory allocation. Follow these steps:

1. "Provide Maximum Size for Variable-Size Arrays" on page 56-20.
2. Depending on your requirements, do one of the following:
   - "Disable Dynamic Memory Allocation During Code Generation" on page 56-26.
   - "Set Dynamic Memory Allocation Threshold"

Caution If a variable-size array in the MATLAB code does not have a maximum size, disabling dynamic memory allocation leads to a code generation error. Before disabling dynamic memory allocation, you must provide a maximum size for variable-size arrays in your MATLAB code.

More About

- "Dynamic Memory Allocation and Performance"

Provide Maximum Size for Variable-Size Arrays

To constrain array size for variable-size arrays, do one of the following:

- **Constrain Array Size Using assert Statements**

  If the variable specifying array size is not a compile-time constant, use an `assert` statement with relational operators to constrain the variable. Doing so helps the code generation software to determine a maximum size for the array.

  The following examples constrain array size using `assert` statements:

  - **When Array Size Is Specified by Input Variables**

    Define a function `array_init` which initializes an array `y` with input variable `N`:

    ```
    function y = array_init (N)
      assert(N <= 25); % Generates exception if N > 25
      y = zeros(1,N);
    ```

    The `assert` statement constrains input `N` to a maximum size of 25. In the absence of the `assert` statement, `y` is assigned a pointer to an array in the generated code, thus allowing dynamic memory allocation.

  - **When Array Size Is Obtained from Computation Using Input Variables**

    Define a function, `array_init_from_prod`, which takes two input variables, `M` and `N`, and uses their product to specify the maximum size of an array, `y`.

    ```
    function y = array_init_from_prod (M,N)
       size=M*N;
       assert(size <= 25); % Generates exception if size > 25
       y=zeros(1,size);
    ```

    The `assert` statement constrains the product of `M` and `N` to a maximum of 25.

    Alternatively, if you restrict `M` and `N` individually, it leads to dynamic memory allocation:

    ```
    function y = array_init_from_prod (M,N)
       assert(M <= 5);
       assert(N <= 5);
       size=M*N;
       y=zeros(1,size);
    ```

This code causes dynamic memory allocation because `M` and `N` can both have unbounded negative values. Therefore, their product can be unbounded and positive even though, individually, their positive values are bounded.

Tip Place the assert statement on a variable immediately before it is used to specify array size.

Tip You can use `assert` statements to restrict array sizes in most cases. When expanding an array inside a loop, this strategy does not work if the number of loop runs is known only at run time.

- **Restrict Concatenations in a Loop Using coder.varsize with Upper Bounds**

  You can expand arrays beyond their initial size by concatenation. When you concatenate additional elements inside a loop, there are two syntax rules for expanding arrays.

  1. **Array size during initialization is not a compile-time constant**

     If the size of an array during initialization is not a compile-time constant, you can expand it by concatenating additional elements:

     ```
     function out=ExpandArray(in) % Expand an array by five elements
       out = zeros(1,in);
       for i=1:5
          out = [out 0];
       end
     ```

  2. **Array size during initialization is a compile-time constant**

     Before concatenating elements, you have to declare the array as variable-size using `coder.varsize`:

     ```
     function out=ExpandArray() % Expand an array by five elements
       out = zeros(1,5);
       coder.varsize('out');
       for i=1:5
          out = [out 0];
       end
     ```

Either case leads to dynamic memory allocation. To prevent dynamic memory allocation in such cases, use `coder.varsize` with explicit upper bounds. This example shows how to use `coder.varsize` with explicit upper bounds:

Restrict Concatenations Using coder.varsize with Upper Bounds

1 Define a function, `RunningAverage`, that calculates the running average of an `N`-element subset of an array:

```
function avg=RunningAverage(N)

% Array whose elements are to be averaged
  NumArray=[1 6 8 2 5 3];

% Initialize average:
% These will also be the first two elements of the function output
  avg=[0 0];

% Place a bound on the argument
  coder.varsize('avg',[1 8]);

% Loop to calculate running average
  for i=1:N
    s=0;
    s=s+sum(NumArray(1:i));
    avg=[avg s/i];
  % Increase the size of avg as required by concatenation
  end
```

The output, `avg`, is an array that you can expand as required to accommodate the running averages. As a new running average is calculated, it is added to the array `avg` through concatenation, thereby expanding the array.

Because the maximum number of running averages is equal to the number of elements in `NumArray`, you can supply an explicit upper bound for `avg` in the `coder.varsize` statement. In this example, the upper bound is 8 (the two initial elements plus the six elements of `NumArray`).

2 Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned an array of size 8 (static memory allocation). The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void RunningAverage (double N, double avg_data[8], int avg_size[2])
```

3. By contrast, if you remove the explicit upper bound, the generated code dynamically allocates `avg`.

   Replace the statement

   ```
   coder.varsize('avg',[1 8]);
   ```

   with:

   ```
   coder.varsize('avg');
   ```

4. Generate code for `RunningAverage` with input argument of type `double`:

   ```
   codegen -config:lib -report RunningAverage -args 2
   ```

   In the generated code, `avg` is assigned a pointer to an array, thereby allowing dynamic memory allocation. The function definition for `RunningAverage` appears as follows (using built-in C types):

   ```
   void Test(double N, emxArray_real_T *avg)
   ```

Note: Dynamic memory allocation also occurs if you precede `coder.varsize('avg')` with the following assert statement:

```
assert(N < 6);
```

The `assert` statement does not restrict the number of concatenations within the loop.

- **Constrain Array Size When Rearranging a Matrix**

  The statement `out = reshape(in,m,n,...)` takes an array, `in`, as an argument and returns array, `out`, having the same elements as `in`, but reshaped as an `m`-by-`n`-by-`...` matrix. If one of the size variables `m,n,...` is not a compile-time constant, then dynamic memory allocation of `out` takes place.

To avoid dynamic memory allocation, use an `assert` statement before the `reshape` statement to restrict the size variables `m,n,...` to `numel(in)`. This example shows how to use an `assert` statement before a `reshape` statement:

Rearrange a Matrix into Given Number of Rows

1. Define a function, `ReshapeMatrix`, which takes an input variable, `N`, and reshapes a matrix, `mat`, to have `N` rows:

```
function [out1,out2] = ReshapeMatrix(N)

mat = [1 2 3 4 5; 4 5 6 7 8]
% Since mat has 10 elements, N must be a factor of 10
% to pass as argument to reshape

out1 = reshape(mat,N,[]);
% N is not restricted

assert(N < numel(mat));
% N is restricted to number of elements in mat
out2 = reshape(mat,N,[]);
```

2. Generate code for `ReshapeArray` using the `codegen` command (the input argument does not have to be a factor of 10):

```
codegen -config:lib -report ReshapeArray -args 3
```

While `out1` is dynamically allocated, `out2` is assigned an array with size 100 (=10 X 10) in the generated code.

Tip If your system has limited memory, do not use the `assert` statement in this way. For an `n`-element matrix, the `assert` statement creates an `n`-by-`n` matrix, which might be large.

- "Dynamic Memory Allocation and Performance"

Disable Dynamic Memory Allocation During Code Generation

To disable dynamic memory allocation using the MATLAB Coder app:

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
2. Click **More Settings**.
3. On the **Memory** tab, under **Variable Sizing Support**, set **Dynamic memory allocation** to `Never`.

To disable dynamic memory allocation at the command line:

1. In the MATLAB workspace, define the configuration object:

   ```
   cfg=coder.config('lib');
   ```

2. Set the `DynamicMemoryAllocation` property of the configuration object to `Off`:

   ```
   cfg.DynamicMemoryAllocation = 'Off';
   ```

If a variable-size array in the MATLAB code does not have a maximum upper bound, disabling dynamic memory allocation leads to a code generation error. Therefore, you can identify variable-size arrays in your MATLAB code that do not have a maximum upper bound. These arrays are the arrays that are dynamically allocated in the generated code.

Set Dynamic Memory Allocation Threshold

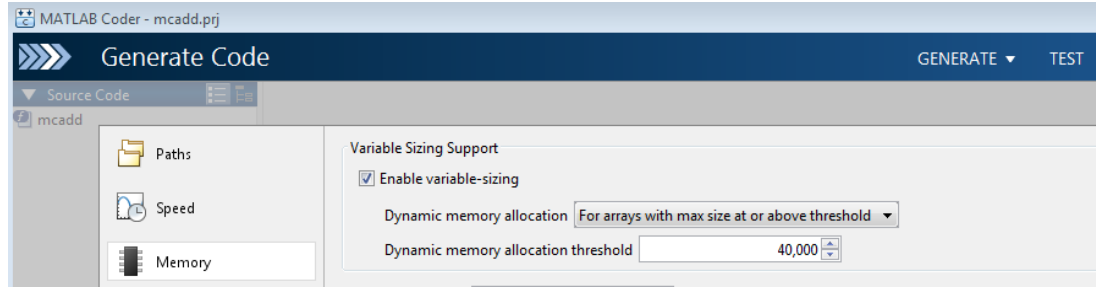
This example shows how to specify a dynamic memory allocation threshold for variable-size arrays. Dynamic memory allocation optimizes storage requirements for variable-size arrays, but causes slower execution of generated code. Instead of disabling dynamic memory allocation for all variable-size arrays, you can disable dynamic memory allocation for arrays less than a certain size.

Specify this threshold when you want to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. Static memory allocation can lead to unused storage space. However, you can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

Set Dynamic Memory Allocation Threshold Using the MATLAB Coder App

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
2. Click **More Settings**.
3. On the **Memory** tab, select the **Enable variable-sizing** check box.
4. Set **Dynamic memory allocation** to `For arrays with max size at or above threshold`.
5. Set **Dynamic memory allocation threshold** to the value that you want.



The **Dynamic memory allocation threshold** value is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accomodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Set Dynamic Memory Allocation Threshold at the Command Line

1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

   ```
   cfg = coder.config('lib');
   ```

2. Set `DynamicMemoryAllocation` to `'Threshold'`.

   ```
   cfg.DynamicMemoryAllocation='Threshold';
   ```

3. Set the property, `DynamicMemoryAllocationThreshold`, to the value that you want.

   ```
   cfg.DynamicMemoryAllocationThreshold = 40000;
   ```

   The value stored in `DynamicMemoryAllocationThreshold` is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accomodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Excluding Unused Paths from Generated Code

In certain situations, you do not need some branches of an: `if, elseif, else` statement, or a `switch, case, otherwise` statement in your generated code. For instance:

- You have a MATLAB function that performs multiple tasks determined by a control-flow variable. You might not need some of the tasks in the code generated from this function.
- You have an `if/elseif/if` statement in a MATLAB function performing different tasks based on the nature (type/value) of the input. In some cases, you know the nature of the input beforehand. If so, you do not need some branches of the `if` statement.

You can prevent code generation for the unused branches of an `if/elseif/else` statement or a `switch/case/otherwise` statement. Declare the control-flow variable as a constant. The code generation software generates code only for the branch that the control-flow variable chooses.

Related Examples

- "Prevent Code Generation for Unused Execution Paths"

Prevent Code Generation for Unused Execution Paths

In this section...
“Prevent Code Generation When Local Variable Controls Flow” on page 56-30
“Prevent Code Generation When Input Variable Controls Flow” on page 56-31

If a variable controls the flow of an: `if, elseif, else` statement, or a `switch, case, otherwise` statement, declare it as constant so that code generation takes place for one branch of the statement only.

Depending on the nature of the control-flow variable, you can declare it as constant in two ways:

- If the variable is local to the MATLAB function, assign it to a constant value in the MATLAB code. For an example, see “Prevent Code Generation When Local Variable Controls Flow” on page 56-30.
- If the variable is an input to the MATLAB function, you can declare it as constant using coder.Constant. For an example, see “Prevent Code Generation When Input Variable Controls Flow” on page 56-31.

Prevent Code Generation When Local Variable Controls Flow

1 Define a function `SquareOrCube` which takes an input variable, `in`, and squares or cubes its elements based on whether the choice variable, `ch`, is set to `s` or `c`:

```
function out = SquareOrCube(ch,in) %#codegen
 if ch=='s'
     out = in.^2;
 elseif ch=='c'
     out = in.^3;
 else
     out = 0;
 end
```

2 Generate code for `SquareOrCube` using the `codegen` command:

```
codegen -config:lib SquareOrCube -args {'s',zeros(2,2)}
```

The generated C code squares or cubes the elements of a 2-by-2 matrix based on the input for `ch`.

3 Add the following line to the definition of `SquareOrCube`:

```
ch = 's';
```

The generated C code squares the elements of a 2-by-2 matrix. The choice variable, `ch`, and the other branches of the `if/elseif/if` statement do not appear in the generated code.

Prevent Code Generation When Input Variable Controls Flow

1 Define a function `MathFunc`, which performs different mathematical operations on an input, `in`, depending on the value of the input, `flag`:

```
function out = MathFunc(flag,in) %#codegen
  %# codegen
   switch flag
     case 1
        out=sin(in);
     case 2
        out=cos(in);
     otherwise
        out=sqrt(in);
   end
```

2 Generate code for `MathFunc` using the `codegen` command:

```
codegen -config:lib MathFunc -args {1,zeros(2,2)}
```

The generated C code performs different math operations on the elements of a 2-by-2 matrix based on the input for `flag`.

3 Generate code for `MathFunc`, declaring the argument, `flag`, as a constant using coder.Constant:

```
codegen -config:lib MathFunc -args {coder.Constant(1),zeros(2,2)}
```

The generated C code finds the sine of the elements of a 2-by-2 matrix. The variable, `flag`, and the `switch/case/otherwise` statement do not appear in the generated code.

- "Excluding Unused Paths from Generated Code"

Generate Code with Parallel for-Loops (parfor)

This example shows how to generate C code for a MATLAB algorithm that contains a `parfor`-loop.

1. Write a MATLAB function that contains a `parfor`-loop. For example:

   ```
   function a = test_parfor %#codegen
   a=ones(10,256);
   r=rand(10,256);
   parfor i=1:10
     a(i,:)=real(fft(r(i,:)));
   end
   ```

2. Generate C code for `test_parfor`. At the MATLAB command line, enter:

   ```
   codegen -config:lib test_parfor
   ```

   Because you did not specify the maximum number of threads to use, the generated C code executes the loop iterations in parallel on the available number of cores.

3. To specify a maximum number of threads, rewrite the function `test_parfor` as follows:

   ```
   function a = test_parfor(u) %#codegen
   a=ones(10,256);
   r=rand(10,256);
   parfor (i=1:10,u)
     a(i,:)=real(fft(r(i,:)));
   end
   ```

4. Generate C code for `test_parfor`. Use `-args 0` to specify that the input, `u`, is a scalar double. At the MATLAB command line, enter:

   ```
   codegen -config:lib test_parfor -args 0
   ```

   In the generated code, the iterations of the `parfor`-loop run on at most the number of cores specified by the input, `u`. If less than `u` cores are available, the iterations run on the cores available at the time of the call.

Minimize Redundant Operations in Loops

This example shows how to minimize redundant operations in loops. When a loop operation does not depend on the loop index, performing it inside a loop is redundant. This redundancy often goes unnoticed when you are performing multiple operations in a single MATLAB statement inside a loop. For example, in the following code, the inverse of the matrix `B` is being calculated 100 times inside the loop although it does not depend on the loop index:

```
for i=1:100
     C=C + inv(B)*A^i*B;
  end
```

Performing such redundant loop operations can lead to unnecessary processing. To avoid unnecessary processing, move operations outside loops as long as they do not depend on the loop index.

1. Define a function, `SeriesFunc(A,B,n)`, that calculates the sum of `n` terms in the following power series expansion:

   $$C = 1 + B^{-1}AB + B^{-1}A^2B + \ldots$$

   ```
   function C=SeriesFunc(A,B,n)

   % Initialize C with a matrix having same dimensions as A
   C=zeros(size(A));

   % Perform the series sum
   for i=1:n
      C=C+inv(B)*A^i*B;
   end
   ```

2. Generate code for `SeriesFunc` with 4-by-4 matrices passed as input arguments for `A` and `B`:

   ```
   X = coder.typeof(zeros(4));
   codegen -config:lib -launchreport SeriesFunc -args {X,X,10}
   ```

   In the generated code, the inversion of `B` is performed `n` times inside the loop. It is more economical to perform the inversion operation once outside the loop because it does not depend on the loop index.

3. Modify `SeriesFunc` as follows:

```
  function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
  C=zeros(size(A));

% Perform the inversion outside the loop
  inv_B=inv(B);

% Perform the series sum
  for i=1:n
     C=C+inv_B*A^i*B;
  end
```

This procedure performs the inversion of `B` only once, leading to faster execution of the generated code.

Unroll for-Loops

Unrolling `for`-loops eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant.

You can also force loop unrolling for individual functions by wrapping the loop header in a `coder.unroll` function. For more information, see `coder.unroll`.

Limit Copying the `for`-loop Body in Generated Code

To limit the number of times that you copy the body of a `for`-loop in generated code:

1. Write a MATLAB function `getrand(n)` that uses a `for`-loop to generate a vector of length `n` and assign random numbers to specific elements. Add a test function `test_unroll`. This function calls `getrand(n)` with `n` equal to values both less than and greater than the threshold for copying the `for`-loop in generated code.

```
function [y1, y2] = test_unroll() %#codegen
% The directive %#codegen indicates that the function
% is intended for code generation
  % Calling getrand 8 times triggers unroll
  y1 = getrand(8);
  % Calling getrand 50 times does not trigger unroll
  y2 = getrand(50);

function y = getrand(n)
  % Turn off inlining to make
  % generated code easier to read
  coder.inline('never');

  % Set flag variable dounroll to repeat loop body
  % only for fewer than 10 iterations
  dounroll = n < 10;
  % Declare size, class, and complexity
  % of variable y by assignment
  y = zeros(n, 1);
  % Loop body begins
  for i = coder.unroll(1:2:n, dounroll)
      if (i > 2) && (i < n-2)
          y(i) = rand();
      end;
```

```
  end;
  % Loop body ends
```

2 In the default output folder, `codegen/lib/test_unroll`, generate C static library code for `test_unroll`:

```
codegen -config:lib test_unroll
```

In `test_unroll.c`, the generated C code for `getrand(8)` repeats the body of the `for`-loop (unrolls the loop) because the number of iterations is less than 10:

```
static void getrand(double y[8])
{
  /*  Turn off inlining to make  */
  /*  generated code easier to read */
  /*  Set flag variable dounroll to repeat loop body */
  /*  only for fewer than 10 iterations */
  /*  Declare size, class, and complexity */
  /*  of variable y by assignment */
  memset(&y[0], 0, sizeof(double) << 3);

  /*  Loop body begins */
  y[2] = b_rand();
  y[4] = b_rand();

  /*  Loop body ends */
}
```

The generated C code for `getrand(50)` does not unroll the `for`-loop because the number of iterations is greater than 10:

```
static void b_getrand(double y[50])
{
  int i;
  int b_i;

  /*  Turn off inlining to make  */
  /*  generated code easier to read */
  /*  Set flag variable dounroll to repeat loop body */
  /*  only for fewer than 10 iterations */
  /*  Declare size, class, and complexity */
  /*  of variable y by assignment */
  memset(&y[0], 0, 50U * sizeof(double));

  /*  Loop body begins */
```

```
for (i = 0; i < 25; i++) {
  b_i = (i << 1) + 1;
  if ((b_i > 2) && (b_i < 48)) {
    y[b_i - 1] = b_rand();
  }
}
```

Support for Integer Overflow and Non-Finites

The code generation software generates supporting code for the following situations:

- The result of an integer operation falls outside the range that a data type can represent. This situation is known as integer overflow.
- An operation generates non-finite values (`inf` and `NaN`). The supporting code is contained in the files `rt_nonfinite.c`, `rtGetInf.c`, and `rtGetNaN.c` (with corresponding header files).

If you know that these situations do not occur, you can suppress generation of the supporting code. You therefore reduce the size of the generated code and increase its speed. However, if one of these situations occurs, it is possible that the generated code will not match the behavior of the original MATLAB code.

Disable Support for Integer Overflow

You can use the MATLAB Coder app or the command-line interface to disable support for integer overflow. When you disable this support, the overflow behavior of your generated code depends on your target C compiler. Most C compilers wrap on overflow.

- Using the app:

  1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
  2. Click **More Settings**.
  3. To disable support for integer overflow, on the **Speed** tab, clear `Saturate on integer overflow`.

- At the command line:

  1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

     ```
     cfg = coder.config('lib');
     ```

  2. To disable support for integer overflow, set the `SaturateOnIntegerOverflow` property to `false`.

     ```
     cfg.SaturateOnIntegerOverflow = false;
     ```

Disable Support for Non-Finite Numbers

You can use the MATLAB Coder app or the command-line interface to disable support for non-finite numbers(`inf` and `NaN`).

- Using the app:

  1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
  2. Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
  3. Click **More Settings**.
  4. On the **Speed** tab, clear the **Support non-finite numbers** check box.

- At the command line:

  1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

     ```
     cfg = coder.config('lib');
     ```

  2. To disable support for integer overflow, set the `SupportNonFinite` property to `false`.

     ```
     cfg.SupportNonFinite = false;
     ```

Integrate External/Custom Code

This example shows how to integrate external or custom code to enhance performance of generated code. Although MATLAB Coder generates optimized code for most applications, you might have custom code optimized for your specific requirements. For example:

- You have custom libraries optimized for your target environment.
- You have custom libraries for functions not supported by MATLAB Coder.
- You have custom libraries that meet standards set by your company.

In such cases, you can integrate your custom code with the code generated by MATLAB Coder.

This example illustrates how to integrate the function `cublasSgemm` from the NVIDIA® CUDA® Basic Linear Algebra Subroutines (CUBLAS) library in generated code. This function performs matrix multiplication on a Graphics Processing Unit (GPU).

1. Define a class `ExternalLib_API` that derives from the class `coder.ExternalDependency`. `ExternalLib_API` defines an interface to the `CUBLAS` library through the following methods:

   - `getDescriptiveName`: Returns a descriptive name for `ExternalLib_API` to be used for error messages.
   - `isSupportedContext`: Determines if the build context supports the `CUBLAS` library.
   - `updateBuildInfo`: Adds header file paths and link files to the build information.
   - `GPU_MatrixMultiply`: Defines the interface to the `CUBLAS` library function `cublasSgemm`.

   ExternalLib_API.m

   ```
   classdef ExternalLib_API < coder.ExternalDependency
       %#codegen

       methods (Static)

           function bName = getDescriptiveName(~)
               bName = 'ExternalLib_API';
   ```

```
end

function tf = isSupportedContext(ctx)
    if  ctx.isMatlabHostTarget()
        tf = true;
    else
        error('CUBLAS library not available for this target');
    end
end

function updateBuildInfo(buildInfo, ctx)
    [~, linkLibExt, ~, ~] = ctx.getStdLibInfo();

    % Include header file path
    % Include header files later using coder.cinclude
    hdrFilePath = 'C:\My_Includes';
    buildInfo.addIncludePaths(hdrFilePath);

    % Include link files
    linkFiles = strcat('libcublas', linkLibExt);
    linkPath = 'C:\My_Libs';
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    linkFiles = strcat('libcudart', linkLibExt);
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

end

%API for library function 'cuda_MatrixMultiply'
function C = GPU_MatrixMultiply(A, B)
    assert(isa(A,'single'), 'A must be single.');
    assert(isa(B,'single'), 'B must be single.');

    if(coder.target('MATLAB'))
        C=A*B;
    else

        % Include header files
```

```
%     for external functions and typedefs
% Header path included earlier using updateBuildInfo
coder.cinclude('"cuda_runtime.h"');
coder.cinclude('"cublas_v2.h"');

% Compute dimensions of input matrices
m = int32(size(A, 1));
k = int32(size(A, 2));
n = int32(size(B, 2));

% Declare pointers to matrices on destination GPU
d_A = coder.opaque('float*');
d_B = coder.opaque('float*');
d_C = coder.opaque('float*');

% Compute memory to be allocated for matrices
% Single = 4 bytes
size_A = m*k*4;
size_B = k*n*4;
size_C = m*n*4;

% Define error variables
error = coder.opaque('cudaError_t');
cudaSuccessV = coder.opaque('cudaError_t', ...
    'cudaSuccess');

% Assign memory on destination GPU
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_A), size_A);
assert(error == cudaSuccessV, ...
    'cudaMalloc(A) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_B), size_B);
assert(error == cudaSuccessV, ...
    'cudaMalloc(B) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_C), size_C);
assert(error == cudaSuccessV, ...
    'cudaMalloc(C) failed');

% Define direction of copying
hostToDevice = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyHostToDevice');
```

```
% Copy matrices to destination GPU
error = coder.ceval('cudaMemcpy',  ...
    d_A, coder.rref(A), size_A, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(A) failed');

error = coder.ceval('cudaMemcpy',  ...
    d_B, coder.rref(B), size_B, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(B) failed');

% Define type and size for result
C = zeros(m, n, 'single');

error = coder.ceval('cudaMemcpy', ...
    d_C, coder.rref(C), size_C, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

% Define handle variables for external library
handle = coder.opaque('cublasHandle_t');
blasSuccess = coder.opaque('cublasStatus_t', ...
    'CUBLAS_STATUS_SUCCESS');

% Initialize external library
ret = coder.opaque('cublasStatus_t');
ret = coder.ceval('cublasCreate', coder.wref(handle));
assert(ret == blasSuccess, 'cublasCreate failed');

TRANSA = coder.opaque('cublasOperation_t', ...
    'CUBLAS_OP_N');
alpha = single(1);
beta = single(0);

% Multiply matrices on GPU
ret = coder.ceval('cublasSgemm', handle, ...
    TRANSA,TRANSA,m,n,k, ...
    coder.rref(alpha),d_A,m, ...
    d_B,k, ...
    coder.rref(beta),d_C,k);

assert(ret == blasSuccess, 'cublasSgemm failed');

% Copy result back to local host
deviceToHost = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyDeviceToHost');
```

```
                    error = coder.ceval('cudaMemcpy', coder.wref(C), ...
                        d_C, size_C, deviceToHost);
                    assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

                end
            end
        end
    end
```

2 To perform the matrix multiplication using the interface defined in method `GPU_MatrixMultiply` and the build information in `ExternalLib_API`, include the following line in your MATLAB code:

```
C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

For instance, you can define a MATLAB function `Matrix_Multiply` that solely performs this matrix multiplication.

```
function C = Matrix_Multiply(A, B) %#codegen
 C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

3 Define a `MEX` configuration object using `coder.config`. For using the `CUBLAS` libraries, set the target language for code generation to `C++`.

```
cfg=coder.config('mex');
cfg.TargetLang='C++';
```

4 Generate code for `Matrix_Multiply` using `cfg` as the configuration object and two `2 X 2` matrices of type `single` as arguments. Since `cublasSgemm` supports matrix multiplication for data type `float`, the corresponding MATLAB matrices must have type `single`.

```
codegen -config cfg Matrix_Multiply ...
            -args {ones(2,'single'),ones(2,'single')}
```

5 Test the generated `MEX` function `Matrix_Multiply_mex` using two `2 X 2` identity matrices of type `single`.

```
Matrix_Multiply_mex(eye(2,'single'),eye(2,'single'))
```

The output is also a `2 X 2` identity matrix.

Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation”.

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

LAPACK Calls for Linear Algebra in a MATLAB Function Block

To improve the simulation speed of `MATLAB Function` block algorithms that call certain linear algebra functions, Simulink can call LAPACK functions. LAPACK is a software library for numerical linear algebra. If the input arrays for the linear algebra functions meet certain criteria, the simulation calls LAPACK functions in the LAPACK library that is included with MATLAB. MATLAB uses LAPACK in some linear algebra functions such as `eig` and `svd`.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce LAPACK function calls. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet the criteria, the code generator produces LAPACK calls. The build process links to the LAPACK library that you specify. See "Speed Up Linear Algebra in Code Generated from a MATLAB Function Block" in the Simulink Coder documentation.

About Data Types in Simulink

In this section...
“About Data Types” on page 57-2
“Data Typing Guidelines” on page 57-3
“Data Type Propagation” on page 57-3

About Data Types

The term *data type* refers to the way in which a computer represents numbers in memory. A data type determines the amount of storage allocated to a number, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. The Simulink software builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (`double`) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 57-3). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

  A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.
- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, the Simulink software converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

  Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.
- Virtual blocks accept signals of any type on their inputs.

  Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.
- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.
- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only `double` signals.
- Connecting a non-`double` signal to a block disables zero-crossing detection for that block.

Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, the Simulink software performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

Note You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see `Data Type Conversion`.

Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types except `int64` and `uint64`. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

Name	Description
`double`	Double-precision floating point
`single`	Single-precision floating point
`int8`	Signed 8-bit integer
`uint8`	Unsigned 8-bit integer
`int16`	Signed 16-bit integer
`uint16`	Unsigned 16-bit integer
`int32`	Signed 32-bit integer
`uint32`	Unsigned 32-bit integer

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values **1** and **0** represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (**1**).

Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Bus Signals” on page 57-53.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 57-38. For more

information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

- "Data Types for Bus Signals" on page 57-53

Control Signal Data Types

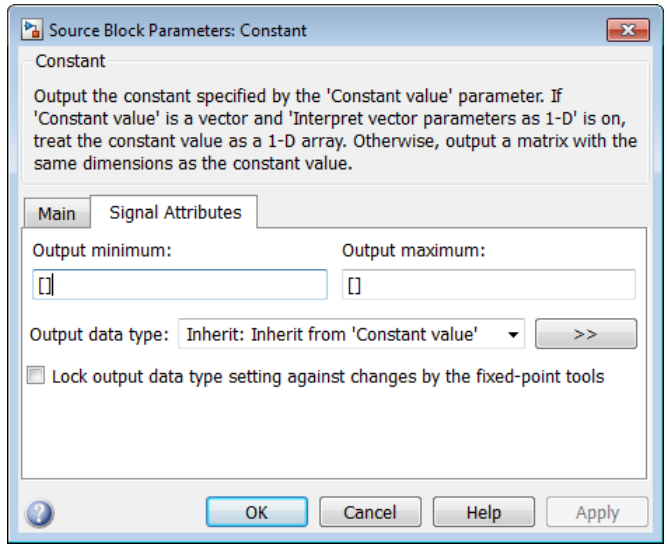
To view the signal data types in your model, in the Simulink Editor, select **Display** > **Signals & Ports** > **Port Data Types**. The port data type display is not automatically updated when you change the data type of a diagram element. To refresh the display, press **Ctrl+D**.

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level `Inport` block or a `From Workspace` block.
- Create a `Constant` block in your model and set its parameter to the desired type.
- Use a `Data Type Conversion` block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.



See the following topics for more information:

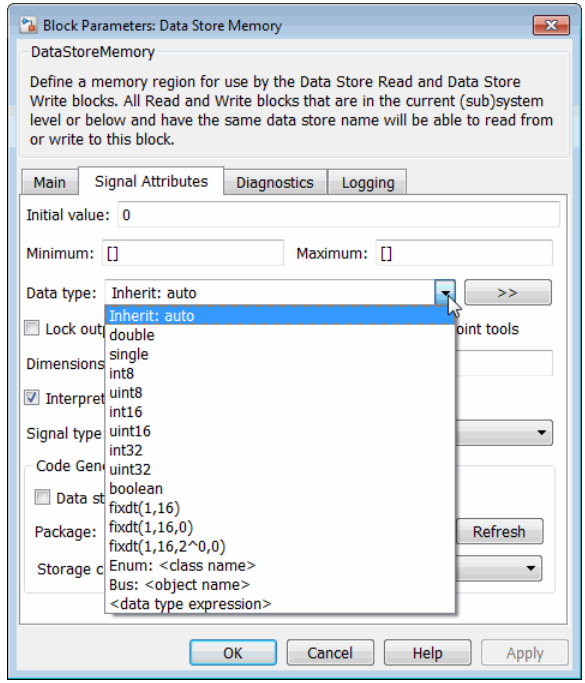
For Information About...	See...
Valid data type values that you can specify	"Entering Valid Data Type Values" on page 57-9
An assistant that helps you specify valid data type values	"Specify Data Types Using Data Type Assistant" on page 57-40
Specifying valid data type values for multiple blocks simultaneously	"Using the Model Explorer for Batch Editing" on page 57-12

Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see "Data Type Inheritance Rules" on page 57-10)
- The name of a built-in data type (see "Built-In Data Types" on page 57-11)
- An expression that evaluates to a data type (see "Data Type Expressions" on page 57-11)

Valid data type values vary among blocks. You can use the pull-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** pull-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.



For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type pull-down menu on the block dialog box. The following table lists typical rules that you can select.

Inheritance Rule	Description
`Inherit: Inherit via back propagation`	Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 57-3). In this case, the block uses the data type of a downstream block or signal object.

Inheritance Rule	Description
`Inherit: Same as input`	The block uses the data type of its sole input signal for its output signal.
`Inherit: Same as first input`	The block uses the data type of its first input signal for its output signal.
`Inherit: Same as second input`	The block uses the data type of its second input signal for its output signal.
`Inherit: Inherit via internal rule`	The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time.

Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type pull-down menu on the block dialog box. See "Data Types Supported by Simulink" on page 57-5 for a list of all built-in data types that are supported.

Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of the following expressions:

- **`fixdt` Command**

  Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type. See the documentation for the `fixdt` function for more information.

- **Data Type Object Name**

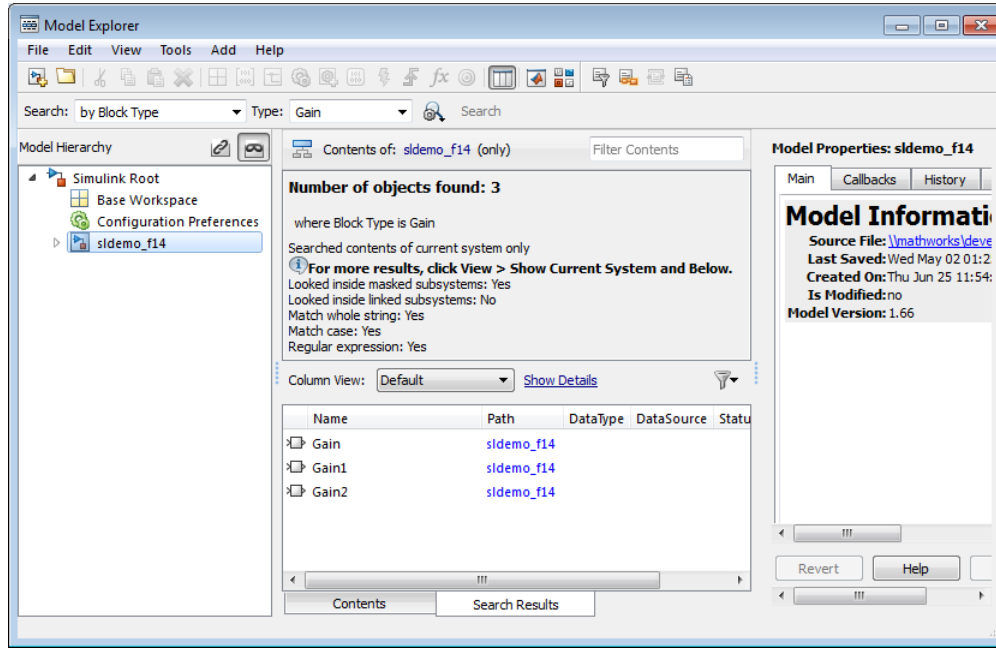
Specify the value of a data type parameter as the name of a data object that represents a data type. Simulink data objects that you instantiate from classes, such as `Simulink.NumericType` and `Simulink.AliasType`, simplify the task of making model-wide changes to output data types and allow you to use custom aliases for data types. See "Data Objects" on page 57-54 for more information about Simulink data objects.

Using the Model Explorer for Batch Editing

Using the Model Explorer (see "Model Explorer Overview" on page 12-2), you can assign the same output data type to multiple blocks simultaneously. For example, the `slexAircraftExample` model that comes with the Simulink product contains numerous Gain blocks. Suppose you want to specify the **Output data type** parameter of all the Gain blocks in the model as `single`. You can achieve this task as follows:

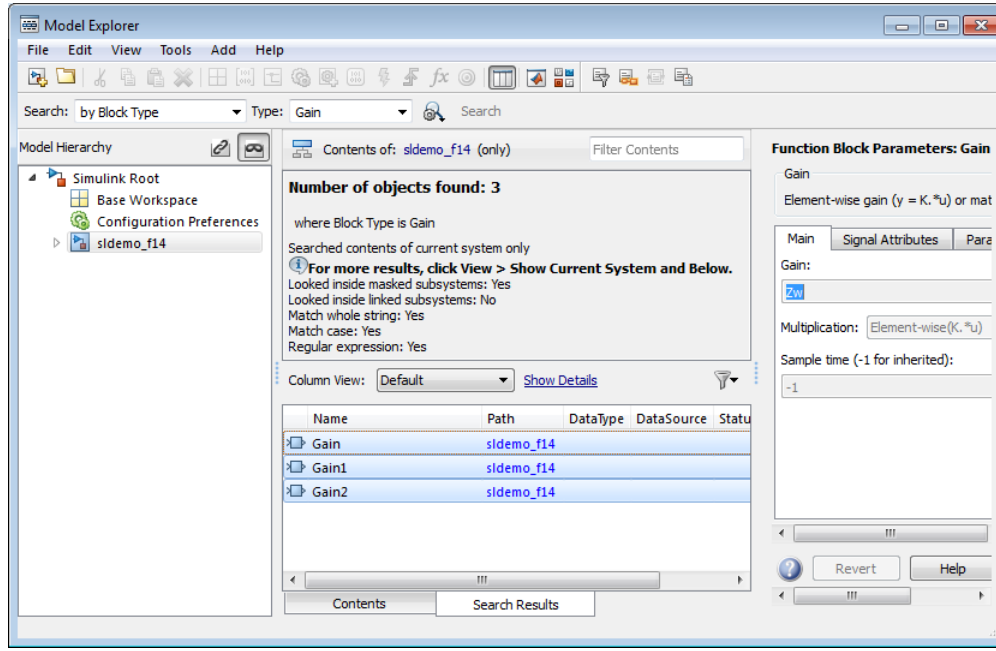
1 Use the Model Explorer search bar (see "Search Using Model Explorer" on page 12-65) to identify all blocks in the `slexAircraftExample` model of type `Gain`.

   The Model Explorer **Contents** pane lists all Gain blocks in the model.



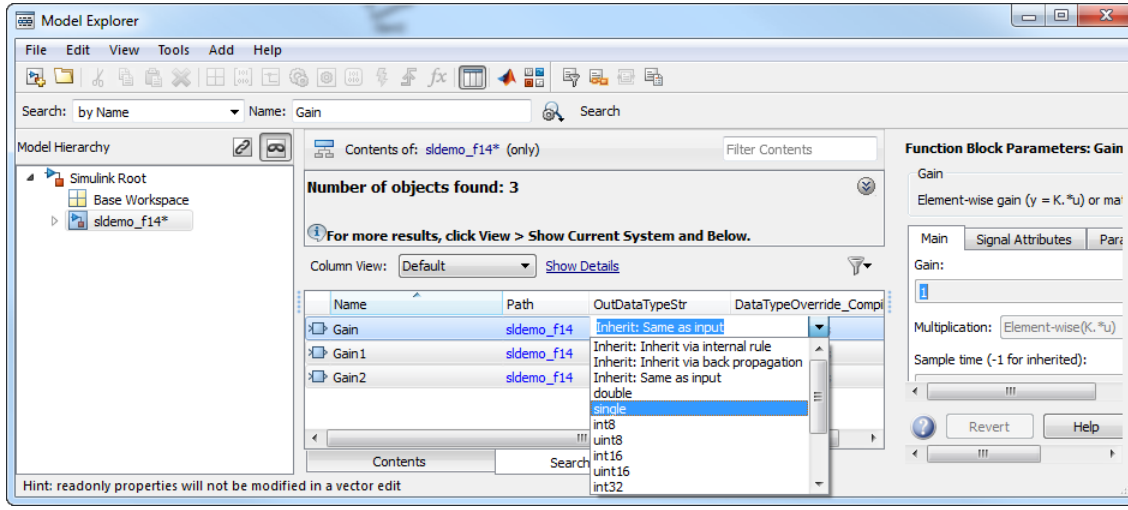
2 In the Model Explorer **Contents** pane, select all the Gain blocks whose **Output data type** parameter you want to specify.

Model Explorer highlights the rows corresponding to your selections.



3 In the Model Explorer **Contents** pane, click the data type associated with one of the selected Gain blocks.

Model Explorer displays a pull-down menu with valid data type options.



4 In the pull-down menu, enter or select the desired data type, for example, `single`.

Model Explorer specifies the data type of all selected items as `single`.

Validate a Floating-Point Embedded Model

You can use data type override mode to switch the data types in your model. This capability allows you to maintain one model but simulate and generate code for multiple data types, and also validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without affecting any other data types in your model.

Apply a Data Type Override to Floating-Point Data Types

To apply a data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set a data type override using one of the following methods. In these examples, both methods change all floating-point data types to single.

From the Command Line

For example:

```
set_param(gcs, 'DataTypeOverride', 'Single');
set_param(gcs, 'DataTypeOverrideAppliesTo','Floating-point');
```

Using the Fixed-Point Tool

For example:

1. In the Simulink Editor, select **Analysis** > **Fixed-Point Tool**.

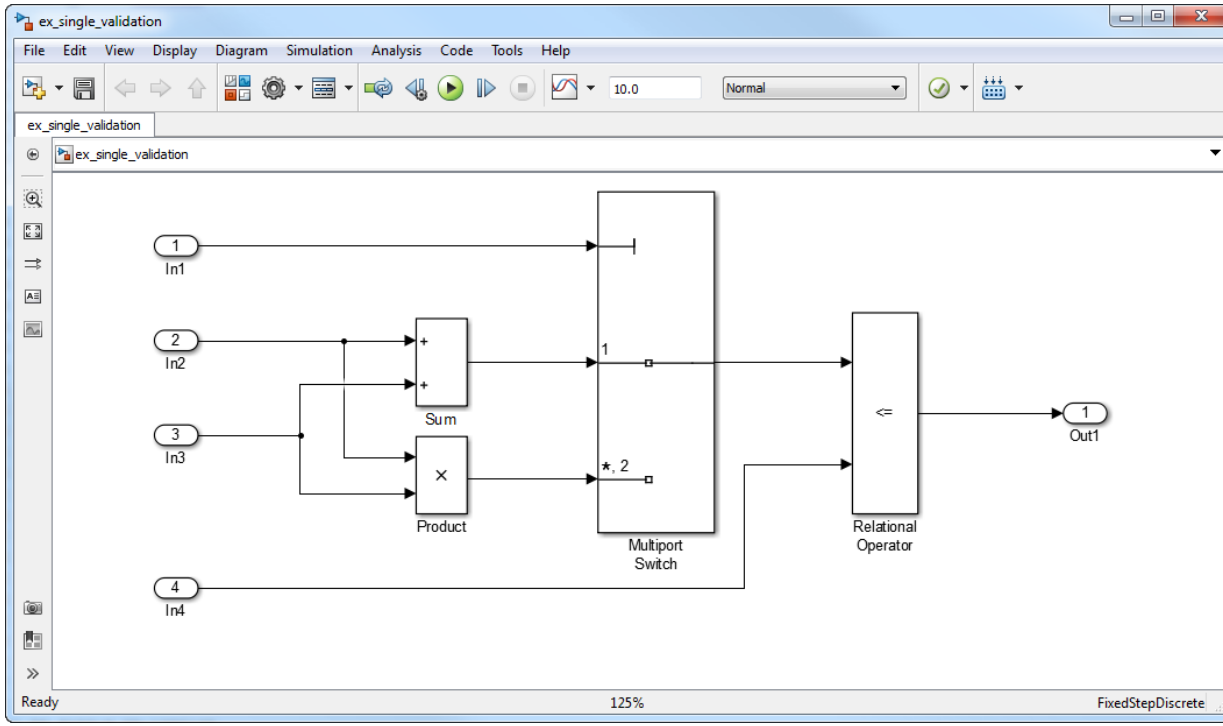
   The Fixed-Point Tool opens.
2. Select **View** > **Show Settings for Selected System**.
3. In the Fixed-Point Tool right pane, under **Settings for selected system**:
   a. Set **Data type override** to `Single`.
   b. Set **Data type override applies** to `Floating-point`.

For more information on data type override settings, see `fxptdlg`.

Validate a Single-Precision Model

This example uses the `ex_single_validation` model to show how you can use data type overrides. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

About the Model



- The inputs `In2` and `In3` are double-precision inputs to the `Sum` and `Product` blocks.
- The outputs of the `Sum` and `Product` blocks are data inputs to the `Multiport Switch` block.
- The input `In1` is the control input to the `Multiport Switch` block. The value of this control input determines which of its other inputs, the sum of `In2` and `In3` or the product of `In2` and `In3`, passes to the output port. Because `In1` is a control input, its data type is `int8`.

- The `Relational Operator` block compares the output of the `Multiport Switch` block to `In4`, and outputs a Boolean signal.

Run the Example

Open the Model

1. Open the `ex_single_validation` model. At the MATLAB command line, enter:

   ```
   addpath(fullfile(docroot,'toolbox','simulink','examples'))
   ex_single_validation
   ```

Run Model Advisor Check

1. From the model menu, select **Analysis** > **Model Advisor** > **Model Advisor**.
2. In the System Selector dialog box, click **OK**.

   The Model Advisor opens.
3. In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precison design** check.
4. In the right pane, click **Run This Check**.

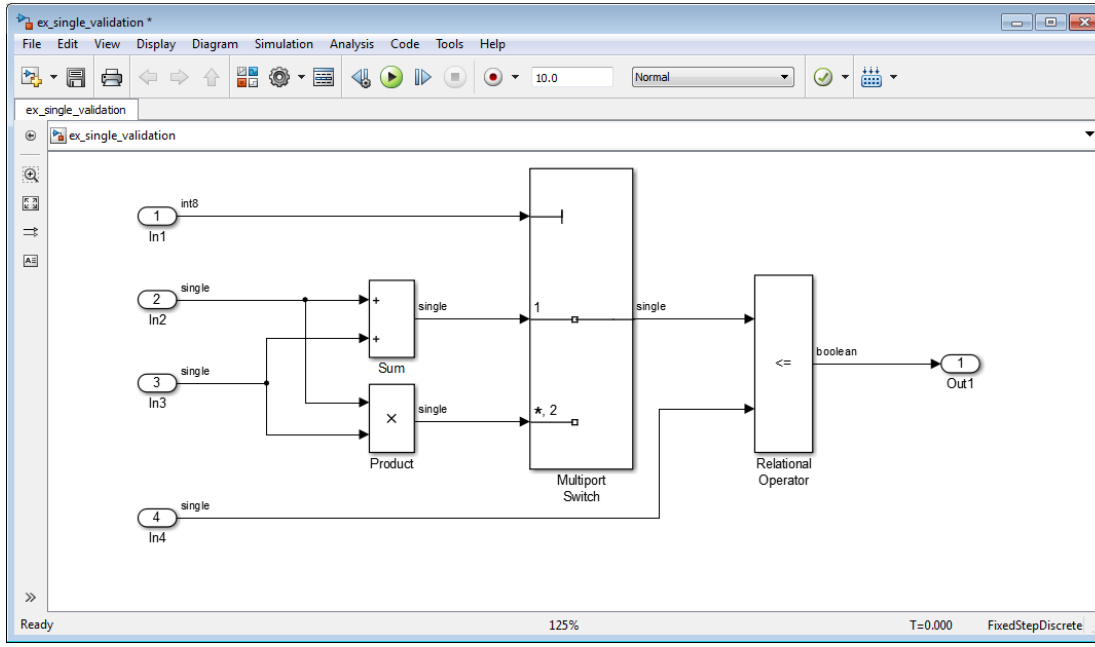
   The check generates a warning that multiple blocks use double-precision floating-point operations.

Override Floating-Point Data Types With Singles

1. In the Simulink Editor, select **Analysis** > **Fixed-Point Tool**.

   The Fixed-Point Tool opens.
2. In the Fixed-Point Tool right pane, under **Settings for selected system**:
   a. Set **Data type override** to `Single`.
   b. Set **Data type override applies to** `Floating-point`.
   c. Click **Apply**.
3. In the model menu, select **Simulation** > **Update Diagram**.

   The data type override replaces all the floating-point (`double`) data types in the model with `single` data types, but does not affect the integer or Boolean data types.



Re-run the Model Advisor Check

In the Model Advisor, run the **Identify questionable operations for strict single-precison design** check again.

The check passes indicating that this algorithm is suitable for single-precision embedded use.

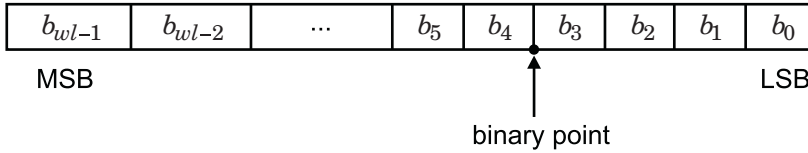
Fixed-Point Numbers

In this section...
“Binary Point Interpretation” on page 57-22
“Signed Fixed-Point Numbers” on page 57-23

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of binary digits (1's and 0's). The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type. There are several distinct differences between fixed-point data types and the built-in integer types in MATLAB®. The most notable difference, is that the built-in integer data types can only represent whole numbers, while the fixed-point data types also contain information on the position of the binary point, or the scaling of the number.

Binary numbers are represented as either fixed-point or floating-point data types. A fixed-point data type is characterized by the word size in bits, the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted. With the Fixed-Point Designer software, fixed-point data types can be integers, fractionals, or generalized fixed-point numbers. The main difference between these data types is their default binary point. For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:



where

- b_i is the i^{th} binary digit.
- wl is the word length in bits.
- b_{wl-1} is the location of the most significant, or highest, bit (MSB).
- b_0 is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

Binary Point Interpretation

The binary point is the means by which fixed-point numbers are scaled. It is usually the software that determines the binary point. When performing basic math functions such as addition or subtraction, the hardware uses the same logic circuits regardless of the value of the scale factor. In essence, the logic circuits have no knowledge of a scale factor. They are performing signed or unsigned fixed-point binary algebra as if the binary point is to the right of b_0.

Fixed-Point Designer supports the general binary point scaling $V=Q*2\text{^}E$. `V` is the real-world value, `Q` is the stored integer value, and `E` is equal to `-FractionLength`. In other words, `RealWorldValue = StoredInteger * 2 ^ -FractionLength`.

`FractionLength` defines the scaling of the stored integer value. The word length limits the values that the stored integer can take, but it does not limit the values `FractionLength` can take. The software does not restrict the value of exponent `E` based on the word length of the stored integer `Q`. Because `E` is equal to `-FractionLength`, restricting the binary point to being contiguous with the fraction is unnecessary; the fraction length can be negative or greater than the word length.

For example, a word consisting of three unsigned bits is usually represented in scientific notation in one of the following ways.

$$bbb. = bbb. \times 2^{0}$$
$$bbb = bbb. \times 2^{-1}$$
$$b.bb = bbb. \times 2^{-2}$$
$$.bbb = bbb. \times 2^{-3}$$

If the exponent were greater than 0 or less than -3, then the representation would involve lots of zeros.

$$bbb00000. = bbb. \times 2^{5}$$
$$bbb00. = bbb. \times 2^{2}$$
$$.00bbb = bbb. \times 2^{-5}$$
$$.00000bbb = bbb. \times 2^{-8}$$

These extra zeros never change to ones, however, so they don't show up in the hardware. Furthermore, unlike floating-point exponents, a fixed-point exponent never shows up in the hardware, so fixed-point exponents are not limited by a finite number of bits.

Consider a signed value with a word length of 8, a fraction length of 10, and a stored integer value of 5 (binary value `00000101`). The real-word value is calculated using the formula
`RealWorldValue = StoredInteger * 2 ^ -FractionLength`. In this case, `RealWorldValue = 5 * 2 ^ -10 = 0.0048828125`. Because the fraction length is 2 bits longer than the word length, the binary value of the stored integer is `x.xx00000101`, where `x` is a placeholder for implicit zeros. `0.0000000101` (binary) is equivalent to `0.0048828125` (decimal). For an example using a `fi` object, see "Create a fi Object With Fraction Length Greater Than Word Length".

Signed Fixed-Point Numbers

Computer hardware typically represents the negation of a binary fixed-point number in three different ways: sign/magnitude, one's complement, and two's complement. Two's complement is the preferred representation of signed fixed-point numbers and is the only representation used by Fixed-Point Designer software.

Negation using two's complement consists of a bit inversion (translation into one's complement) followed by the addition of a one. For example, the two's complement of 000101 is 111011.

Whether a fixed-point value is signed or unsigned is usually not encoded explicitly within the binary word; that is, there is no sign bit. Instead, the sign information is implicitly defined within the computer architecture.

More About

- "Scaling, Precision, and Range" on page 57-26

Benefits of Using Fixed-Point Hardware

Digital hardware is becoming the primary means by which control systems and signal processing filters are implemented. Digital hardware can be classified as either off-the-shelf hardware (for example, microcontrollers, microprocessors, general-purpose processors, and digital signal processors) or custom hardware. Within these two types of hardware, there are many architecture designs. These designs range from systems with a single instruction, single data stream processing unit to systems with multiple instruction, multiple data stream processing units.

Within digital hardware, numbers are represented as either fixed-point or floating-point data types. For both of these data types, word sizes are fixed at a set number of bits. However, the dynamic range of fixed-point values is much less than floating-point values with equivalent word sizes. Therefore, in order to avoid overflow or unreasonable quantization errors, fixed-point values must be scaled. Since floating-point processors can greatly simplify the real-time implementation of a control law or digital filter, and floating-point numbers can effectively approximate real-world numbers, then why use a microcontroller or processor with fixed-point hardware support?

- Size and Power Consumption — The logic circuits of fixed-point hardware are much less complicated than those of floating-point hardware. This means that the fixed-point chip size is smaller with less power consumption when compared with floating-point hardware. For example, consider a portable telephone where one of the product design goals is to make it as portable (small and light) as possible. If one of today's high-end floating-point, general-purpose processors is used, a large heat sink and battery would also be needed, resulting in a costly, large, and heavy portable phone.
- Memory Usage and Speed — In general fixed-point calculations require less memory and less processor time to perform.
- Cost — Fixed-point hardware is more cost effective where price/cost is an important consideration. When digital hardware is used in a product, especially mass-produced products, fixed-point hardware costs much less than floating-point hardware and can result in significant savings.

After making the decision to use fixed-point hardware, the next step is to choose a method for implementing the dynamic system (for example, control system or digital filter). Floating-point software emulation libraries are generally ruled out because of timing or memory size constraints. Therefore, you are left with fixed-point math where binary integer values are scaled.

More About

- “Fixed-Point Numbers” on page 57-21

Scaling, Precision, and Range

In this section...
“Scaling” on page 57-26
“Precision” on page 57-27
“Range” on page 57-27

The dynamic range of fixed-point values is less than floating-point values with equivalent word sizes. To avoid overflow and minimize quantization errors, fixed-point numbers must be scaled.

Scaling

With the Fixed-Point Designer™ software, you can select a fixed-point data type whose scaling is defined by its binary point, or you can select an arbitrary linear scaling that suits your needs.

Slope and Bias Scaling

You can represent a fixed-point number by a general slope and bias encoding scheme. The real world value of a slope bias scaled number can be represented by:

$$\text{real-world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

$$\text{slope} = \text{slope adjustment factor} \times 2^{\text{fixed exponent}}$$

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in slope bias representation that has a bias equal to zero and a slope adjustment factor equal to one. This is referred to as binary point-only scaling or power-of-two scaling.

Binary-Point-Only Scaling

Binary-point-only or power-of-two scaling involves moving the binary point within the fixed-point word. The advantage of this scaling mode is to minimize the number of processor arithmetic operations. The real world value of a binary-point only scaled number can be represented by:

$$\text{real world value} = 2^{-\text{fraction length}} \times \text{integer}$$

Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

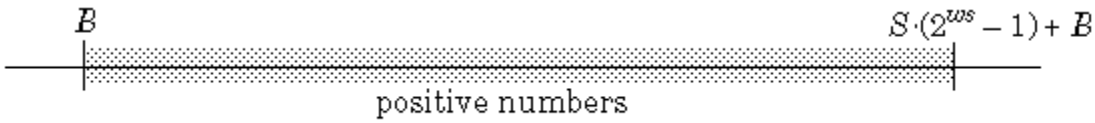
For example, a fixed-point representation with four bits to the right of the binary point has a precision of 2^{-4} or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within $(2^{-4})/2$ or 0.03125, which is half the precision.

Rounding Methods

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and scaling, a rounding method is used to cast the value to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding method itself. For more information on the rounding methods available with the Fixed-Point Designer software, see "Rounding Methods"

Range

Range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for an unsigned two's complement fixed-point number of word length *ws*, scaling *S*, and bias *B* is illustrated below:



The following figure illustrates the range of representable numbers for a two's complement signed fixed-point number:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is 2^{wl}.

For example, in two's complement, negative numbers must be represented as well as zero, so the maximum value is 2^{wl-1}-1. Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for —2^{wl-1}, but not for 2^{wl-1}.

Fixed-Point Data in MATLAB and Simulink

In this section...
“Fixed-Point Data in Simulink” on page 57-29
“Fixed-Point Data in MATLAB” on page 57-31
“Scaled Doubles” on page 57-32

Fixed-Point Data in Simulink

You can use the `fixdt` function in Simulink to specify a fixed-point data type. The `fixdt` function creates a `Simulink.NumericType` object.

Fixed-Point Data Type and Scaling Notation

Simulink data type names must be valid MATLAB identifiers with less than 128 characters. The data type name provides information about container type, number encoding, and scaling.

The following table provides a key for various symbols that appear in Simulink products to indicate the data type and scaling of a fixed-point value.

Symbol	Description	Example
Container Type		
`ufix`	Unsigned fixed-point data type	`ufix8` is an 8-bit unsigned fixed-point data type
`sfix`	Signed fixed-point data type	`sfix128` is a 128-bit signed fixed-point data type
`fltu`	Scaled double override of an unsigned fixed-point data type (`ufix`)	`fltu32` is a scaled doubles override of `ufix32`
`flts`	Scaled double override of a signed fixed-point data type (`sfix`)	`flts64` is a scaled doubles override of `sfix64`
Number Encoding		
`e`	10^	`125e8` equals `125*(10^(8))`
`n`	Negative	`n31` equals `-31`

Symbol	Description	Example

`p`	Decimal point	`1p5` equals `1.5`
		
		`p2` equals `0.2`

Scaling Encoding		
`S`	Slope	`ufix16_S5_B7` is a 16-bit unsigned fixed-point data type with `Slope` of `5` and `Bias` of `7`
`B`	Bias	`ufix16_S5_B7` is a 16-bit unsigned fixed-point data type with `Slope` of `5` and `Bias` of `7`
`E`	Fixed exponent (2^) A negative fixed exponent describes the fraction length	`sfix32_En31` is a 32-bit signed fixed-point data type with a fraction length of `31`
`F`	Slope adjustment factor	`ufix16_F1p5_En50` is a 16-bit unsigned fixed-point data type with a `SlopeAdjustmentFactor` of `1.5` and a `FixedExponent` of `-50`
C,c,D, or d	Compressed encoding for Bias **Note:** If you pass this string to the `slDataTypeAndScale` function, it returns a valid `fixdt` data type.	No example available. For backwards compatibility only. To identify and replace calls to `slDataTypeAndScale`, use the “Check for calls to slDataTypeAndScale” Model Advisor check.

Symbol	Description	Example
T or t	Compressed encoding for Slope **Note:** If you pass this string to the `slDataTypeAndScale`, it returns a valid `fixdt` data type.	No example available. For backwards compatibility only. To identify and replace calls to `slDataTypeAndScale`, use the "Check for calls to slDataTypeAndScale" Model Advisor check.

Fixed-Point Data in MATLAB

To assign a fixed-point data type to a number or variable in MATLAB, use the `fi` constructor. The resulting fixed-point value is called a `fi` object. For example, the following creates `fi` objects *a* and *b* with attributes shown in the display, all of which we can specify when the variables are constructed. Note that when the `FractionLength` property is not specified, it is set automatically to "best precision" for the given word length, keeping the most-significant bits of the value. When the `WordLength` property is not specified it defaults to 16 bits.

```
a = fi(pi)

a =

              3.1416015625

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 13

b = fi(0.1)

b =

        0.0999984741210938

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 18
```

Read Fixed-Point Data from the Workspace

Use the `From Workspace` block to read fixed-point data from the MATLAB workspace into a Simulink model. To do this, the data must be in structure format with a `fi` object in the `values` field. In array format, the `From Workspace` block only accepts real, double-precision data.

Write Fixed-Point Data to the Workspace

You can write fixed-point output from a model to the MATLAB workspace via the `To Workspace` block in either array or structure format. Fixed-point data written by a `To Workspace` block to the workspace in structure format can be read back into a Simulink model in structure format by a `From Workspace` block.

Scaled Doubles

Scaled doubles are a hybrid between floating-point and fixed-point numbers. The Fixed-Point Designer software stores them as doubles with the scaling, sign, and word length information retained. For example, the storage container for a fixed-point data type `sfix16_En14` is `int16`. The storage container of the equivalent scaled doubles data type, `flts16_En14` is floating-point `double`. The Fixed-Point Designer software applies the scaling information to the stored floating-point double to obtain the real-world value. Storing the value in a double almost always eliminates overflow and precision issues.

Share Fixed-Point Models

You can edit a model containing fixed-point blocks without the Fixed-Point Designer software. However, you must have a Fixed-Point Designer software license to

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model

If you do not have the Fixed-Point Designer software, you can work with a model containing Simulink blocks with fixed-point settings as follows:

1. In the Simulink Editor, select **Analysis** > **Fixed-Point Tool**.

   The Fixed-Point Tool opens.
2. Under **System under design**, click **Continue**.
3. In the Model Hierarchy pane, right-click the system.
   - Set `Fixed-point instrumentation mode` to `Force off`.
   - Set `Data type override` to `Double` or `Single`.
   - Set `Data type override applies to` `All numeric types`.
4. If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

   For example, at the MATLAB command line, enter:

   ```
   p = fipref('DataTypeOverride', 'TrueDoubles', ...
    'DataTypeOverrideAppliesTo', 'AllNumericTypes');
   ```

Note: If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

More About

- "Control Fixed-Point Instrumentation and Data Type Override" on page 57-35

Control Fixed-Point Instrumentation and Data Type Override

In this section...
“Control Instrumentation Settings” on page 57-35
“Control Data Type Override” on page 57-36

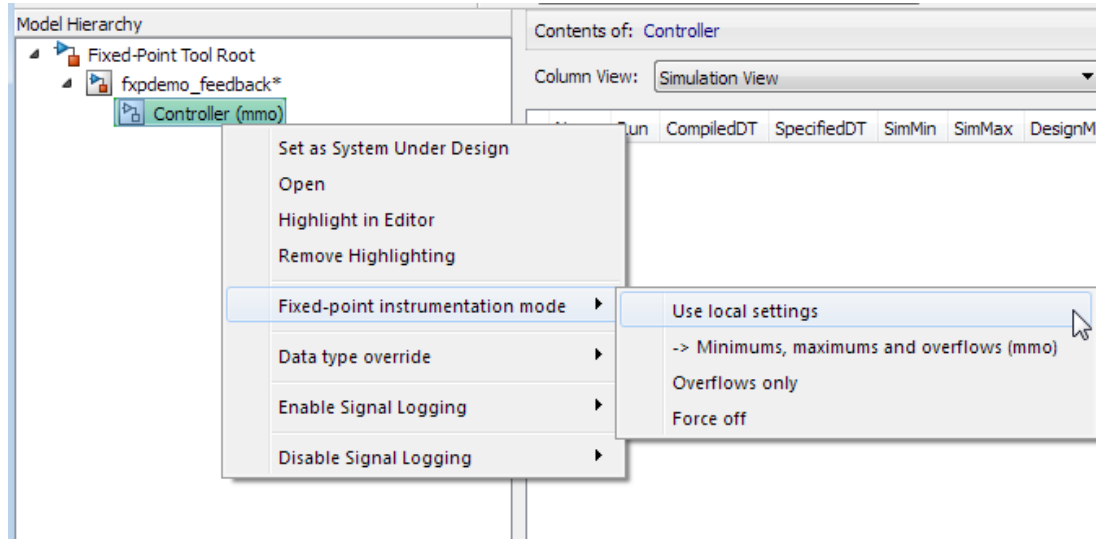
The conversion of a model from floating point to fixed point requires configuring fixed-point instrumentation and data type overrides. However, leaving these settings on after the conversion can lead to unexpected results. If you do not have the Fixed-Point Designer software, you can work with a model containing Simulink blocks with fixed-point settings by turning off fixed-point instrumentation and setting data type override to scaled doubles.

Control Instrumentation Settings

The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the fixed-point tool. These ranges are used to propose data types for the model. When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

1. From the model **Analysis** menu, select **Fixed-Point Tool**.
2. Under **System under design**, click **Continue**.
3. In the Model Hierarchy pane, the Fixed-Point Tool denotes systems that currently have instrumentation turned on with `(mmo)`, or `(o)`. Right-click the system in the model hierarchy and, under `Fixed-point instrumentation mode`, select the mode you want your model to use.

   If you do not have the Fixed-Point Designer software, select `Force off`.

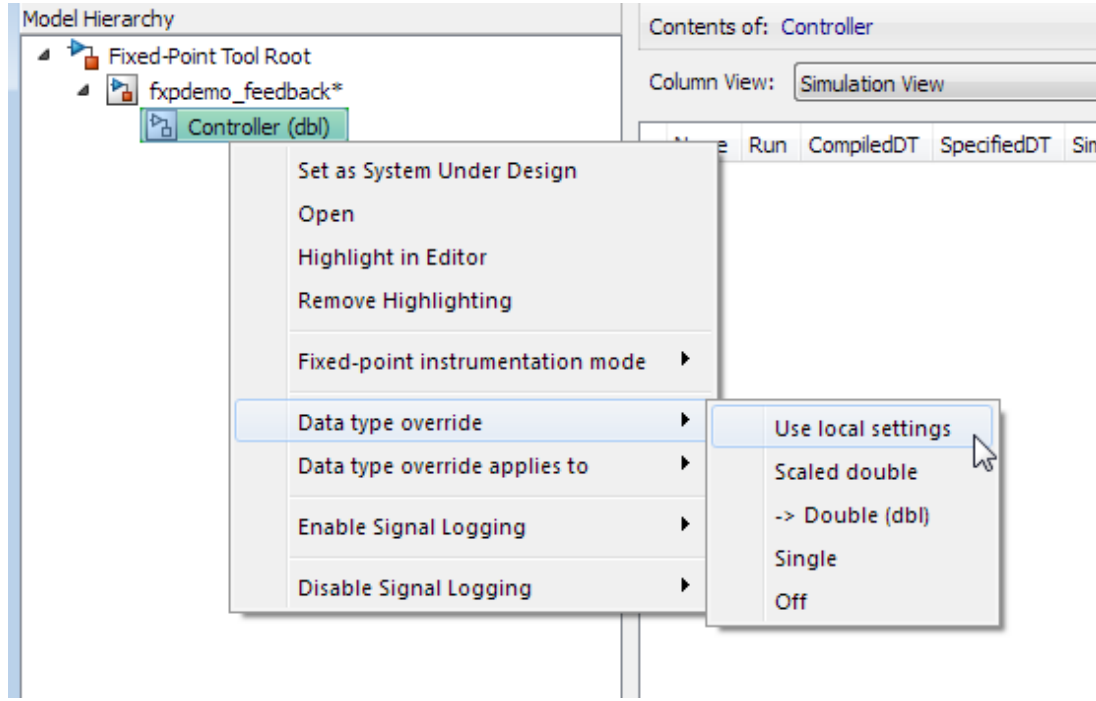


Control Data Type Override

Use data type override to simulate your model using double, single, or scaled double data types. If you do not have Fixed-Point Designer software, you can still configure data type override settings to simulate a model that specifies fixed-point data types. Using this setting, the software temporarily overrides fixed-point data types with floating-point data types during simulation. Turn off data type override to observe the true behavior of your model.

1. From the model **Analysis** menu, select **Fixed-Point Tool**.
2. Under **System under design**, click **Continue**.
3. In the Model Hierarchy pane, the Fixed-Point Tool denotes systems that currently have data type override turned on with `(dbl)`, `(sgl)`, or `(scl)`. Right-click the system in the Model Hierarchy pane and under `Data type override`, select the mode you want your model to use.

   To observe the true behavior of your model, set data type override to `Use local settings` or `Force off`. If you do not have the Fixed-Point Designer software, and would like to simulate a model that uses fixed-point data types, select `Double` or `Single`.



More About

- "Share Fixed-Point Models" on page 57-33

Specify Fixed-Point Data Types

The Simulink software allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See "Overriding Fixed-Point Specifications" on page 57-38 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

Note: You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in "Specifying a Fixed-Point Data Type" on page 57-43.

Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with the Fixed-Point Designer software. However, even if you do not have Fixed-Point Designer software, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode, the Simulink software temporarily overrides fixed-point data types with floating-point data types when simulating the model.

Note: If you use fi objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set fipref to prevent the checkout of a Fixed-Point Designer license.

To simulate a model without using Fixed-Point Designer:

1. In the Simulink Editor, select **Analysis** > **Fixed-Point Tool**.

   The Fixed-Point Tool opens.
2. Under **System under design**, click **Continue**.
3. In the Model Hierarchy pane, right-click the system.
   - Set `Fixed-point instrumentation mode` to `Force off`.
   - Set `Data type override` to `Double` or `Single`.
   - Set `Data type override applies to` `All numeric types`.
4. If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

   For example, at the MATLAB command line, enter:

   ```
   p = fipref('DataTypeOverride', 'TrueDoubles', ...
    'DataTypeOverrideAppliesTo', 'AllNumericTypes');
   ```

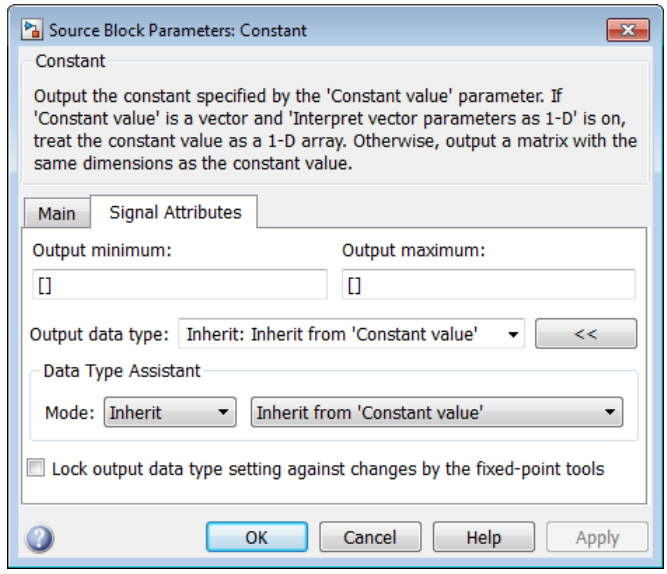
- “Data Types Supported by Simulink” on page 57-5

Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** pane of the Constant block dialog box shown here.



You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

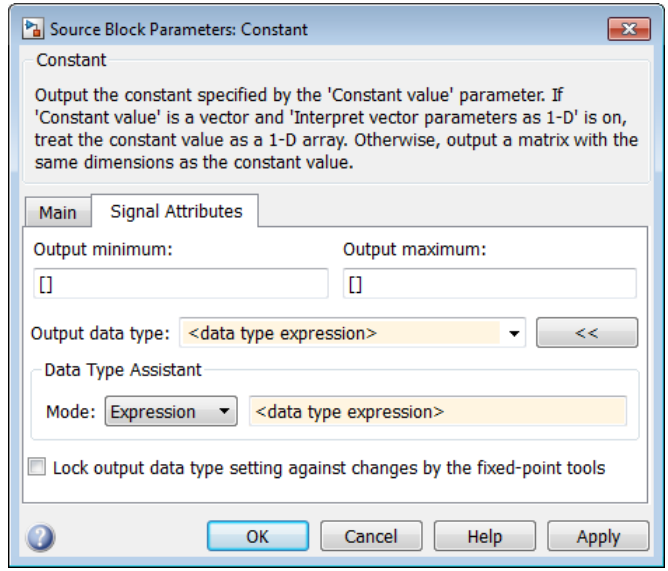
- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button to hide a visible assistant.

Use the **Data Type Assistant** to specify a data type as follows:

1. In the **Mode** field, select the category of data type that you want to specify. In general, the options include the following:

Mode	Description
`Inherit`	Inheritance rules for data types
`Built in`	Built-in data types
`Fixed point`	Fixed-point data types
`Enumerated`	Enumerated data types
`Bus object`	Bus object data types
`Expression`	Expressions that evaluate to data types

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to `Expression` causes the `Constant` block dialog box to appear as follows.



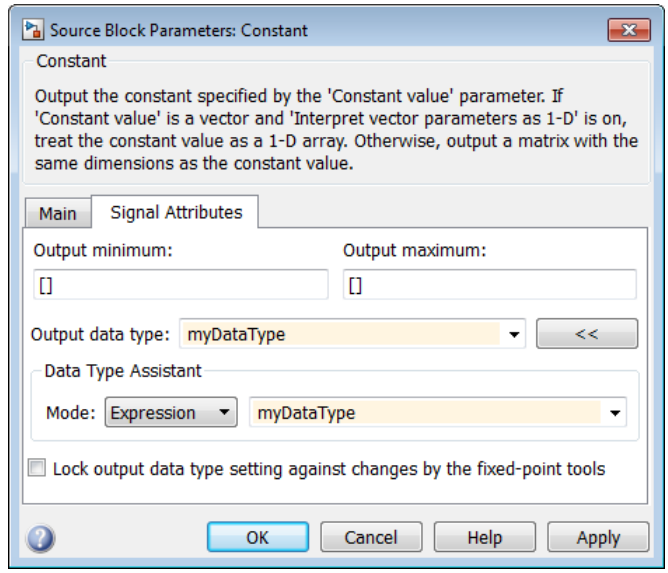
2 In the field that is to the right of the **Mode** field, select or enter a data type.

For example, suppose that you designate the variable `myDataType` as an alias for a `single` data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering the following commands:

```
myDataType = Simulink.AliasType
```

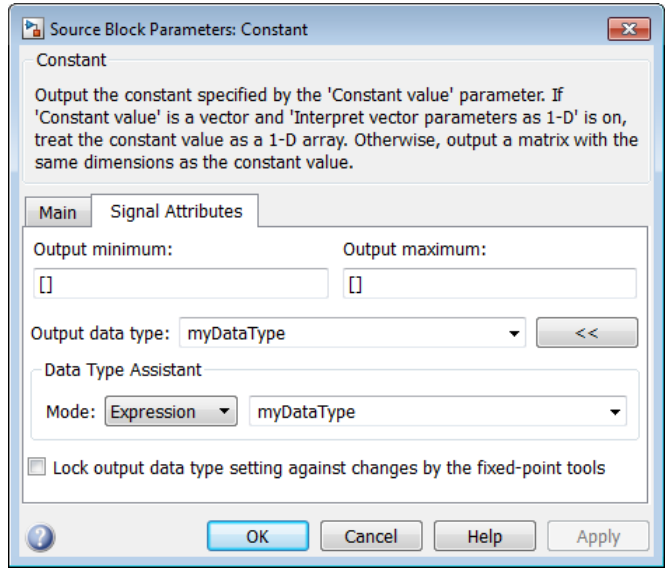
```
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.



3 Click the **OK** or **Apply** button to apply your changes.

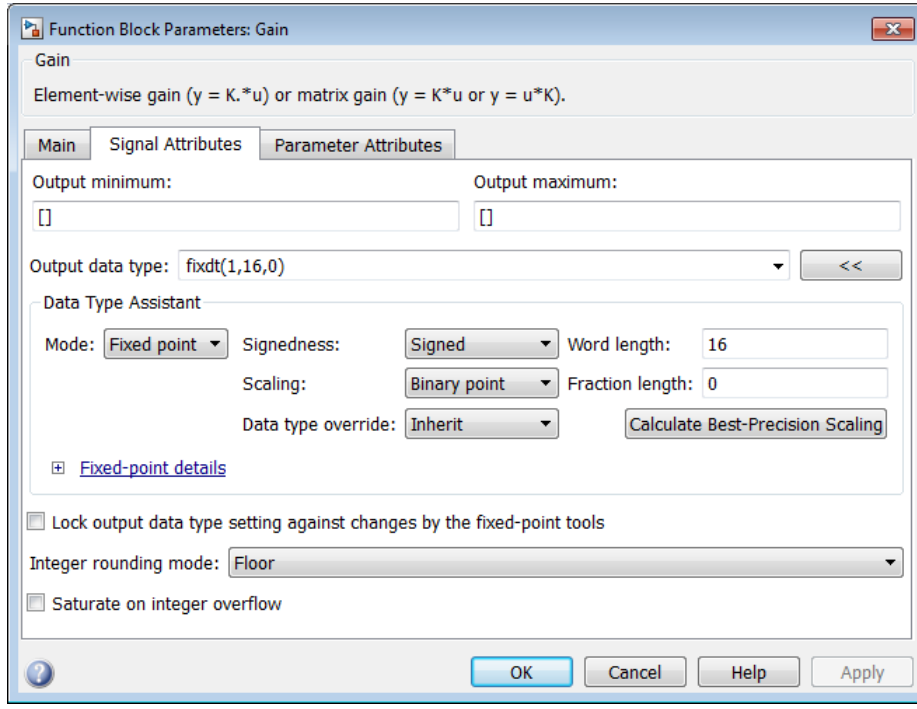
The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. In the following example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.



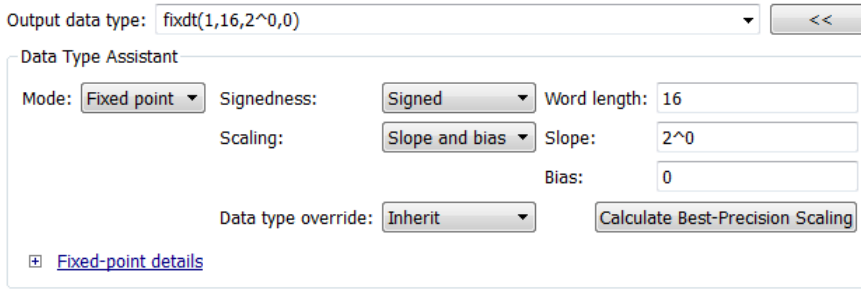
For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 57-9. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant”.

Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is `Fixed point`, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For a detailed discussion about fixed-point data, see “Fixed-Point Basics in MATLAB”. For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.



If the **Scaling** is `Slope and bias` rather than `Binary point`, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:



You can use the Data Type Assistant to set these fixed-point properties:

Signedness

Specify whether you want the fixed-point data to be `Signed` or `Unsigned`. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is `Signed`.

Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 32. The default bit size is 16.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is `Binary point` scaling. You can select one of two scaling modes:

Scaling Mode	Description
`Binary point`	If you select this mode, the Data Type Assistant displays the **Fraction Length** field, which specifies the binary point location. Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:  The default binary point is 0.
`Slope and bias`	If you select this mode, the Data Type Assistant displays fields for entering the **Slope** and **Bias**. Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter

Scaling Mode	Description
	slope and bias as expressions that contain parameters you define in the MATLAB workspace.

Note Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

For more information about fixed-point scaling, see "Scaling".

Data type override

When the **Mode** is `Built in` or `Fixed point`, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal. The default behavior is `Inherit`.

Data Type Override Mode	Description
`Inherit` (default)	Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.
`Off`	Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

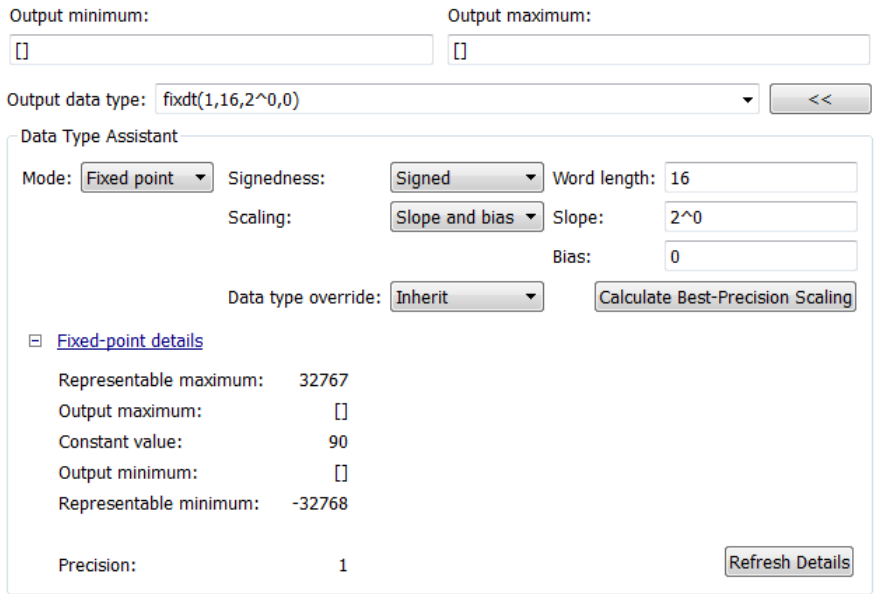
The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both `Binary point` and `Slope and bias` scaling, based on the specified minimum and maximum values. The Simulink software displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see "Constant Scaling for Best Precision".

Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:



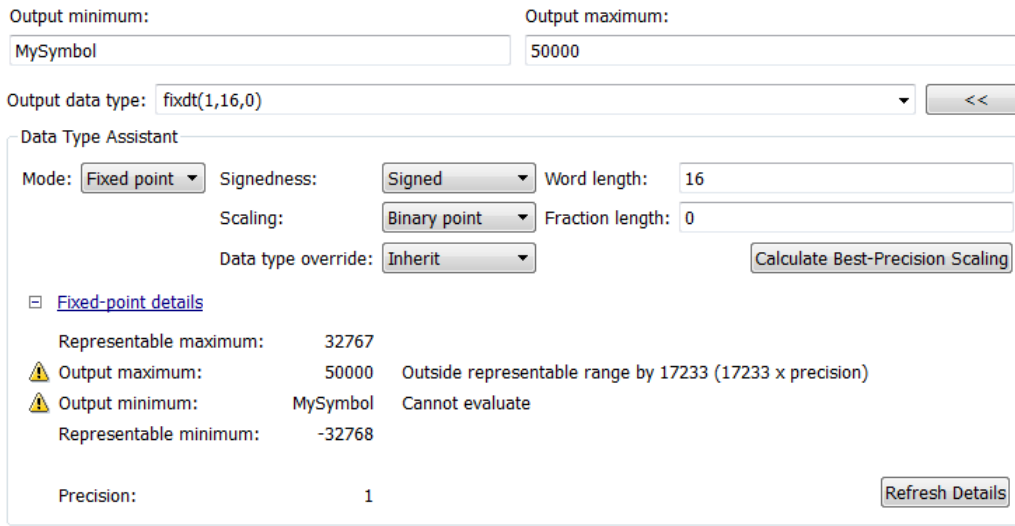
The rows labeled `Output minimum` and `Output maximum` show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See “Signal Ranges” on page 62-41 and “Control Block Parameter Value Ranges” on page 34-56 for more information.

The rows labeled `Representable minimum`, `Representable maximum`, and `Precision` always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant. For information about these three quantities, see “Fixed-Point Basics in MATLAB”.

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as `Unknown`.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:



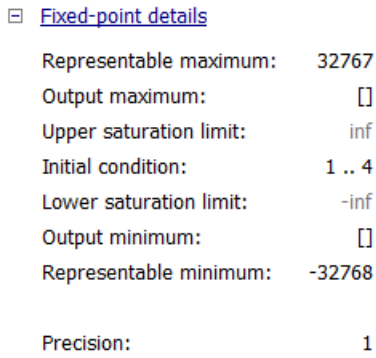
The row labeled `Output minimum` shows the error `Cannot evaluate` because evaluating the expression `MySymbol`, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully, the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define `MySymbol` in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**,

the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for `Output maximum`, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block **Signal Attributes** tab, the subpane can look like this:



The values displayed for `Upper saturation limit` and `Lower saturation limit` are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

To conserve space, `Initial condition` displays the smallest value and the largest value in the vector or matrix, using ellipsis to represent the other values. The underlying definition of the vector or matrix is unaffected.

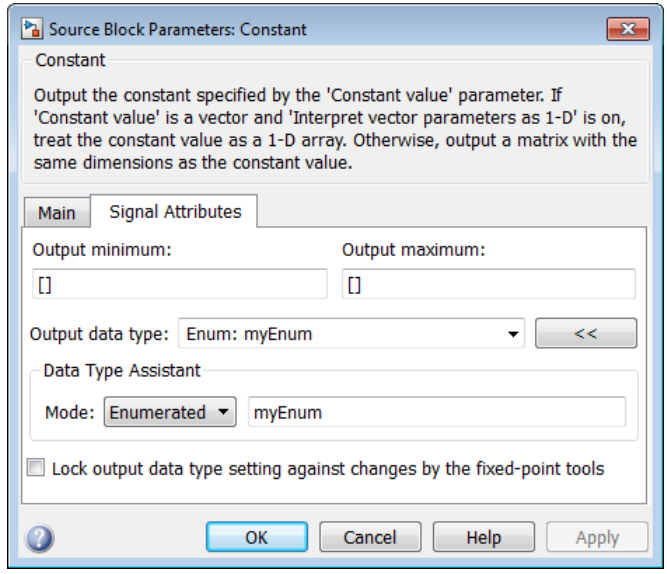
Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling”.

Specify an Enumerated Data Type

You can specify an enumerated data type by selecting the `Enum: <class name>` option and specify an enumerated object.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the `Enumerated` option and specify an enumerated object.

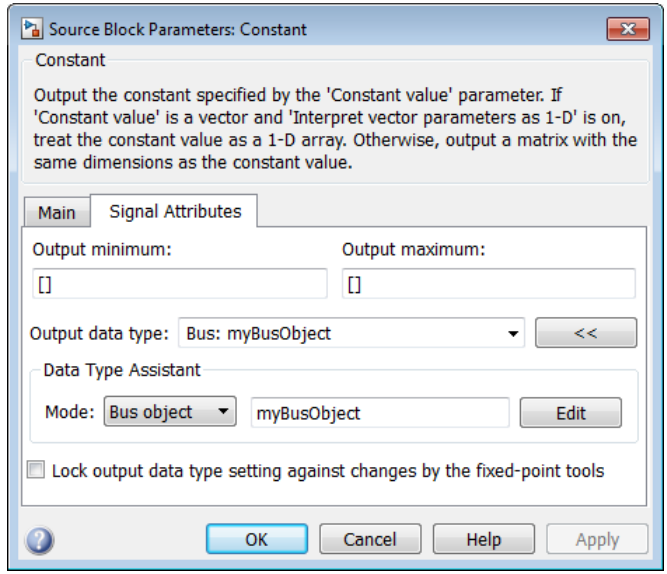


For details about enumerated data types, see “Data Types”.

Specify a Bus Object Data Type

The blocks listed in the section called “Data Types for Bus Signals” on page 57-53 support your specifying a bus object as a data type. For those blocks, in the **Data type** parameter, select the `Bus: <object name>` option and specify a bus object. You cannot use the `Expression` option to specify a bus object as a data type for a block.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the `Bus` option and specify a bus object.



You can specify a bus object as the data type for data objects such as `Simulink.Signal`, `Simulink.Parameter`, and `Simulink.BusElement`. In the Model Explorer, in Properties dialog box for a data object, in the **Data type** parameter, select the `Bus: <object name>` option and specify a bus object. You can also use the `Expression` option to specify a bus object.

For more information on specifying a bus object data type, see “Associate Bus Objects with Simulink Blocks” on page 63-28

Data Types for Bus Signals

A bus object (`Simulink.Bus`) specifies the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

You can specify a bus object as a data type for the following blocks:

- `Bus Creator`
- `Constant`
- `Data Store Memory`
- `Inport`
- `Outport`
- `Signal Specification`

You can specify a bus object as a data type for the following classes:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 57-50 for information about how to specify a bus object as a data type for blocks and classes.

“Handle Versus Value Classes” on page 57-69
“Compare Data Objects” on page 57-71
“Create Persistent Data Objects” on page 57-71

You can create *data objects* to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called *data class packages* contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 57-73.

Data Class Naming Conventions

Simulink uses dot notation to name data classes:

package.class

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package *qualifies* the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myclass` interchangeably to refer to the same class.

Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object to specify the **Gain** parameter of a `Gain` block:

1. Create a parameter object. For example, create an object using the built-in package `Simulink`.

   ```
   myParam = Simulink.Parameter;
   ```

2. Assign a numeric value to the `Value` property.

   ```
   myParam.Value = 15.23;
   ```

3. Specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the parameter data type as `single`, use the `DataType` object property.

   ```
   myParam.DataType = 'single';
   ```

4. In a block dialog box, specify the value of a parameter as `myParam`. For example, in a `Gain` block dialog box, specify **Gain** as `myParam`.

   During simulation, the **Gain** parameter uses the value `single(15.23)`.

Use Signal Objects

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

1. Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

   ```
   mySig = Simulink.Signal;
   ```

2. Specify the signal characteristics by adjusting the object properties. For example, to specify the signal data type as `boolean`, use the `DataType` object property.

   ```
   mySig.DataType = 'boolean';
   ```

3. In the Signal Properties dialog box for the signal in the model, specify **Signal name** as `mySig`. Click **Apply**.
4. Select the check box next to **Signal name must resolve to Simulink signal object**.

   This option forces the model signal to use the properties that the signal object `mySig` defines. To learn how to control the way that signal names resolve to signal objects, see "Symbol Resolution" on page 4-97.

You can use a signal object to control the characteristics of a block state, such as that of the `Discrete-Time Integrator` block.

1. Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

   ```
   myState = Simulink.Signal;
   ```

2. Specify the state characteristics by adjusting the object properties. For example, to specify the state data type as `int16`, use the `DataType` object property.

   ```
   myState.DataType = 'int16';
   ```

3. In a block dialog box, on the **State Attributes** tab, specify **State name** as `myState`. Click **Apply**.
4. Select the check box next to **State name must resolve to Simulink signal object**.

Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have

a `DataType` property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

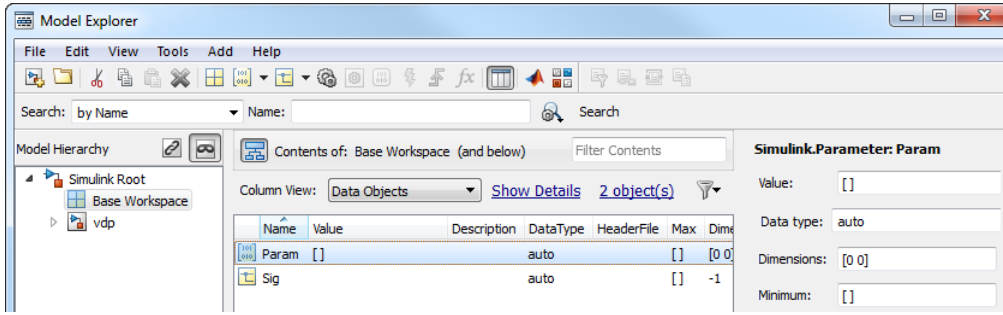
You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).



You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see “Model Explorer: Contents Pane” on page 12-19). To edit a property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;
obj.property = value;
```

where *obj* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see "Handle Versus Value Classes" on page 57-69), PROPERTY is the property's name, and VALUE is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of `Simulink.AliasType`) and sets its base type to `uint8`:

```
gain = Simulink.AliasType;
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

Create Parameter Object with Specific Numeric Data Type

To create a parameter object that uses a specific numeric data type, specify the `Value` property using a `double` number. Specify the `DataType` property using a string. Simulation and code generation cast that number in the `Value` property to the numeric data type that you specify in the `DataType` property.

For example, this code creates a parameter object `myParam` with numeric value `18.25` and numeric data type `single`.

```
myParam = Simulink.Parameter;
myParam.Value = 18.25;
myParam.DataType = 'single';
```

Create Data Objects from Built-In Data Class Package `Simulink`

The built-in package `Simulink` defines two data object classes `Simulink.Parameter` and `Simulink.Signal`. You can create these data objects using the user interface or programmatically.

Create Data Objects

1. In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
2. On the toolbar, click the arrow next to Add Parameter or Add Signal . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

3 To create more objects, click Add Parameter or Add Signal.

Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.
myParam = Simulink.Parameter(15.23);

% Create a Simulink.Signal object named mySig.
mySig = Simulink.Signal;
```

Convert Numeric Variable into Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace
myVar = 5;
/* Create data object and assign variable value
myObject = Simulink.Parameter(myVar);
```

Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define custom storage classes and memory sections in the package. For more information about creating a data class package, see “Define Data Classes” on page 57-73.

Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.

2 Click the arrow next to Add Parameter or Add Signal and select **Customize class lists**.

3. In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
4. Click the arrow next to Add Parameter or Add Signal. Select the class for the data object that you want to create. For example, select **myPackage Parameter** or **myPackage Signal**.

   A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.
5. To create more data objects from the package `myPackage`, click Add Parameter or Add Signal again.

Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named
% myParam whose value is 15.23.
myParam = myPackage.Parameter(15.23);

% Create a myPackage.Signal object named mySig.
mySig = myPackage.Signal;
```

Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box or a block dialog box, you can efficiently create a signal or parameter data object in a workspace or data dictionary.

Create Parameter Object from Block Dialog Box

1. In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
2. Right-click the block parameter edit field. Select **Create Variable**.
3. In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

   Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.

4 Specify **Location** as `Base Workspace` and click **Create**.

   You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

5 In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

   The parameter object `myParam` appears in the base workspace.

6 In the block parameter dialog box, click **OK**.

Create Signal Object from Signal Properties Dialog Box

1 In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.

2 Right-click the **Signal name** edit field. Select **Create Variable**.

3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

   Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.

4 Specify **Location** as `Base Workspace` and click **Create**.

   You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

5 In the dialog box that opens, configure the data object properties and click **OK**.

   The signal object `mySig` appears in the base workspace.

6 In the Signal Properties dialog box, select the check box next to **Signal name must resolve to Simulink signal object** and click **OK**.

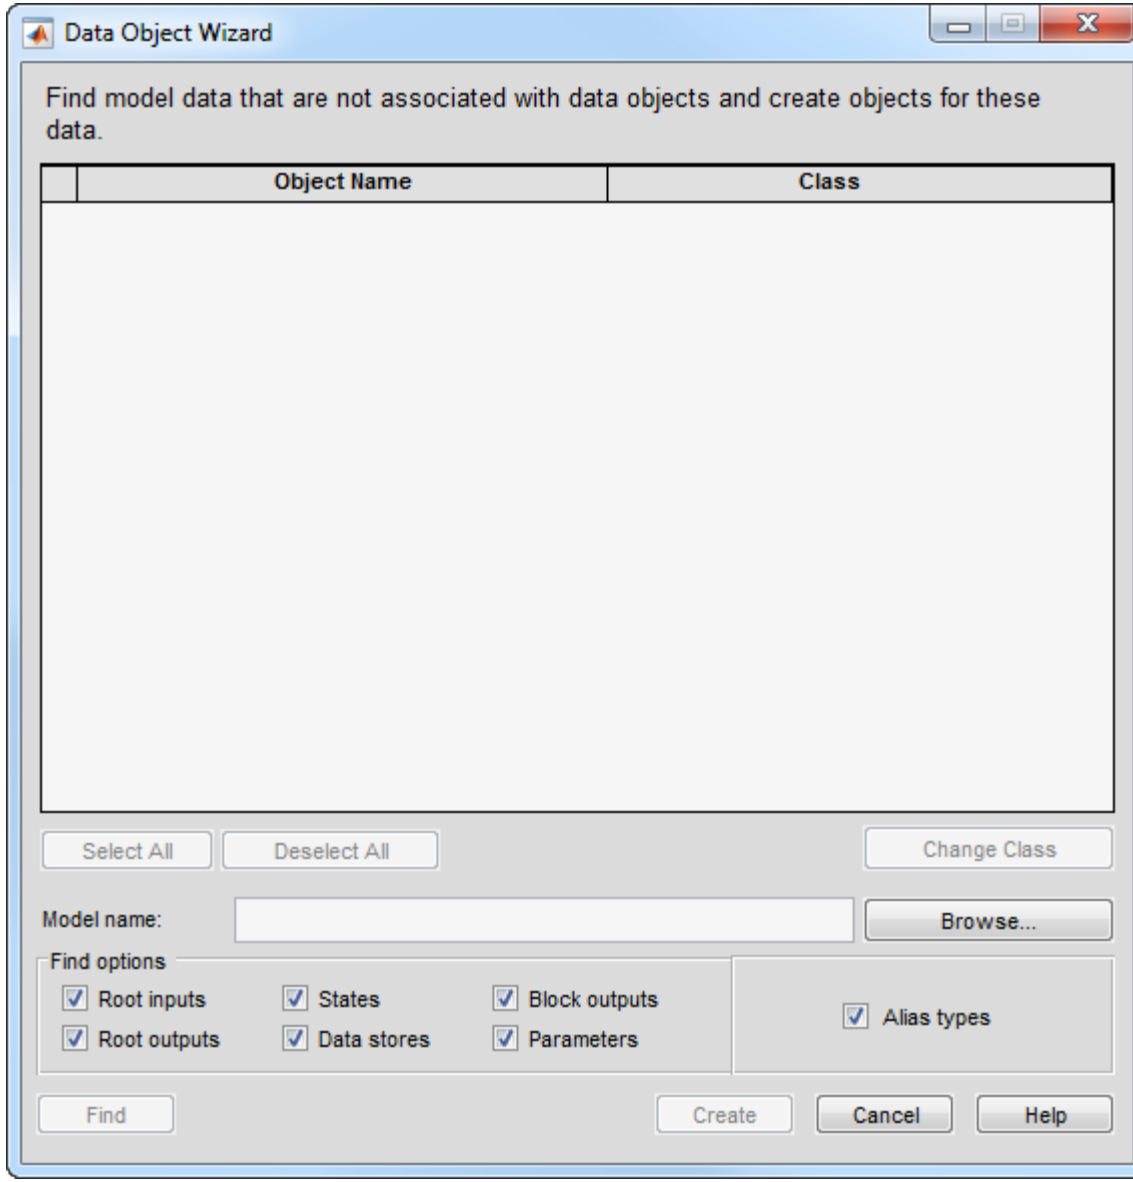
Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
- Numeric value for parameter objects.
- Data type. For signal objects, includes alias types such as `Sumlink.AliasType` and `Simulink.NumericType`.

1 In the Simulink Editor, select **Code** > **Data Objects** > **Data Object Wizard**.



2 In the **Model name** box, enter the name of the model that you want to search.

By default, the box contains the name of the model from which you opened the wizard.

3 Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

Option	Description
Root inputs	Named signals from root-level `Inport` blocks.
Root outputs	Named signals from root-level `Outport` blocks.

States	States associated with these discrete blocks:
	`Discrete Filter`
	`Discrete State-Space`
	`Discrete-Time Integrator`
	`Discrete Transfer Fcn`
	`Discrete Zero-Pole`
	`Memory`
	`PID Controller`
	`PID Controller (2DOF)`
	`Unit Delay`

Data stores	Data stores. For more information about data stores, see "Local and Global Data Stores" on page 60-3 .
Block outputs	Named signals whose sources are non-root-level blocks.

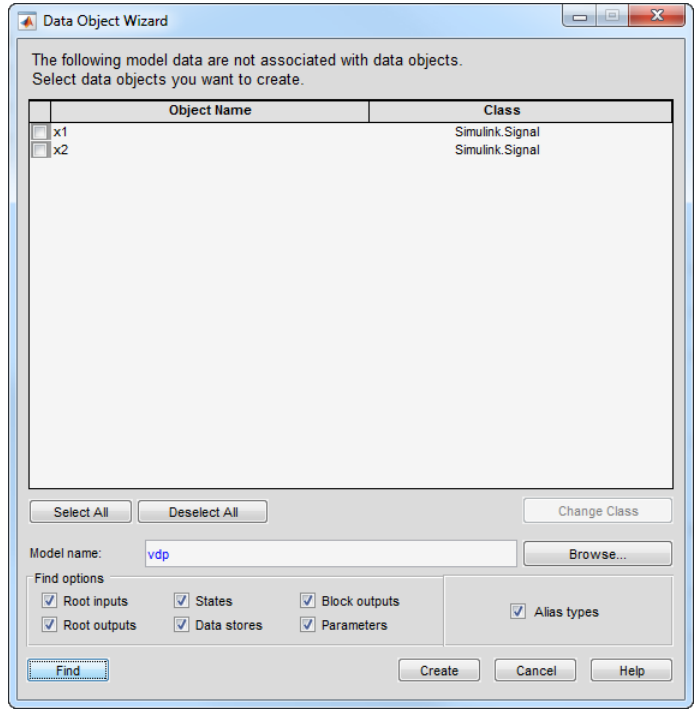
Parameters	• Numeric parameters, for example the parameters in these blocks:
	`Constant`
	`Gain`
	`Relay`
	• Stateflow data with **Scope** set to `Parameter`.
	For more information, see "Share Simulink Parameters with Charts" in the Stateflow documentation.

Alias types	Data type replacement names that you specify in **Configuration Parameters > Code Generation > Data Type Replacement**. If you have an Embedded Coder license, the Data Object Wizard creates `Simulink.AliasType` objects for these data type replacement names. For more information about data type

Option	Description
	replacement, see “Data Type Replacement” in the Embedded Coder documentation.

4 Click **Find**.

The data object table displays the proposed objects.



5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select `Customize class lists`. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.
- On the toolbar, click the arrow next to Add Parameter or Add Signal .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

  A parameter or signal object appears in the selected workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

  The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.

7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters** > **Diagnostics** > **Data Validity** > **Signal resolution**.

- If you set the parameter to `Explicit only`, the wizard forces the corresponding signals in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box.
- If you set the parameter to `Explicit and implicit` or `Explicit and warn implicit`, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** for any signals.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitsignalresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 4-100.

Data Object Wizard Troubleshooting

The Data Object Wizard does not propose creation of data objects for these entities in a model:

- Multiple separate signals that have the same name.
- A signal with the same name as a variable used in a block parameter.
- A signal that lacks a single contiguous source block.
- A signal whose source block is commented out or commented through.
- Data items that are rendered inactive by `Variant Source` and `Variant Sink` blocks. The wizard proposes objects only for data items that are associated with active blocks.

Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

1. Create a new MATLAB script file.
2. Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two `Simulink` data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass ='Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

3. Run the script file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`
- `xlsread`
- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class `A` defines a method called `setName` that assigns a name to an instance of `A`. Further, suppose the MATLAB workspace contains an instance of A assigned to the variable `obj`. Then, you can use either of the following statements to assign the name `'foo'` to `obj`:

```
obj.setName('foo');
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. The Simulink software determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

Note: Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name, which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 57-69).

Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

About Value Classes

The constructor for a *value* class (see “Constructors” on page 57-69) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
x = Simulink.NumericType;
y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
x = Simulink.Parameter;
y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables x and y both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
x.Description = 'input gain';
y.Description
```

```
ans =
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

You can determine whether a variable is assigned to an instance of a class or to a handle to that class by displaying the variable at the MATLAB command line. MATLAB appends the text `(handle)` to the name of the object class in the value display, e.g.,

```
>> gain = Simulink.Parameter
```

```
gain =

Simulink.Parameter (handle)
          Value: []
         CoderInfo: [1x1 Simulink.CoderInfo]
    Description: ''
       DataType: 'auto'
            Min: []
            Max: []
           Unit: ''
     Complexity: 'real'
     Dimensions: [0 0]
```

Copy Handle Classes

Use the copy method of a handle class to create copies of instances of that class. For example, `Simulink.ConfigSet` is a handle class that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (1) if all of the values are the same or false (0) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
result = isequal(A,B)
```

```
result =

     1
```

Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Store the objects in a data dictionary or model workspace. To decide where to permanently store model data, see “Determine Where to Store Data for Simulink Models” on page 57-78.

- Use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB base workspace in the same or a later session. Configure the model to load the objects from the MAT-file or a script file when the model loads.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file. Then use either the script or a load command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved, Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

- Block Parameters
- “What Is a Data Dictionary?” on page 61-2
- “Symbol Resolution” on page 4-97

Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define custom storage classes.

Use an example to define data classes

1. View the `+SimulinkDemos` data class package in the folder *`matlabroot`*`/toolbox/simulink/simdemos/dataclasses` (open).

   This package contains predefined data classes.
2. Copy the folder to the location where you want to define your data classes.
3. Rename the folder `+mypkg` and add its parent folder to the MATLAB path.
4. Modify the data class definitions.

Manually define data class

1. Create a package folder `+mypkg` and add its parent folder to the MATLAB path.
2. Create class folders `@Parameter` and `@Signal` inside `+mypkg`.

   Note: Simulink requires data classes to be defined inside `+Package/@Class` folders.
3. In the `@Parameter` folder, create a MATLAB file `Parameter.m` and open it for editing.
4. Define a data class that is a subclass of `Simulink.Parameter` using MATLAB class syntax.

   ```
   classdef Parameter < Simulink.Parameter

   end % classdef
   ```

To use a custom class name other than `Parameter` or `Signal`, name the class folders using the custom name. For example, to define a class `mypkg.myParameter`:

- Define the data class as a subclass of `Simulink.Parameter` or `Simulink.Signal`.

  ```
  classdef myParameter < Simulink.Parameter

  end % classdef
  ```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
 properties % Unconstrained property type
  Prop1 = [];
 end

 properties(PropertyType = 'logical scalar')
  Prop2 = false;
 end

 properties(PropertyType = 'char')
  Prop3 = '';
 end

 properties(PropertyType = 'char',...
      AllowedValues = {'red'; 'green'; 'blue'})
  Prop4 = 'red';
 end
end % classdef
```

Note: The MATLAB editor does not recognize the attributes `PropertyType` and `AllowedValues`, because they are only defined for Simulink data classes. You can suppress `mlint` warnings about these unrecognized attributes by right-clicking the attribute in the MATLAB editor and selecting **Suppress "Unknown attribute name '...'" > In This File**.

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

Property Type	Syntax
Double number	`properties(PropertyType = 'double scalar')`

Property Type	Syntax
int32 number	`properties(PropertyType = 'int32 scalar')`
Logical number	`properties(PropertyType = 'logical scalar')`
String (char)	`properties(PropertyType = 'char')`
String with limited set of allowed values	`properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'})`

Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```
classdef Parameter < Simulink.Parameter
 methods
  function obj = Parameter(optionalValue)
   if (nargin == 1)
    obj.Value = optionalValue;
   end
  end
 end % methods
end % classdef
```

Optional: Define custom storage classes

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

1. In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

   ```
   classdef Parameter < Simulink.Parameter
    methods
     function setupCoderInfo(obj)
      useLocalCustomStorageClasses(obj, 'mypkg');

      obj.CoderInfo.StorageClass = 'Custom';
   ```

```
  end
 end % methods
end % classdef
```

2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

3 Define custom storage classes.

Optional: Define custom attributes for custom storage classes

1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs`folder, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.

2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a custom storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'char')
  AlternateName = '';
 end
end % classdef
```

3 Override the default implementation of the `isAddressable` method to determine whether the custom storage class is writable.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
  properties(PropertyType = 'logical scalar')
   IsAlternateNameInstanceSpecific = true;
  end

  methods
   function retVal = isAddressable(hObj, hCSCDefn, hData)
    retVal = false;
   end
  end % methods
end % classdef
```

4 Override the default implementation of the `getInstanceSpecificProps` method.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder *`matlabroot`*`\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

Note: This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

Note: In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'char')
  GetFunction = '';
  SetFunction = '';
 end

 methods
  function retVal = getIdentifiersForInstance(hCSCAttrib,...
 hCSCDefn, hData, identifier)
    retVal = struct('GetFunction',...
 hData.CoderInfo.CustomAttributes.GetFunction, ...
    'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
  end%
 end % methods
end % classdef
```

6 If you are using grouped custom storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder *`matlabroot`*`\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

Determine Where to Store Data for Simulink Models

You can store, partition, and share model data in a location that is appropriate for your design. This data can include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Data types
- Model configuration sets
- Simulation input and output data

Choose the appropriate storage locations to more easily manage the data.

In this section...
"Types of Data" on page 57-78
"Store Data for Your Design" on page 57-79
"Storage Locations" on page 57-81

Types of Data

The storage location that you choose can depend on the nature of the data.

- *Simulation data* is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation imports through `Inport` and `From Workspace` blocks. A simulation can generate output data through `Outport` blocks, `To Workspace` blocks, and logged signals.

  You can store simulation data for your current session in the base workspace. To permanently store the data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see "Comparison of Signal Loading Techniques" on page 59-105 and "Export Simulation Data" on page 59-3.
- *Design data* is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- *Configuration sets* are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

  To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage data for your design.

Design	Description	Data Storage Techniques
Rapid prototyping and model experimentation	You want to create temporary data, such as variables to specify numeric block parameters, while you learn to use Simulink. You want to experiment with modeling techniques. You do not need to permanently store	Store data in the base workspace so you can quickly create and change the data.

Design	Description	Data Storage Techniques
	the data that you create.	
Standalone model	You have a single model that does not depend on other systems for data. The model stands alone because it is not a piece of a larger system.	Store data in the model workspace. Use a data dictionary to store data that you cannot store in the model workspace. Alternatively, store all of the model data in a data dictionary. If you use a dictionary, you can partition the data by using referenced dictionaries.
Standalone hierarchy of referenced models	You have a hierarchy of referenced models that does not depend on other systems for data. The hierarchy stands alone because it is not a piece of a larger system.	Store local model data in each model workspace. Store data that the models share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the hierarchy to the dictionary. For examples, see “Migrate Model Reference Hierarchy to Use Dictionary” on page 61-7 and Using a Data Dictionary to Manage the Data for a Fuel Control System.

Design	Description	Data Storage Techniques
System of components	One or more teams maintain the components of a system of models. A *component* is a single model or a hierarchy of referenced models that represents a piece of the system.	Store local model data in model workspaces. Store data that the models in a component share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the component to the dictionary. Use additional referenced dictionaries to store data that the components share. For an example, see "Partition Data for Model Reference Hierarchy Using Data Dictionaries" on page 61-36.

Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

Capability	Base Workspace	Model Workspace	Data Dictionary
Data-model linkage	implicit	implicit	✓
Unified interface for defining data	✓	✓	✓
Model-data dependency	✓	✓	✓
Data entry comparison	✓	✓	✓

Capability	Base Workspace	Model Workspace	Data Dictionary
Data entry persistence		✓	✓
Shared data	✓		✓
Data grouping			✓
Change tracking for data entries			✓
Change tracking for configuration sets			✓
Data entry merging and reconciliation			✓
Storage and partitioning of auxiliary data			✓
Requirements linking			✓

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 4-97.

Temporary Data: Base Workspace

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques
- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

Local Data: Model Workspace

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, the objects can use only the `Auto` storage class.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `IsAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 4-86.

Global and Shared Data: Data Dictionary

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, the model does not use variables in the base workspace anymore.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.Bus` objects that you use to define signal interfaces between referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

Note: Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

---

1. This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

   ```
   Simulink.data.upgradeClasses('C:\MyDataClasses')
   ```
   Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

   Note: Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

   `Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

   Note: If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

   ---

2. You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.

3. Resave MAT-files and models that contain level-1 data objects.
4. Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

Note: You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcb, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcb, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcb, 'UserDataPersistent', 'on');
```

Note If persistent UserData for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

Support Limitations for Simulink Software Features

Simulink Design Verifier does not support the following Simulink software features. Avoid using these unsupported features.

Not Supported	Description
Variable-step solvers	The software supports only fixed-step solvers. For more information, see "Choose a Fixed-Step Solver" on page 23-15 in the Simulink documentation.
Callback functions	The software does not execute model callback functions during the analysis. The results that the analysis generates, such as the harness model, may behave inconsistently with the expected behavior. • If a model or any referenced model calls a callback function that changes any block parameters, model parameters, or workspace variables, the analysis does not reflect those changes. • Changing the storage class of base workspace variables on model callback functions or mask initializations is not supported. • Callback functions called prior to analysis, such as the `PreLoadFcn` or `PostLoadFcn` model callbacks, are fully supported.
Model callback functions	The software only supports model callback functions if the `InitFcn` callback of the model is empty.
Algebraic loops	The software does not support models that contain algebraic loops. For more information, see "Algebraic Loops" on page 3-38 in the Simulink documentation.
Masked subsystem initialization functions	The software does not support models whose masked subsystem initialization modifies any attribute of any workspace parameter.
Complex signals	The software supports only real signals.

Not Supported	Description
	For more information, see "Complex Signals" on page 62-15 in the Simulink documentation.
Variable-size signals	The software does not support variable-size signals. A variable-size signal is a signal whose size (number of elements in a dimension), in addition to its values, can change during model execution. For more information, see "Variable-Size Signal Basics" on page 64-2 in the Simulink documentation.
Multiword fixed-point data types	The software does not support multiword fixed-point data types.
Nonzero start times	Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time: • If you do not select the **Reference input model in generated harness** parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis. • If you select the **Reference input model in generated harness** parameter, a `Model` block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the **Start time** parameter to 0.

Not Supported	Description
Nonfinite data	The software does not support nonfinite data (for example, `NaN` and `Inf`) and related operations. In the `Relational Operator` block, the software assigns the output as follows: • If the **Relational operator** parameter is `isFinite`, the output is always 1. • If the **Relational operator** parameter is `isNan` or `isInf`, the output is always 0. In the `MATLAB Function` block, the software assigns the return value as follows: • For the `isFinite` function, the output is always 1. • For the `isNan` and `isInf` functions, the output is always 0.
Concurrent execution	The software does not support models that are configured for concurrent execution.
Signals with nonzero sample time offset	The software does not support models with signals that have nonzero sample time offsets.
Models with no output ports	The software only supports models that have one or more output ports.
Large floating-point constants outside the range `[-realmax/2, realmax/2]`	The use of large floating-point constants can cause out of memory errors or substantial loss of precision. Avoid using such constants if possible.
Symbolic Dimensions	The software does not support symbolic dimensions for test generation, property proving, or design error detection.

More About

- “Support Limitations for Stateflow Software Features” on page 57-102

Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see "Handle Incompatibilities with Automatic Stubbing".

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

Continuous Library

Block	Support Notes
`Derivative`	Not supported
`Integrator`	Not supported and not stubbable
Integrator Limited	Not supported and not stubbable
`PID Controller`	Not supported
`PID Controller (2 DOF)`	Not supported

Block	Support Notes
Second Order Integrator	Not supported and not stubbable
`Second Order Integrator Limited`	Not supported and not stubbable
`State-Space`	Not supported and not stubbable
`Transfer Fcn`	Not supported and not stubbable
`Transport Delay`	Not supported
`Variable Time Delay`	Not supported
`Variable Transport Delay`	Not supported
`Zero-Pole`	Not supported and not stubbable

Discontinuities Library

The software supports all blocks in the Discontinuities library.

Discrete Library

Block	Support Notes
`Delay`	Supported
`Difference`	Supported
`Discrete Derivative`	Supported
`Discrete Filter`	Supported
`Discrete FIR Filter`	Supported
Discrete PID Controller	Supported
Discrete PID Controller (2 DOF)	Supported
`Discrete State-Space`	Not supported
`Discrete Transfer Fcn`	Supported
`Discrete Zero-Pole`	Not supported
`Discrete-Time Integrator`	Supported
`First-Order Hold`	Supported
`Memory`	Supported
`Tapped Delay`	Supported

Block	Support Notes
`Transfer Fcn First Order`	Supported
`Transfer Fcn Lead or Lag`	Supported
`Transfer Fcn Real Zero`	Supported
`Unit Delay`	Supported
`Zero-Order Hold`	Supported

Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

Lookup Tables Library

Block	Support Notes
`Cosine`	Supported
`Direct Lookup Table (n-D)`	Supported
`Interpolation Using Prelookup`	Not supported when: • The **Interpolation method** parameter is `Linear` and the **Number of table dimensions** parameter is greater than `4`. or • The **Interpolation method** parameter is `Linear` and the **Number of sub-table selection dimensions** parameter is not `0`.
`1-D Lookup Table`	Not supported when the **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`.
`2-D Lookup Table`	Not supported when the **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`.
`n-D Lookup Table`	Not supported when: • The **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`. or

Block	Support Notes
	• The **Interpolation method** parameter is `Linear` and the **Number of table dimensions** parameter is greater than 5.
`Lookup Table Dynamic`	Supported
`Prelookup`	Supported
Sine	Supported

Math Operations Library

Block	Support Notes
`Abs`	Supported
`Add`	Supported
`Algebraic Constraint`	Supported
`Assignment`	Supported
`Bias`	Supported
`Complex to Magnitude-Angle`	Not supported
`Complex to Real-Imag`	Supported
`Divide`	Supported
`Dot Product`	Supported
Find Nonzero Elements	Supported
`Gain`	Supported
`Magnitude-Angle to Complex`	Supported

`Math Function`	All signal types support the following **Function** parameter settings.
	
	`conj` `hermitian` `magnitude^2` `mod`
	`rem` `reciprocal` `square` `transpose`
	
	The software does not support the following **Function** parameter settings.
	
	`10^u` `exp` `hypot`

Block	Support Notes		
	`log`	`log10`	`pow`
Matrix Concatenate	Supported		
`MinMax`	Supported		
`MinMax Running Resettable`	Supported		
`Permute Dimensions`	Supported		
`Polynomial`	Supported		
`Product`	Supported		
`Product of Elements`	Supported		
`Real-Imag to Complex`	Supported		
`Reciprocal Sqrt`	Not supported		
`Reshape`	Supported		
`Rounding Function`	Supported		
`Sign`	Supported		
`Signed Sqrt`	Not supported		
`Sine Wave Function`	Not supported		
`Slider Gain`	Supported		
`Sqrt`	Supported		
`Squeeze`	Supported		
`Subtract`	Supported		
`Sum`	Supported		
`Sum of Elements`	Supported		
`Trigonometric Function`	Supported if **Function** is `sin`, `cos`, or `sincos`, and **Approximation method** is `CORDIC`.		
`Unary Minus`	Supported		
Vector Concatenate	Supported		
`Weighted Sample Time Math`	Supported		

Model Verification Library

The software supports all blocks in the Model Verification library.

Model-Wide Utilities Library

Block	Support Notes
`Block Support Table`	Supported
`DocBlock`	Supported
`Model Info`	Supported
`Timed-Based Linearization`	Not supported
`Trigger-Based Linearization`	Not supported

Ports & Subsystems Library

Block	Support Notes
`Atomic Subsystem`	Supported
`Code Reuse Subsystem`	Supported
`Configurable Subsystem`	Supported
`Enable`	Supported
`Enabled Subsystem`	Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values”.
`Enabled and Triggered Subsystem`	Not supported when the trigger control signal specifies a fixed-point data type. Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values”.
`For Each`	Supported with the following limitations: • When For Each Subsystem contains one or more Simulink Design Verifier `Test Condition`,

Block	Support Notes
	`Test Objective`, `Proof Assumption`, or `Proof Objective` blocks, not supported. • When the mask parameters of the `For Each Subsystem` are partitioned, not supported.
`For Each Subsystem`	Supported with the following limitations: • When For Each Subsystem contains one or more Simulink Design Verifier `Test Condition`, `Test Objective`, `Proof Assumption`, or `Proof Objective` blocks, not supported. • When the mask parameters of the `For Each Subsystem` are partitioned, not supported.
`For Iterator Subsystem`	Supported
`Function-Call Feedback Latch`	Supported
`Function-Call Generator`	Supported
`Function-Call Split`	Supported
`Function-Call Subsystem`	Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values”.
`If`	Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for an `If` block.
`If Action Subsystem`	Supported
`Inport`	Supported
`Model`	Supported except for the limitations described in “Support Limitations for Model Blocks”.
`Model Variants`	Supported except for the limitations described in “Support Limitations for Model Blocks”.
`Outport`	Supported
`Resettable Subsystem`	Supported

Block	Support Notes
`Subsystem`	Supported
`Switch Case`	Supported
`Switch Case Action Subsystem`	Supported
`Trigger`	Supported
`Triggered Subsystem`	Not supported when the trigger control signal specifies a fixed-point data type. Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see "Check for Specified Intermediate Minimum and Maximum Signal Values".
`Variant Subsystem`	Not supported when the **Generate preprocessor conditionals** parameter is enabled. Only the active variant is analyzed.
`While Iterator Subsystem`	Supported

Signal Attributes Library

The software supports all blocks in the Signal Attributes library.

Signal Routing Library

Block	Support Notes
`Bus Assignment`	Supported
`Bus Creator`	Supported
`Bus Selector`	Supported
`Data Store Memory`	Supported
`Data Store Read`	Supported
`Data Store Write`	Supported
`Demux`	Supported
`Environment Controller`	Supported

Block	Support Notes
From	Supported
Goto	Supported
Goto Tag Visibility	Supported
Index Vector	Supported
Manual Switch	The Manual Switch block is compatible with the software, but the analysis ignores this block in a model. The analysis does not flag the coverage objectives for this block as satisfiable or unsatisfiable. Model coverage data is collected for the Manual Switch block.
Merge	Supported
Multiport Switch	Supported
Mux	Supported
Selector	Supported
Switch	Supported
Vector Concatenate	Supported

Sinks Library

Block	Support Notes
Display	Supported
Floating Scope	Supported
Outport (Out1)	Supported
Scope	Supported
Stop Simulation	Not supported and not stubbable
Terminator	Supported
To File	Supported
To Workspace	Supported
XY Graph	Supported

Sources Library

Block	Support Notes
`Band-Limited White Noise`	Not supported
`Chirp Signal`	Not supported
`Clock`	Supported
`Constant`	Supported unless **Constant value** is `inf`.
`Counter Free-Running`	Supported
`Counter Limited`	Supported
`Digital Clock`	Supported
`Enumerated Constant`	Supported
`From File`	Not supported. When MAT-file data is stored in MATLAB `timeseries` format, not stubbable.
`From Workspace`	Not supported
`Ground`	Supported
`Inport` (In1)	Supported
`Pulse Generator`	Supported
`Ramp`	Supported
`Random Number`	Not supported and not stubbable
`Repeating Sequence`	Not supported
`Repeating Sequence Interpolated`	Not supported
`Repeating Sequence Stair`	Supported
`Signal Builder`	Not supported
`Signal Generator`	Not supported
`Sine Wave`	Not supported
`Step`	Supported
`Uniform Random Number`	Not supported and not stubbable

User-Defined Functions Library

Block	Support Notes
`Fcn`	Supports all operators except `^`, and supports only the mathematical functions `abs`, `ceil`, `fabs`, `floor`, `rem`, and `sgn`. Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for these blocks.
`Interpreted MATLAB Function`	Not supported
`Level-2 MATLAB S-Function`	For limitations, see “Support Limitations for S-Functions”.
`MATLAB Function`	For limitations, see “Support Limitations for MATLAB for Code Generation”.
`S-Function`	For limitations, see “Support Limitations for S-Functions”.
`S-Function Builder`	For limitations, see “Support Limitations for S-Functions”.
`Simulink Function`	Simulink Function blocks with output arguments that are of bus data-type are not supported. Calls to Simulink Functions across model boundaries are not supported.

More About

- “Support Limitations for Simulink Software Features” on page 57-88
- “Support Limitations for Stateflow Software Features” on page 57-102

Support Limitations for Stateflow Software Features

Simulink Design Verifier does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

In this section...

"ml Namespace Operator, ml Function, ml Expressions" on page 57-102
"C Math Functions" on page 57-102
"Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart" on page 57-103
"Atomic Subchart Input and Output Mapping" on page 57-103
"Recursion and Cyclic Behavior" on page 57-103
"Custom C or C++ Code" on page 57-105
"Machine-Parented Data" on page 57-105
"Textual Functions with Literal String Arguments" on page 57-105

ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. (See "Access Built-In MATLAB Functions and Workspace Data" in the Stateflow documentation.)

C Math Functions

The software supports calls to the following C math functions:

- `abs`
- `ceil`
- `fabs`
- `floor`
- `fmod`
- `labs`
- `ldexp`
- `pow` (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see "Call C Functions in C Charts" in the Stateflow documentation.

Note: For details about automatic stubbing, see "Handle Incompatibilities with Automatic Stubbing".

Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

Note: For information about exported functions, see "Export Stateflow Functions for Reuse" in the Stateflow documentation.

Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

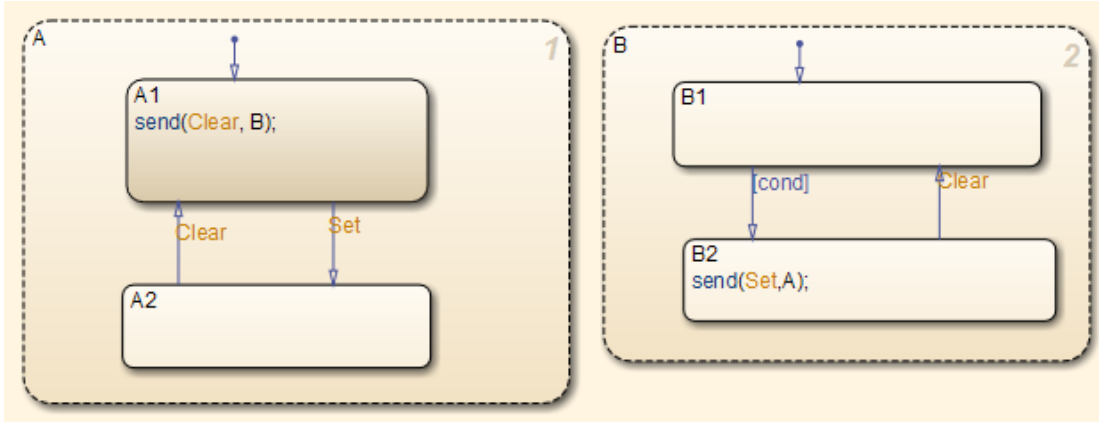
Note: For information about avoiding recursion in Stateflow charts, see "Guidelines for Avoiding Unwanted Recursion in a Chart" in the Stateflow documentation.

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

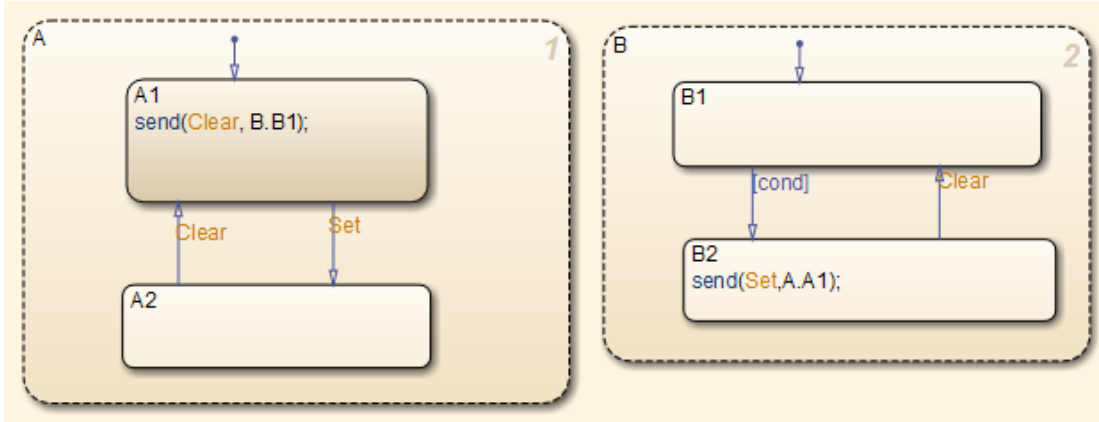
Note: For information about cyclic behavior in Stateflow charts, see "Cyclic Behavior in a Chart" in the Stateflow documentation.

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a `Clear` event to state B, which calls state B2, which broadcasts a `Set` event back to state A, causing the cyclic behavior.



If you change the `send` function calls to use directed event broadcasts so that the Set and Clear events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.



Note: For information about the benefits of directed event broadcasts, see "Broadcast Events to Synchronize States" in the Stateflow documentation.

Custom C or C++ Code

The software does not support custom C or C++ code, which the Stateflow software allows.

Machine-Parented Data

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see "Best Practices for Using Data in Charts" in the Stateflow documentation.

Textual Functions with Literal String Arguments

The software does not support literal string arguments to textual functions in a Stateflow chart.

Enumerations and Modeling

- "Simulink Enumerations" on page 58-2
- "Use Enumerated Data in Simulink Models" on page 58-7

Simulink Enumerations

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in "Enumerations".

The following examples show how to use enumerations in Simulink and Stateflow.

Example	Shows How To Use...
Data Typing in Simulink	Data types in Simulink, including enumerated data types
Modeling a CD Player/Radio Using Enumerated Data Types	Enumerated data types in a Simulink model that contains a Stateflow chart

For information on using enumerations in Stateflow, see "Enumerated Data".

Simulink Constructs that Support Enumerations

- "Overview" on page 58-2
- "Block Support" on page 58-3
- "Class Support" on page 58-4
- "Logging Enumerated Data" on page 58-4
- "Importing Enumerated Data" on page 58-4

Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the

output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See "Enumerated Values in Computation" on page 58-22 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See "Simulink Enumeration Limitations" on page 58-5 for information about certain constructs that could support enumerated types but do not.

Block Support

The following Simulink blocks support enumerated types:

- `Constant` (but `Enumerated Constant` is preferable)
- `Data Type Conversion`
- `Data Type Conversion Inherited`
- `Data Type Duplicate`
- `Display`
- `MATLAB Function`
- `Enumerated Constant`
- `Floating Scope`
- `From File`
- `From Workspace`
- `Inport`
- `Interval Test`
- `Interval Test Dynamic`
- `Multiport Switch`
- `Outport`
- `Probe` (input only)
- `Relational Operator`
- `Relay` (output only)
- `Repeating Sequence Stair`
- `Scope`
- `Signal Specification`

- `Switch`
- `Switch Case`
- `To File`
- `To Workspace`

All members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see "Bus-Capable Blocks" on page 63-25)
- Pass-through blocks:
  - With state, like the `Data Store Memory` and `Unit Delay` blocks.
  - Without state, like the `Mux` block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

Class Support

The following Simulink classes support enumerated types:

- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.AliasType`
- `Simulink.BusElement`

Logging Enumerated Data

Root-level outports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The `From File` block does not support enumerated data. Use the `From Workspace` block instead, combined with some technique for transferring data between a file and a workspace. See "Save Runtime Data from Simulation" for more information.

Importing Enumerated Data

Root-level inports and `From Workspace` blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or

`TimeSeries` object. No interpolation occurs for enumerated values between the specified simulation times. `From File` blocks produce only data of type `double`, so they do not support enumerated types. See "Load Signal Data for Simulation" for more information.

Simulink Enumeration Limitations

- "Enumerations and Scopes" on page 58-5
- "Enumerated Types for Switch Blocks" on page 58-5
- "Nonsupport of Enumerations" on page 58-5

Enumerations and Scopes

When a `Scope` block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the `Scope` block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the `Scope` block is opened.

When a `Floating Scope` block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the `Floating Scope` block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

Enumerated Types for Switch Blocks

The control input of a `Switch` block can be of any data type supported by Simulink software. However, the `u2 ~=0` mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.
- Use a `Relational Operator` block to do the comparison and then feed the Boolean result of this comparison into the control port of the `Switch` block.

Nonsupport of Enumerations

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The `If Action` block might support enumerations, but currently does not do so.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

Use Enumerated Data in Simulink Models

In this section...
"Define Simulink Enumerations" on page 58-7
"Simulate with Enumerations" on page 58-14
"Specify Enumerations as Data Types" on page 58-16
"Get Information About Enumerated Data Types" on page 58-17
"Enumeration Value Display" on page 58-17
"Instantiate Enumerations" on page 58-19
"Enumerated Values in Computation" on page 58-22

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see "Simulink Enumerations" on page 58-2.

For information about generating code with enumerations, see "Use Enumerated Data in Generated Code" in the Simulink Coder documentation.

Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.

Workflow to Define a Simulink Enumeration

1. Create a class definition.
2. Optionally, customize the enumeration.
3. Optionally, save the enumeration in a MATLAB file.

Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an `enumeration` block that specifies enumeration values with underlying integer values.

Consider the following example:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The `enumeration` section specifies three enumerated values.

Enumerated Value	Enumerated Name	Underlying Integer
`Red(0)`	`Red`	`0`
`Yellow(1)`	`Yellow`	`1`
`Blue(2)`	`Blue`	`2`

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.
- Underlying integer values in the `enumeration` section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.

- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See "Select a System Target File" and "Hardware Implementation Pane" for more information.

For more information on superclasses, see "Convert to Superclass Value". For information on how enumeration classes are handled when there is more than one name for an underlying value, see "How to Alias Enumeration Names".

Customize Simulink Enumeration

About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
`getDefaultValue`	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A string containing the name of an enumeration member in the class (see "Instantiate Enumerations" on page 58-19)	Simulation and code generation
`getDescription`	Specifies a description of the enumeration class.	`''`	A string containing the description of the type	Code generation
`getHeaderFile`	Specifies the name of a header file. The method `getDataScope` determines the significance of the file.	`''`	A string containing the name of the header file that defines the enumerated type	Code generation

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
`getDataScope`	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method `getHeaderFile` to specify the generated or included header file that defines the type.	`'Auto'`	One of these strings: `'Auto'`, `'Exported'`, or `'Imported'`	Code generation
`addClassNameToEnum`	Specifies whether to prefix the class name in generated code.	`false`	`true` or `false`	Code generation

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” in the Simulink Coder documentation.

Specify a Default Enumerated Value

Simulink software and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” in the Simulink Coder documentation.

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```
function retVal = getDefaultValue()
  % GETDEFAULTVALUE Specifies the default enumeration member.
  % Return a valid member of this enumeration class to specify the default.
  % If you do not define this method, Simulink uses the first member.
  retVal = ThisClass.EnumName;
end
```

To customize this method, provide a value for *`ThisClass.EnumName`* that specifies the desired default.

- *`ThisClass`* must be the name of the class within which the method exists.
- *`EnumName`* must be the name of an enumerated value defined in that class.

For example:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
  methods (Static)
    function retVal = getDefaultValue()
      retVal = BasicColors.Blue;
    end
  end
end
```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *`ThisClass`* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 58-19 for more information.

Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.
- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see "What Is the MATLAB Search Path?", `addpath`, and `savepath`.

- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

Change and Reload Enumerations

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

If In Base Workspace...	If In Cache...
Do one of the following: • Locate and delete specific obsolete instances. • Delete everything from the workspace by using the `clear` command.	• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect. • Clear functions and close models that are caching instances of the class.

For more information about applying enumeration changes, see "Automatic Updates for Modified Classes".

Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB— for example, in a data dictionary, that you want to import for use within the Simulink environment, you can do so programmatically with calls to the function `Simulink.defineIntEnumType`. This function defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:

- String that describes the enumeration class.
- Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
 enumeration
  Red(0)
  Yellow(1)
  Blue(2)
 end
 methods (Static = true)
  function retVal = getDescription()
   retVal = 'Basic colors...';
  end
  function retVal = getDefaultValue()
   retVal = BasicColors.Blue;
  end
  function retVal = getHeaderFile()
   retVal = 'mybasiccolors.h';
  end
  function retVal = addClassNameToEnumNames()
   retVal = true;
  end
 end
end
```

The following function call defines the same class for use in MATLAB:

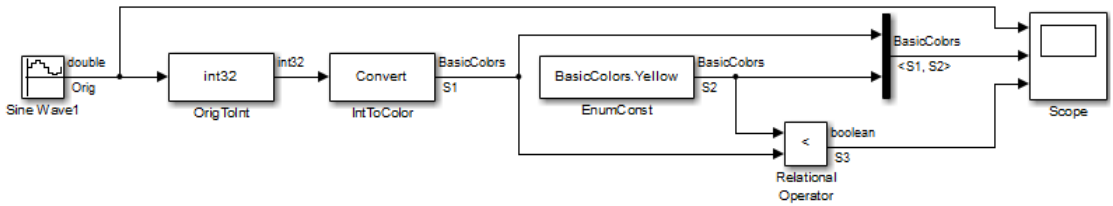
```
Simulink.defineIntEnumType('BasicColors', ...
     {'Red', 'Yellow', 'Blue'}, [0;1;2],...
     'Description', 'Basic colors', ...
     'DefaultValue', 'Blue', ...
     'HeaderFile', 'mybasiccolors.h', ...
     'DataScope', 'Imported', ...
     'AddClassNameToEnumNames', true);
```

Simulate with Enumerations

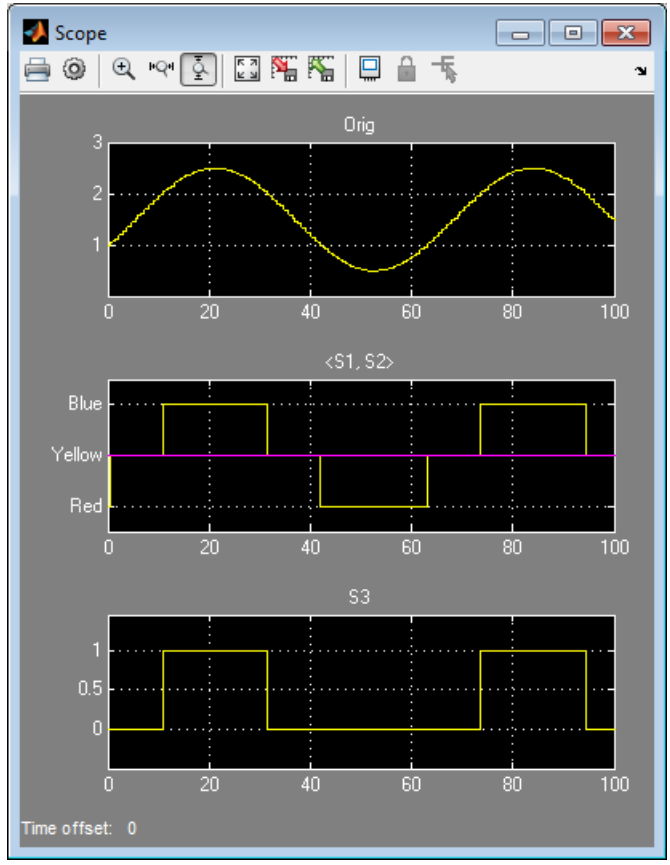
Consider the following enumeration class definition — `BasicColors` with enumerated values `Red`, `Yellow`, and `Blue`, with `Blue` as the default value:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
  methods (Static)
    function retVal = getDefaultValue()
      retVal = BasicColors.Blue;
    end
  end
end
```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in "Enumerated Data". The following Simulink model uses the enumeration defined above:



The output of the model looks like this:



The `Data Type Conversion` block **OrigToInt** specifies an **Output data type** of `int32` and **Integer rounding mode:** `Floor`, so the block converts the `Sine Wave` block output, which appears in the top graph of the `Scope` display, to a cycle of integers: `1`, `2`, `1`, `0`, `1`, `2`, `1`. The `Data Type Conversion` block **IntToColor** uses these values to select colors from the enumerated type `BasicColors` by referencing their underlying integers.

The result is a cycle of colors: `Yellow`, `Blue`, `Yellow`, `Red`, `Yellow`, `Blue`, `Yellow`, as shown in the middle graph. The `Enumerated Constant` block **EnumConst** outputs `Yellow`, which appears in the second graph as a straight line. The `Relational Operator` block compares the constant `Yellow` to each value in the cycle of colors. It outputs `1` (`true`) when `Yellow` is less than the current color, and `0` (`false`) otherwise, as shown in the third graph.

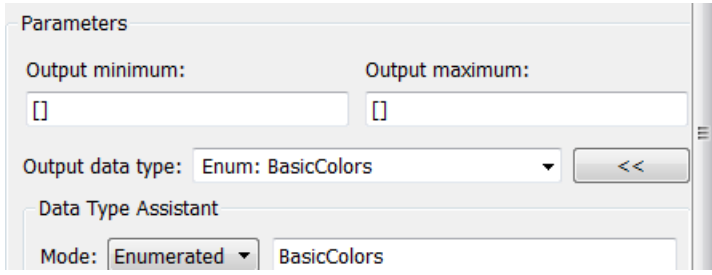
The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See "Specify Enumerations as Data Types" on page 58-16 and "Enumerated Values in Computation" on page 58-22 for more information.

Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix ? or `Enum:` when specifying the enumeration as a data type. You must use the prefix `?` in the MATLAB Command Window. However, you can use either prefix in a Simulink model. `Enum:` has the same effect as the `?` prefix, but `Enum:` is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type `Enum:` followed by the name of an enumeration, or select `Enum: <class name>` from a menu (for example, for the **Output data type** block parameter) , and replace `<class name>`.

To use the Data Type Assistant, set the **Mode** to `Enumerated`, then enter the name of the enumeration. For example, in the previous model, the `Data Type Conversion` block **IntToColor**, which outputs a signal of type `BasicColors`, has the following output signal specification:



You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of `[]`, an error occurs when you update the model. See "Enumerated Values in Computation" on page 58-22 for more information.

Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

Enumeration Value Display

Wherever possible, Simulink software displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in `Scope` and `Floating Scope` blocks.

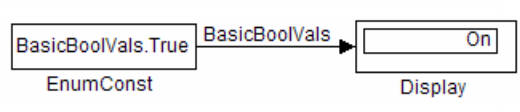
Block...	Affect on Value Display...
`Scope`	When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.
`Floating Scope`	When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a `Scope` block. If the `Floating Scope` block displays mixed data types, no

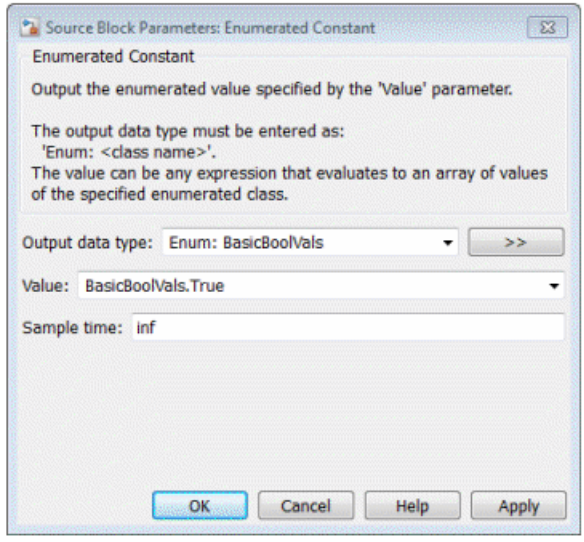
Block...	Affect on Value Display...
	names appear, and any enumerated values are represented by their underlying integers.

Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in "Specify Enumerations as Data Types" on page 58-16. When this occurs, the value on an axis of `Scope` block output or in `Display` block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

```
classdef BasicBoolVals < Simulink.IntEnumType
  enumeration
    On(1)
    Off(0)
    True(1)
    False(0)
  end
end
```





Although the `Enumerated Constant` block outputs `True`, both `On` and `True` have the same underlying integer, and `On` is defined first in the class definition `enumeration`

section. Therefore, the `Display` block shows `On`. Similarly, a `Scope` axis would show only `On`, never `True`, no matter which of the two values is input to the `Scope` block.

Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter *`ClassName.EnumName`* in the MATLAB Command Window. The instance is created in the base workspace. For example, if `BasicColors` is defined as in "Create Simulink Enumeration Class" on page 58-8, you can type:

```
bcy = BasicColors.Yellow

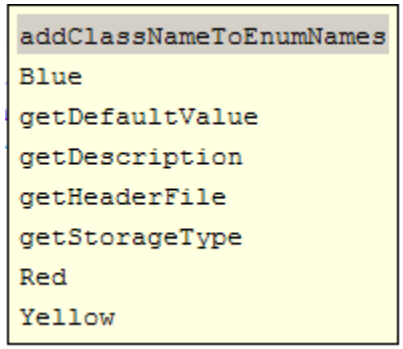
bcy =

    Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of `BasicColors` in alphabetical order:



Double-click an element or method to insert it at the position where you pressed `<tab>`. See "Tab Completion" for more information.

Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)

bcb =

    Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)

bci =

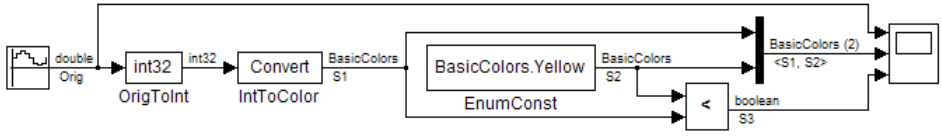
    2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

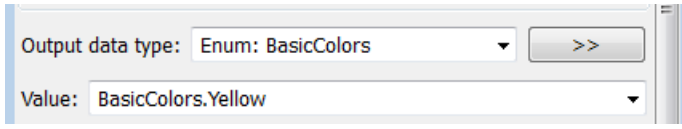
Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *`ClassName.EnumName`* as a value in a dialog box. For example, consider the following model:



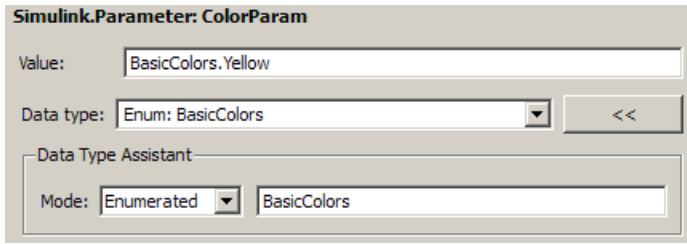
The `Enumerated Constant` block **EnumConst**, which outputs the enumerated value `Yellow`, defines that value as follows:



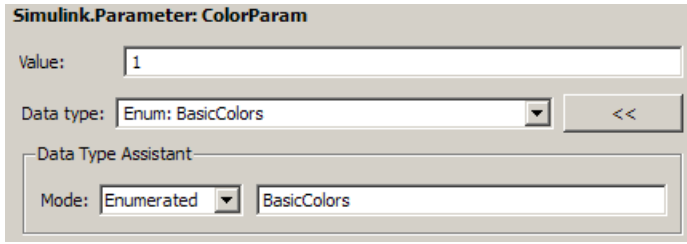
You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as`[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a `Constant` block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or ? prefix, as explained in "Specify Enumerations as Data Types" on page 58-16.



You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See "Enumerated Values in Computation" on page 58-22 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is `1`.



The same syntax and considerations apply in Stateflow. See "Enumerated Data" for more information.

Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of the enumerated signal values) and input the resulting integer signal to a Gain block. See "Casting Enumerated Signals" on page 58-22 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

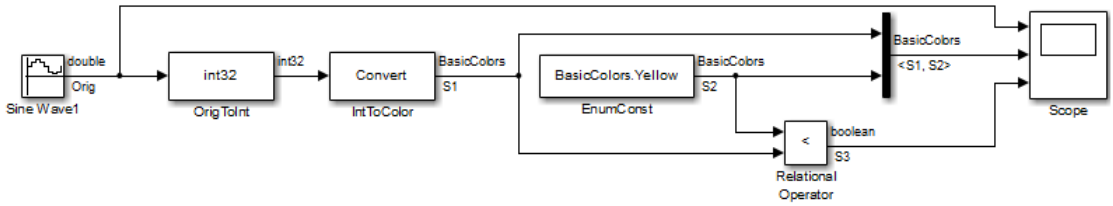
Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in "Simulate with

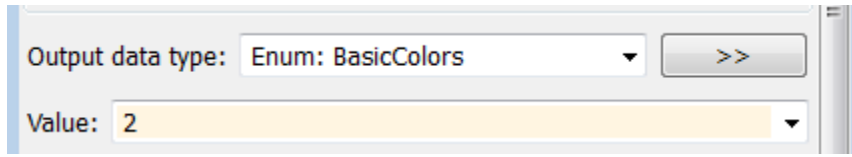
Enumerations" on page 58-14 needed two Data Conversion blocks to convert a sine wave to enumerated values.



The first block casts `double` to `int32`, and the second block casts `int32` to `BasicColors`. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

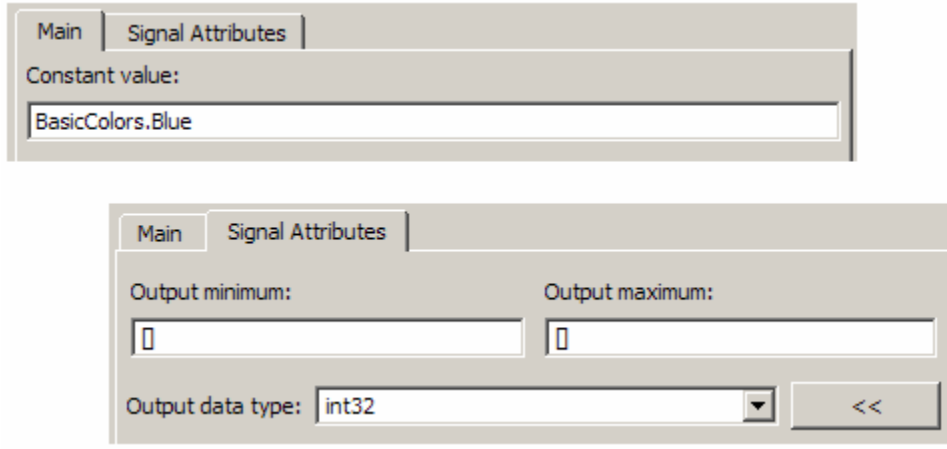
Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an `Enumerated Constant` block specifies a **Value** of `2` and an **Output data type** of `Enum: BasicColors`:



An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a `Constant` block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.



An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

Export Simulation Data

In this section...
"Simulation Data" on page 59-3
"Approaches for Exporting Signal Data" on page 59-4
"Enable Simulation Data Export" on page 59-6
"View Logged Data Using Simulation Data Inspector" on page 59-7
"Memory Performance" on page 59-7

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as "data logging" or "saving simulation data."

You can have data logged in different formats:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Note: The `ModelDataLogs` class is supported for backwards compatibility. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format. In R2016a or later, when you open a model from an earlier release that had used `ModelDataLogs` format, the model simulated in use `Dataset` format.

Consider converting this data to the `Dataset` format, which can simplify the post-processing of data. For more information, see “Dataset Conversion for Logged Data” on page 59-20.

You can also import the exported data to use as input for simulating a model.

Approaches for Exporting Signal Data

Exporting simulation data often involves exporting signal data. You can use various approaches for exporting signal data.

Export Approach	Usage	Documentation
Connect a Scope block or viewer to a signal.	If you use a Scope block for viewing results during simulation, consider also using the Scope block to export data. Save output at a sample rate other than the base sample rate. Scopes store data and can be memory intensive.	`Scope`
Connect a signal to a To File block.	Consider using a To File block for exporting large amounts of data. Save output at a sample rate other than the base sample rate. Use the MAT-file only after the simulation has completed.	`To File`
Connect a signal to a To Workspace block.	Document in the diagram the workspace variables used to store signal data. Save output at a sample rate other than the base sample rate.	`To Workspace`

Export Approach	Usage	Documentation
Connect a signal to a root-level Outport block.	Consider using this approach for logging data in a top-level model, if the model already includes an Outport block.	`Outport`
Set the signal logging properties for a signal.	Use signal logging to avoid adding blocks. Log signals based on individual signal rates. Data is available only when simulation is paused or completed. Use signal logging to log array of buses signals.	"Export Signal Data Using Signal Logging" on page 59-56
Configure Simulink to export time, state, and output data.	To capture complete information about the simulation as a whole, consider exporting this data. Outputs and states are logged at the base sample rate of the model.	"Data Format for Logged Simulation Data" on page 59-14 "Limit Amount of Exported Data" on page 59-39 "Samples to Export for Variable-Step Solvers" on page 59-52
Log a data store.	Log a data store to share data throughout a model hierarchy, capturing the order of all data store writes.	"Log Data Stores" on page 60-38

Export Approach	Usage	Documentation
Use the `sim` command to log simulation data programmatically.	Use `sim` to export to one data object the time, states, and signal simulation data. Select the **Return as single object** parameter when simulating the model using the `sim` command inside a function or a `parfor` loop.	`sim`

Enable Simulation Data Export

To export the states and root-level output ports of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Parameters** > **Data Import/Export** pane (for details, see "Data Import/Export Pane")
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
  - Signal logging
  - Time
  - Output
  - State or final state
  - Data store

  Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.
- The characteristics of the logged data, including:
  - "Data Format for Logged Simulation Data" on page 59-14
  - "Limit Data Logged" on page 59-63
  - "Samples to Export for Variable-Step Solvers" on page 59-52

View Logged Data Using Simulation Data Inspector

To inspect exported simulation data interactively, consider using the "Customize the Simulation Data Inspector Interface" on page 26-46.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See "Limitations of the Simulation Data Inspector" on page 26-60.

Memory Performance

Optimization for Logged Data

When exporting simulation data in a simulation mode other than Rapid Accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first timestamp, the length of the interval (time step), and the total number of timestamps.
- When multiple signals use identical sequences of timestamps, the signals share a single stored timestamp sequence. Sharing a single stored timestamp can reduce memory use for logged data by as much as a factor of two. An example when this memory performance can be a critical performance factor is when logging bus signals that have thousands of bus elements.

Logging to Persistent Storage

You can encounter memory issues when you log a large number of signals in a long simulation that has many time steps. Logging to persistent storage can address this kind of memory issue.

To log to persistent storage, in the **Configuration Parameters > Data Import/Export** pane, select **Log Dataset data to file** option. Specify the kinds of logging (for example, signal logging and states logging).

- For logging output and states data, set the **Format** parameter to `Dataset`.
- If you select the **Final states** parameter, clear the **Save complete SimState in final state** parameter.

Using a `Simulink.SimlationData.DatasetRef` object to access signal logging and states logging data loads data into the model workspace incrementally. Accessing data for other kinds of logging loads all of the data at once.

For details, see “Log Data Using Persistent Storage” on page 59-42.

Signal Data Storage for Loading

In this section...
“MATLAB Workspace for Signal Data” on page 59-9
“Source and Signal Builder Blocks for Signal Data” on page 59-10
“MAT-Files for Signal Data” on page 59-11
“Spreadsheets for Signal Data” on page 59-11

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

MATLAB Workspace for Signal Data

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

Create Signal Data in the MATLAB Workspace

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.
- Use the `csvread` function to read data from a CSV spreadsheet into the MATLAB workspace.

- Use a model callback to load signal data.
- Use one of these Simulink logging techniques:
  - Signal logging
  - To Workspace block
  - Scope block
  - The **Configuration Parameters** > **Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters.
  - Data store
  - The `sim` command configured to log simulation data

Load Signal Data from the MATLAB Workspace

To load signal data from a workspace, use one of these techniques:

- Add a From Workspace block.
- Use a root-level input port.
  - Specify workspace variables in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.
  - Use the Root Inport Mapping tool to specify the data for the **Input** parameter.

Source and Signal Builder Blocks for Signal Data

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define signal groups to use as inputs to a model, you can use the Signal Builder block. The Signal Builder block stores the signal group definitions.

Consider using a source block to:

- Avoid having to create the data manually.
- Reduce memory consumption — source blocks do not store signal data.
- Graphically represent in the model the kind of signal data.

Consider using a Signal Builder block to:

- Create and import signal groups for use in testing.

  You can use signal groups with Simulink and with these products:

  - Simulink Test
  - Simulink Verification and Validation
- Switch between signal groups quickly.

MAT-Files for Signal Data

Consider storing signal data in a MAT-file to:

- Load a large amount of signal data efficiently.
- Reuse the same signal data in different models.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.

Store Signal Data in a MAT-File

To create a MAT-file to store signal data to import, you can use:

- A To File block
- The Root Inport Mapping tool. Export to a MAT-file the signal data that you work on with the tool.
- MATLAB to create signal data that you store in a MAT-file
- `Simulink.saveVars` function to save to a MAT-file the simulation signal data that Simulink stores as workspace variables

Load Signal Data from a MAT-File

To load signal data from a MAT-file into a model, you can use a From File block.

Spreadsheets for Signal Data

Consider using an Excel or CSV spreadsheet to:

- Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.

- Load a large amount of signal data efficiently.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.
- Share the signal data with other people who do not have Simulink installed.

Store Signal Data in a Spreadsheet

Uuse one of these approaches:

- Create the signal data directly in the spreadsheet. For spreadsheet requirements, see "Storage Formats" on page 59-135.
- Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

Load Signal Data from a Spreadsheet

Use one of these blocks:

- From Spreadsheet block
- Signal Builder block

The From Spreadsheet and Signal Builder blocks load Microsoft Excel on all platforms. These blocks load CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet incrementally loads the data directly from the spreadsheet, to minimize memory consumption. The Signal Builder block imports all the spreadsheet data into MATLAB memory at one time and saves the data in the block.

Data Format for Logged Simulation Data

In this section...
"Data Format for Block-Based Logged Data" on page 59-14
"Data Format for Model-Based Logged Data" on page 59-14
"Logged Data Store Format" on page 59-14
"Time, State, and Output Data Format" on page 59-14

Data Format for Block-Based Logged Data

You can use the `Scope`, `To File`, or `To Workspace` blocks to export simulation data. Each of these blocks has a data format parameter.

Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- "Logged Data Store Format" on page 59-14
- "Time, State, and Output Data Format" on page 59-14

Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see "Accessing Data Store Logging Data" on page 60-40.

Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- "Dataset" on page 59-15 (default)

- "Array" on page 59-15
- "Structure with Time" on page 59-16
- "Structure" on page 59-18

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see "Export Signal Data Using Signal Logging" on page 59-56.

  1. In the Simulink Editor, select one or more signals.
  2. Click the **Simulation Data Inspector** button arrow and click **Log Selected Signals to Workspace**.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see "State Information" on page 59-220.

Dataset

`Dataset` format:

- Uses MATLAB timeseries objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
- Supports inclusion of units information in logged data for output data
- Does not support logging nonvirtual bus data for code generation or in rapid accelerator mode.

Array

If you select this `Array` option, Simulink saves the states and outputs of a model in a state and output array, respectively.

The state matrix has the name specified in the **Configuration Parameters** > **Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters** > **Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

Note: Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

- Data is all scalars or all vectors (or all matrices for states)
- Data is all real or all complex
- Data all has the same data type

If your model outputs and states do not meet these conditions, use the `Structure` or `Structure with time` output formats (see "Structure with Time" on page 59-16).

Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters** > **Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- `time`

  Contains a vector of the simulation times.

- `signals`

  Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- `values`

  Contains the outputs for the corresponding output port.

  - If outputs are scalars or vectors — `values` field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
  - If the outputs are matrix (2-D) values — `values` field is a 3-D array of dimensions `M-by-N-by-T`. `M-by-N` is the dimensions of the output signal and `T` is the number of output samples.
  - If `T = 1` — MATLAB drops the last dimension. Therefore, the `values` field is an `M-by-N` matrix.

- `dimensions`

  Specifies the dimensions of the output signal.

- `label`

  Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is `DSTATE` or `CSTATE`, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of `DSTATE`).

- `blockName`

  Specifies the name of the corresponding output port or block with states.

- `inReferencedModel`

  If the `signals` field records the final state of a block that resides in the reference model, contains a value of `1`. Otherwise, the value is false (`0`).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)
```

```
ans =

              values: [296206x1 double]
          dimensions: 1
               label: 'CSTATE'
           blockName: 'vdp/x1'
    inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- `time`

  The `time` field contains a vector of the simulation times.

- `signals`

  """The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each `signals` structure has four fields: `values`, `dimensions`, `label`, and `blockName`. The `values` field contains time samples of a state of the block specified by the `blockName` field. The `label` field for built-in blocks indicates the type of state: either `CSTATE` (continuous state) or `DSTATE` (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the `values` field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the `values` array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The `values` field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

Note: Simulink can read back simulation data saved to the MATLAB workspace in the `Structure with time` output format. See "Examples of Specifying Signal and Time Data" on page 59-217 for more information.

Structure

This format is the same as for `Structure with time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

Dataset Conversion for Logged Data

In this section...
"Why Convert to Dataset Format?" on page 59-20
"Results of Conversion" on page 59-21
"Dataset Conversion Limitations" on page 59-23

Why Convert to Dataset Format?

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB times eries
- `ModelDataLogs`

Converting data from other Simulink logging formats to `Dataset` format simplifies writing scripts to post-process data logged. For example, a model with multiple `To Workspace` blocks can use different data formats. Converting the logged data to `Dataset` format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB timeseries objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the logged data, you can use MATLAB time-series methods such as `filter`, `detrend`, and `resample`.

- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as its name. You can use a Name-Value pair to specify a `Dataset` name.

You can use the Simulink.SimulationData.DataSet.concat method to combine `Dataset` objects into one concatenated `Dataset` object.

Results of Conversion

`Dataset` objects hold data as elements. To display the elements of a `Dataset` variable, enter the variable name at the MATLAB command prompt. The elements of `Dataset` objects are different types, depending on the data they store. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements and state logging in `Dataset` format stores data as `Simulink.SimulationData.State` elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

Format	Conversion Result Notes
MATLAB time series	If you log nonbus data, during conversion, the software first adds the data as a `Simulink.SimulationData.Signal` object. It then adds that object as an element of the newly created `Dataset`. If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a `Simulink.SimulationData.Signal` object. It then adds that object as an element of the data set. Time-series objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.

Format	Conversion Result Notes
Structure and structure with time	Structure and structure with time formats do not always contain as much information as if you log in `Dataset` format. However, before converting structure and structure with time formats, the data structure must have `time` and `signals` fields. Conversion populates a `Simulink.SimulationData.Signal` object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called `blockName`, converting adds it to the block path. Otherwise, the block path is empty. When scope data is logged in structure format, the logged structure has a `PlotStyle` field. The software uses this field to set the interpolation in the `Dataset` object.
Array	Arrays contain little information. For example, there is no block path information. Conversion adds the array to a `Simulink.SimulationData.Signal` object and adds it as an element of the `Dataset` object. The conversion leaves unavailable information such as block path and timestamp fields as either empty or with default values.
`ModelDataLogs`	Converts data from `ModelDataLogs` format to `Dataset` format. **Note:** The `ModelDataLogs` format is no longer used for signal logging.

Dataset Conversion Limitations

- Converting logged data to `Dataset` format results in a `Dataset` object that contains all the information that the original logged data included. However, if there is no corresponding information for the other `Dataset` properties, the conversion uses default values for that information.
- To log variable-size signals, use the `To Workspace` block. If you convert data logged with To Workspace to be `Dataset` format, you lose the information about the variable-size signals.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:

  - The first column containing the data for the first signal in the bus
  - The second column containing data for the second bus signal, and so on

  When you convert that data to `Dataset`, the `Dataset` preserves that organization. But if you log the bus signal in `Dataset` format without conversion, the conversion captures the bus data as a structure of time-series objects.
- If the logged data does not include a time vector, when you convert that data to `Dataset`, the conversion inserts a time vector. There is one time step for each data value. However, the simulation time steps and the `Dataset` time steps can vary.
- `Dataset` format ignores the specification of frame signals. Conversion of structure or structure with time data to `Dataset` reshapes the data for logged frame signals.

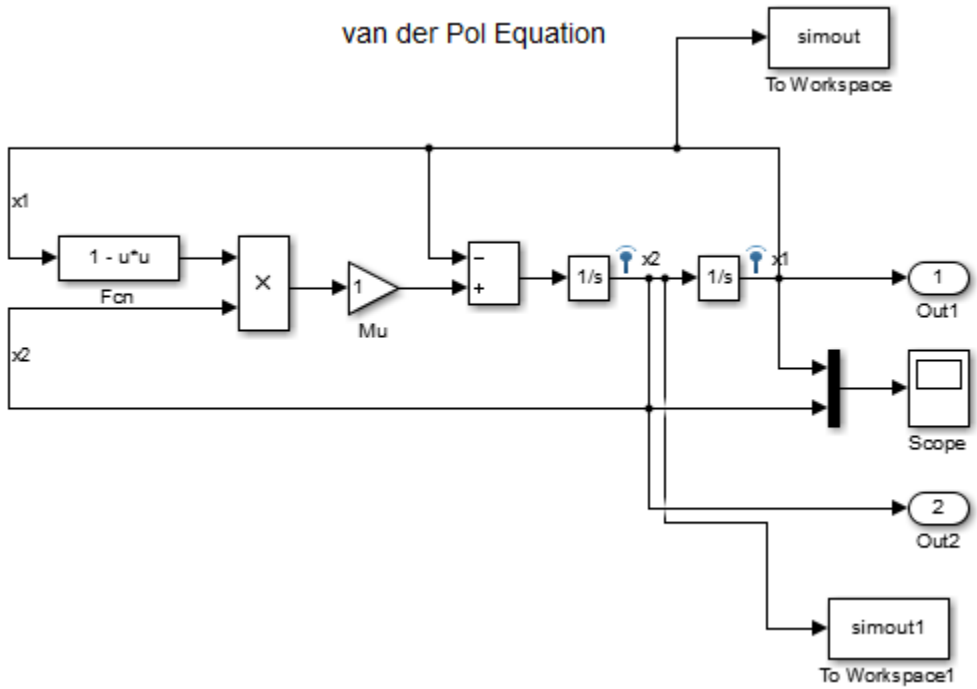
Convert Logged Data to Dataset Format

In this section...
“Convert Workspace Data to Dataset” on page 59-24
“Convert Structure Without Time to Dataset” on page 59-26
“Programmatically Access Logged Dataset Format Data” on page 59-30

Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to `Dataset` format. `myvdp_timeseries` is the `vdp` model with two `To Workspace` blocks configured for simout and simout1 logging data in MATLAB time-series format. Consider using a procedure like this one if you have models that use `To Workspace` blocks to log data to MATLAB time-series format.



Use the Simulink.SimulationData.Dataset constructor to convert the MATLAB time-series data to `Dataset` format and then concatenate the two data sets.

1. Starting with the `vdp` model, add two `To Workspace` blocks to the model as shown.
2. Set the **Save format** parameter of both blocks. Set `Timeseries`.
3. Save the model as `myvdp_timeseries`.
4. Simulate the model.

   The simulation logs data using the To Workspace blocks.
5. Access the signal logging format, `logsout`.

   ```
   logsout
   ```

   ```
   logsout =

     Simulink.SimulationData.Dataset
     Package: Simulink.SimulationData

     Characteristics:
                 Name: 'logsout'
       Total Elements: 2

     Elements:
       1: 'x1'
       2: 'x2'

     -Use get or getElement to access elements by index or name.
     -Use addElement or setElement to add or modify elements.

     Methods, Superclasses
   ```
6. Convert the MATLAB time-series data from both To Workspace blocks to `Dataset`.

   ```
   ds = Simulink.SimulationData.Dataset(simout);
   ds1 = Simulink.SimulationData.Dataset(simout1);
   ```

   ds is the variable name of the first To Workspace block data. *ds1* is the variable name of the second To Workspace block data.
7. Concatenate both datasets into *dsfinal*. Observe that the format of *dsfinal* matches that of `logsout`.

   ```
   dsfinal = ds.concat(ds1)
   ```

```
dsfinal =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'simout'
    Total Elements: 2

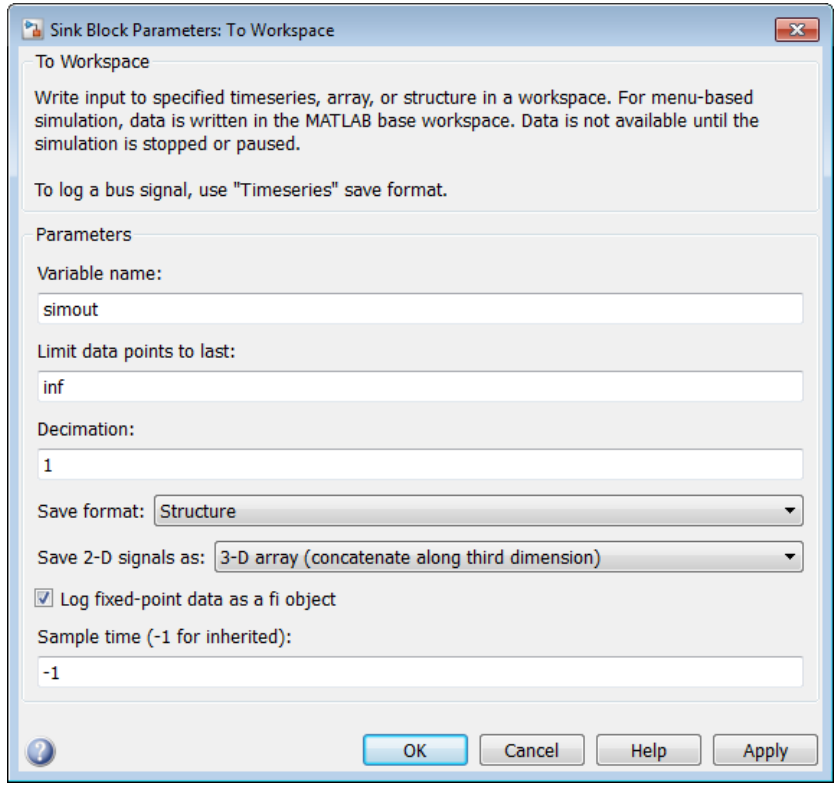
  Elements:
    1: 'x1'
    2: 'x2'

  -Use get or getElement to access elements by index or name.
  -Use addElement or setElement to add or modify elements.

  Methods, Superclasses
```

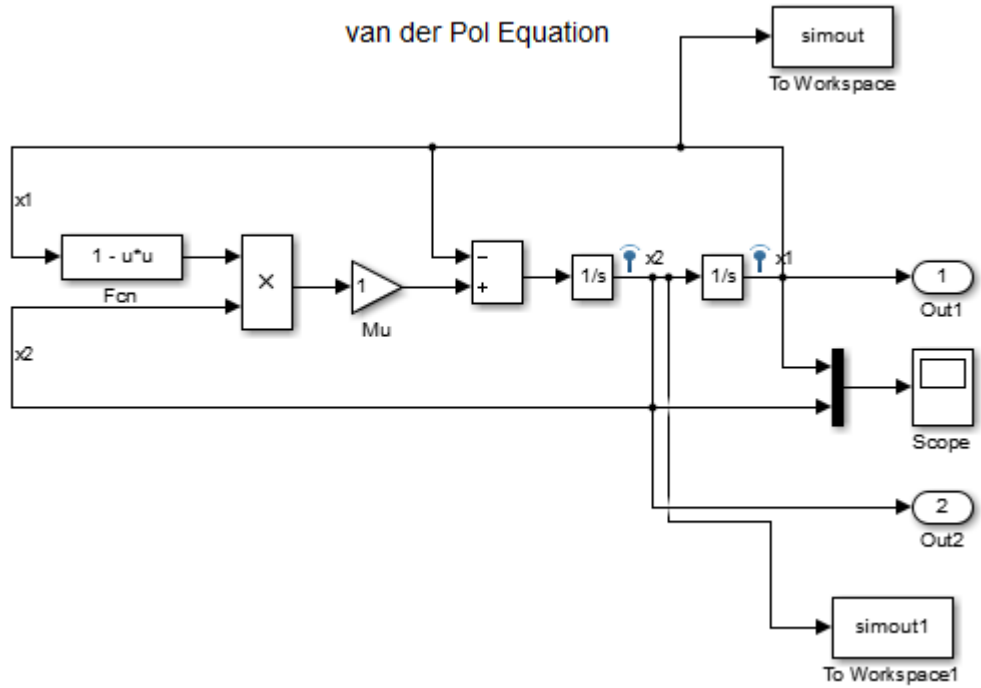
Convert Structure Without Time to Dataset

This example shows how to convert structure without time data to `Dataset` format. `myvdp_structure` is the `vdp` model with two `To Workspace` blocks configured for simout and simout1 logging data in structure format, as shown.



If you have models that use `To Workspace` blocks to log data to structure format, consider using a procedure like this one to convert them to `Dataset` format.

1 Starting with the `vdp` model, add two `To Workspace` blocks to the model as shown.



2. In the **Save format** parameter of both blocks, select `Structure`.
3. Enable signal logging for the two signals going to the two `To Workspace` blocks to log in `Ds` format.
4. Save the model as `myvdp_structure`.
5. Simulate the model.

   The simulation logs data using the To Workspace blocks.
6. Convert the structure data from both To Workspace blocks to `Dataset`.

   ```
   ds = Simulink.SimulationData.Dataset(simout);
   ds1 = Simulink.SimulationData.Dataset(simout1);
   ```

   simout is the variable name of the first To Workspace block data. *simout1* is the variable name of the second To Workspace block data.

With the conversion of structure without time or an array, time starts at t=0 and increments by 1.

7 Get the values of the first element in *ds*.

```
ds.get(1).Values.Time
```

```
ans =

     0
     1
     2
     3
     .
     .
     .
    61
    62
    63
```

8 Get the time values of the first element from signal logging.

```
logsout.get(1).Values.Time
```

```
ans =

         0
    0.0001
    0.0006
    0.0031
     .
     .
     .
   19.2802
   19.6802
   20.0000
```

9 Observe the discrepancy in timestamps between

- Data logged in structure without time that you convert to `Dataset` format
- Data logged in `Dataset` format

Programmatically Access Logged Dataset Format Data

When you use the default `Dataset` signal logging format, Simulink saves the logging data in a `Simulink.SimulationData.Dataset` object. For information about extracting signal data from that object, see the `Simulink.SimulationData.Dataset` reference page.

The `Simulink.SimulationData.Dataset` object contains a `Simulink.SimulationData.Signal` object for each logged signal.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB `timeseries` objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

Name	Description
`Simulink.SimulationData.DataSet.ge` You can also use the `getElement` method, which shares syntax and behavior as the `get` method.	Get element or collection of elements from the dataset, based on index, name, or block path.
`Simulink.SimulationData.DataSet.nu`	Get number of elements in the dataset.

For example of accessing signal logging data that uses the `Dataset` format, see `Simulink.SimulationData.Dataset`.

Access Array of Buses Signal Logging Data

Signal logging data for an array of buses uses `Dataset` signal logging format.

The general approach to access data for a specific signal in an array of buses is:

1. Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logsout` variable).
2. To get the values, index within the array of buses.
3. Index again to get data for a specific bus.

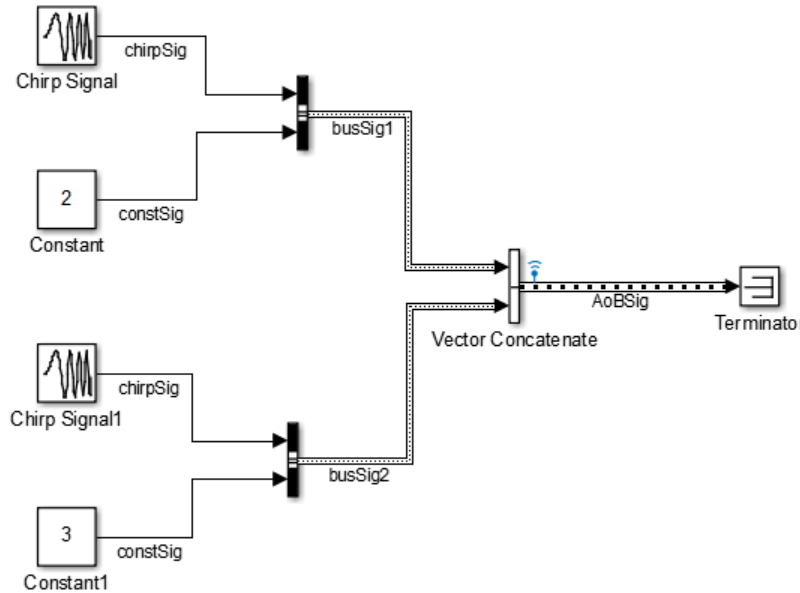
For example, to obtain the signal logging data for the Constant6 block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the Terminator block:

```
logsout.getElement('topBus').Values.a(2,2).firstConst.data
```

Here are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_mdlref_bus`.

Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).



To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

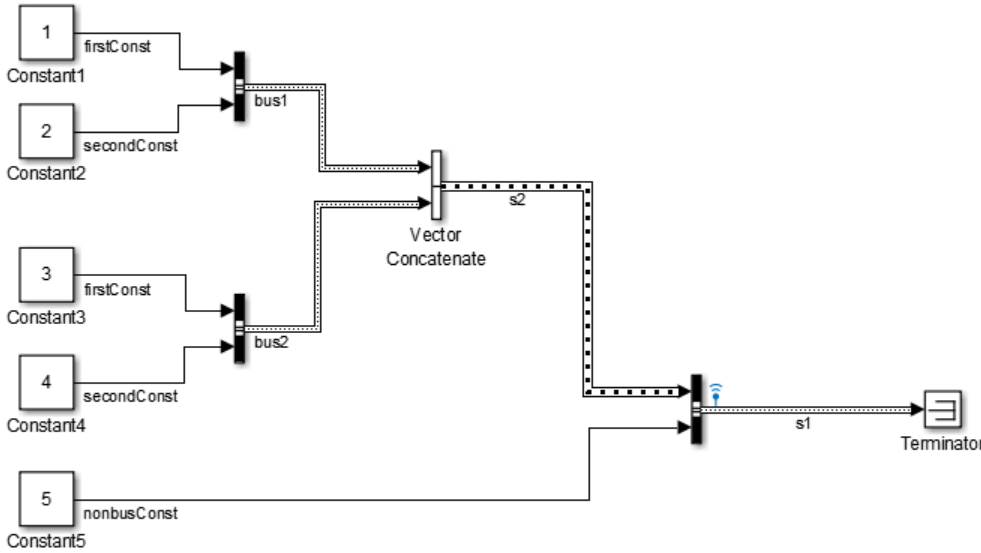
```
logsout.getElement('AoBSig').Values(2).chirpSig.Data
```

```
ans=

    0
  0.9585
```

Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (`s2`) that feeds into bus `s1`.



This example shows navigation to the `Constant3` block, which is a signal in `bus2`.

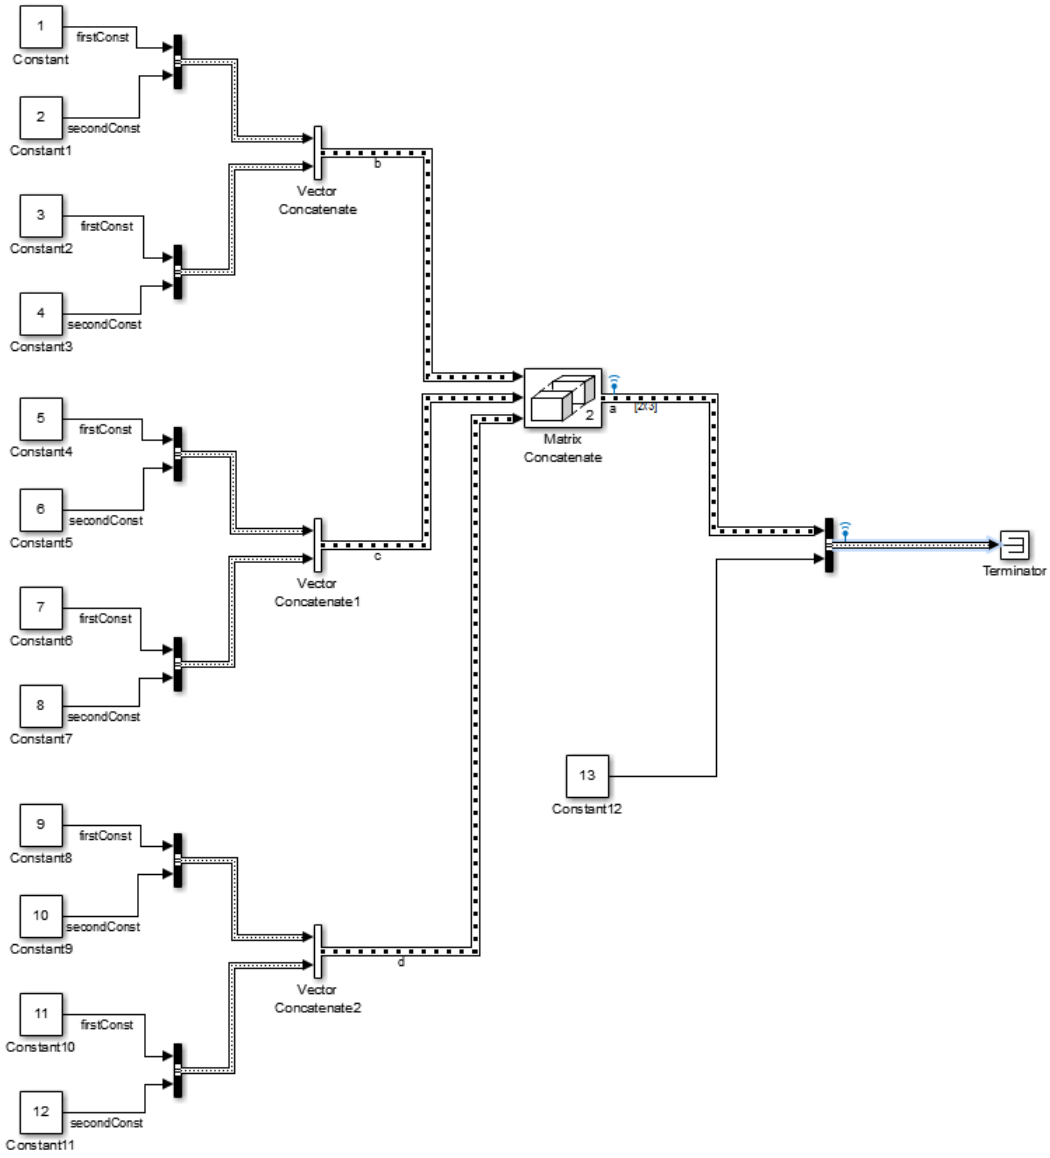
```
logsout.getElement('s1').Values.s2(2).firstConst.Data
```

```
ans=

   3
   3
   3
   3
   3
   3
   3
```

Nested Arrays of Buses

The `ex_log_nested_aob` model has an array of buses (`a`) that is made up of three arrays of buses: `b`, `c`, and `d`. The Matrix Concatenate block combines the nested arrays of buses into array of buses `a`.



This example shows navigation to the `Constant6` block.

```
logsout.getElement('topBus').Values.a(2,2).firstConst.Data

ans=

  7
  7
  7
  7
  7
  7
  7
  7
  7
  7
  7
```

Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, signal logging data includes a `Simulink.SimulationData.Signal` object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use *one* of these approaches:

- To find the data for the specific signal, visually inspect the displayed output of `Simulink.SimulationData.Signal` objects.
- Use the `Simulink.SimulationData.Dataset.getElement` method, specifying the blockpath for the source block of the signal.
- To iterate through the signals with a duplicate signal name, create a script using the `Simulink.SimulationData.Dataset.getElement` method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in normal mode.

  1. In the model, right-click the signal.
  2. In the context menu, select **Properties**.
  3. In the Signal Properties dialog box, set **Logging name** to `Custom` and specify a different name than the signal name.

4 Simulate the model and use the `Simulink.SimulationData.Dataset.getElement` method with a name argument.

Tip Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see "Override Signal Logging Settings with the Signal Logging Selector" on page 59-79.

Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses `Dataset` format, use a `sprintf` command within a `getElement` call. For example:

```
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

Log Signal Data That Uses Units

To have logged data include the units specified for signals, use the `Dataset` or `Timeseries` logging format, which stores logging information in MATLAB `timeseries` objects.

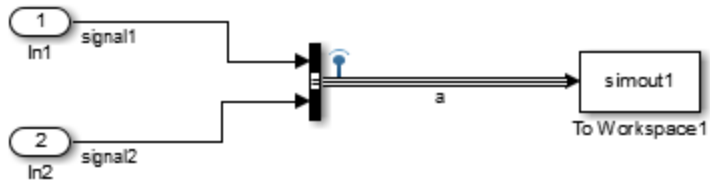
Signal logging uses `Dataset` format. Output logging (**Configuration Parameters** > **Data Import/Export** > **Output**) uses `Dataset` as the default format. The default save format for the To File and To Workspace blocks is `Timeseries`.

If you use `Dataset` or `Timeseries` format for signal logging or for To File block or To Workspace block logging, the logged data includes units information.

To capture units information for output logging:

1. Set the **Configuration Parameters** > **All Parameters** > **Format** parameter to `Dataset`.
2. In the Block Parameters dialog box for Outport blocks for which you want to capture units information, set the **Unit** parameter to match the units of the input signal.

For example, in this model the In1 block has its **Unit** parameter set to `newton` and In2 block uses `m` (meters). Open the model. After you simulate the model, you can see the units for the logged data.



- You can view the units in the signal logging data for `signal1` of the bus signal `b`.

```
logsout.get('a').Values.signal1.DataInfo
```

```
tsdata.datametadata
  Package: tsdata

  Common Properties:
              Units: newton (Simulink.SimulationData.Unit)
```

```
        Interpolation: linear (tsdata.interpolation)
```

- You can view the units in the data logged in the To Workspace block.

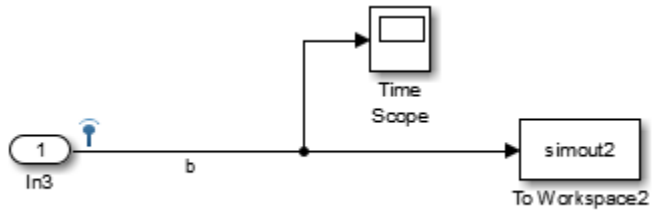
```
simout1.signal2.DataInfo.Units

ans =

  Units with properties:

    Name: 'm'
```

This example model shows how to view the data logged in a Time Scope block. Open the model.



To use the Time Scope block to log data, in the scope select **Configuration Properties > Logging > Log data to workspace** and specify a variable (`ScopeData` in this example). The `In3` block uses `m` (meters). Simulate the model and then at the MATLAB command line, enter:

```
ScopeData.get(1).Values.DataInfo.Units

ans =

  Units with properties:

    Name: 'm'
```

Limit Amount of Exported Data

In this section...
"Decimation" on page 59-39 "Limit Data Points" on page 59-40 "Logging Intervals" on page 59-40

You can use several options to reduce the amount of data logged during a simulation. Limiting the amount of exported simulation data reduces memory usage and speeds up simulation. You can use multiple techniques for the same simulation.

Technique	Description
Specify a decimation factor	Skip samples when exporting data.
Limit data points	Limit the number of samples saved to be only the most recent samples
Specify an interval for logging	Specify ranges of time steps for logging

Alternatively, for logging large amounts of data that can cause memory issues, consider logging to persistent storage. This approach preserves all of the logging data, minimizing MATLAB workspace memory usage. For details, see "Log Data Using Persistent Storage" on page 59-42.

Decimation

To skip samples when exporting data, apply a decimation factor. For example, a decimation factor of 2 saves every other sample. By default, decimation is set to 1, which does not skip any samples.

The approach you use to specify a decimation factor depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the **Decimation** parameter.

Data	How to Specify
Data store logging	From the Block Parameters dialog box for that block, open the **Logging** tab. Apply a decimation factor using the **Decimation** parameter.
State and output	Enter a value in the field to the right of the **Decimation** label.

Limit Data Points

To limit the number of samples saved to be only the most recent samples, set the **Limit Data Points** parameter.

The approach you use depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the **Limit Data Points to Last** parameter.
Data store logging	From the Block Parameters dialog box for that block, open the **Logging** tab. Select the **Limit Data Points to Last** parameter.
Time, state, and output logging	Select the **Configuration Parameters > All Parameters > Limit data points** parameter and for the **Configuration Parameters > All Parameters > Maximum number of data points** parameter, specify the limit.

Logging Intervals

To specify an interval for logging, use the **Configuration Parameters > Data Import/ Export > Logging intervals** parameter. Limiting logging to a specified interval allows you to examine specific logged data without changing the model or adding complexity to a model.

The logging intervals apply to data logged for:

- Time
- States
- Output
- Signal logging
- The To Workspace block
- The To File block

The logging intervals do not apply to final state logged data, scopes, or streaming data to the Simulation Data Inspector.

The intervals specified with **Logging intervals** establish the set of times to which the **Decimation** and **Limit data points to last** parameters apply. For example, suppose that you set the logging interval `[2,4;7,9]` with a fixed-step solver with a fixed-step size of 1. The logged times are 2, 3, 4, 7, 8, and 9.

Log Data Using Persistent Storage

In this section...
"When to Use Persistent Storage" on page 59-42
"General Workflow for Logging to Persistent Storage" on page 59-44
"Supported Logging Techniques" on page 59-44
"Use Dataset Format for Logging" on page 59-44
"Enable Logging to Persistent Storage" on page 59-45
"Programmatic Interface for Logging to Persistent Storage" on page 59-45
"How Simulation Data is Stored" on page 59-45
"Save Logged Data from Successive Simulations" on page 59-46

You can store logged simulation data to persistent storage in a MAT-file. Using persistent storage minimizes the amount of logged data stored in memory during simulation.

You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter, without changing the model layout.

To access the logged data from the file, you can either create reference objects in the MATLAB workspace or load the entire data at once. A reference object identifies the file and the logging variable (for example, `logsout` for signal logging data) for the logged data that you want to access. When you access signal logging and state logging data, Simulink loads that data into the workspace incrementally.

When to Use Persistent Storage

You can encounter memory issues when you log a large number of signals in a long simulation that has many time steps. Logging to persistent storage can address these kinds of memory issues. Persistent storage is also useful for logging when you run simulations in parallel.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For many models, logging to the workspace is simpler because it avoids loading and saving logging files.

For very short simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

Limitations for Logging to Persistent Storage

- Only data logged in `Dataset` format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export > Save complete SimState in final state**.
- The Simulation Stepper and Fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model.

Alternative Approaches for Reducing Logging Memory Usage

If simulating a model that uses logging does cause memory issues, alternatives to logging to persistent storage include:

- Limit the amount of simulation data stored in the workspace.
- Use a To File block for each signal that you want to log.

You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Limit Amount of Exported Data” on page 59-39.

Technique	Description
Specify a decimation factor.	Skip samples when exporting data.
Limit data points.	Limit the number of samples saved to be only the most recent samples.
Specify intervals for logging.	Specify ranges of time steps for logging.

However, if you limit the amount of simulation data, the logged data can skip some time steps that are critical for testing and analyzing the model.

Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:

- Is a per-signal approach that can clutter a model with multiple `To File` blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, compared to the one MAT-file used by logging to persistent storage.

General Workflow for Logging to Persistent Storage

Use this workflow to log data to persistent storage and access that data. You can use the **Configuration Parameters > Data Import/Export** pane to configure a model to log to persistent storage.

1. Select the kinds of logging to perform (for example, signal logging and states logging) and specify the variables for the logging.
2. Use `Dataset` format for logging the data.
3. Enable logging to persistent storage and specify an outpout MAT-file name.
4. Simulate the model.
5. Get a list of the `Dataset` variables in the MAT-file.
6. Create a reference object for each kind of simulation data you want to access from the MAT-file.
7. Access the data.

Supported Logging Techniques

You log to persistent storage `Dataset` format data for these kinds of logging:

- Signal logging
- States
- Final states
- Output
- Data stores

Use Dataset Format for Logging

Logging to persistent storage stores `Dataset` format logging data in the MAT-file. Data that is logged in any other format is stored in the workspace.

Signal logging and data store logging use `Dataset` format. The default format for logged output, states, and final states is `Dataset`.

For final states logging, also clear the **Save complete SimState in final state** parameter.

Enable Logging to Persistent Storage

Select the **Log Dataset data to file** parameter. Specify the MAT-file to use. Do not use a file name from one locale in a different locale.

Programmatic Interface for Logging to Persistent Storage

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to `'on'`:

- `SignalLogging`
- `SaveState`
- `SaveFinalState`
- `SaveOutput`
- `DSMLogging`

- To log output, states, and final states data to persistent storage, set the `SaveFormat` parameter to `'Dataset'`.
- To log final states data to persistent storage, set the `SaveCompleteFinalSimState` to `'off'`.
-

How Simulation Data is Stored

Logging to persistent storage saves logged simulation data in the specified MAT-file a `Simulink.SimulationData.Dataset` object for the data for each kind of logging that uses `Dataset` format. The data set object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logsout`, then the data set object in the MAT-file is `logsout`.

Save Logged Data from Successive Simulations

Each time you simulate the model, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve the data in the file, it retrieves the most recent version of the data.

To preserve data from an earlier simulation, you can use one of these approaches:

- Between simulations, use the **Configuration Parameters** > **Data Import/Export** pane to specify a different name for MAT-file for logging.
- Between simulations, save a copy of the MAT-file, using a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.
- Programmatically specify a new file name for each simulation run.

If you change the file name used for logging to persistent storage, then to access the logged data, you need to either create new reference objects or change the `Location` property of the reference objects to match the new file name. For details about using reference objects to access logged data, see "Access Logged Data from Persistent Storage" on page 59-47.

Access Logged Data from Persistent Storage

In this section...

"Access Logged Signal Logging and States Data" on page 59-47
"Access Output and Data Store Data" on page 59-47
"Get List of Dataset Variables" on page 59-48
"Create References to Persistent Storage Dataset Objects" on page 59-48

You can access data logged to persistent storage for analysis in MATLAB. Data logged in a format other than `Dataset` format is stored in the MATLAB workspace.

Access Logged Signal Logging and States Data

To access logged data stored in MAT-file:

1. Create a `Simulink.SimulationData.DatasetRef` reference object for each kind of logged data you want to access. For example, to access signal logging data and states logging data in a MAT-file, create two reference objects.
2. Use these `Simulink.SimulationData.DatasetRef` methods to access the data:
   - `numElements`
   - `getElementNames`
   - `get` (or the alias `getElement`)

When you access signal logging or states logging data from a MAT-file, Simulink reads the data to the MATLAB workspace incrementally (signal by signal).

When you use a `Simulink.SimulationData.DatasetRef` object that references data in a MAT-file to retrieve the data in the file, it retrieves the most recent version of the data.

For an example of accessing data logged to persistent storage, see "Create References to Persistent Storage Dataset Objects" on page 59-48.

Access Output and Data Store Data

To access logged output and data store data, use the same approach as for accessing signal logging and states logging data (see "Access Logged Signal Logging and States Data" on page 59-47).

However, when you access output or data store logging information from a MAT-file, Simulink loads all of that data into the MATLAB workspace.

Get List of Dataset Variables

To create a reference to persistent storage `Dataset` objects in the MAT-file that stores the logged data, you need to know the names of the `Dataset` variables in the file. You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to get a list of the `Dataset` variables in a MAT-file.

Tip To get the names of `Dataset` variables in the MAT-file, using the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function processes faster than using the `who` or `whos` functions.

Create References to Persistent Storage Dataset Objects

This example shows how to construct and use `Simulink.SimulationData.DatasetRef` objects to access data for a model that logs to persistent storage. This simple example shows the basic steps for logging to persistent storage. This example does not represent a realistic situation for logging to persistent storage, because it shows a short simulation with small memory requirements.

1. Open the vdp model.
2. In the **Configuration Parameters** > **Data Import/Export** pane, select these parameters:

   - **States**
   - **Log Dataset data to file**

   Set the **Format** parameter to `Dataset`.

   Leave the other parameter settings as they are and click **Apply**.
3. In the model, right-click a signal and in the Signal Properties dialog box, select **Log signal data**.
4. Simulate the model.
5. Get a list of `Dataset` variable names in the `out.mat` file.

   ```
   varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('out.mat')
   ```

```
varNames =

    'xout'
    'logsout'
```

6 Create a reference to the logged states data that is stored in `out.mat`. The variable for the logged states data is `xout`.

```
statesLogRef = Simulink.SimulationData.DatasetRef('out.mat.','xout')

statesLogRef =

  Simulink.SimulationData.DatasetRef
  Package: Simulink.SimulationData

  Characteristics:
          Location: out.mat. (H:\out.mat)
        Identifier: xout

  Resolved Dataset:
              Name: 'xout'
    Total Elements: 2

  Elements:
    1 : ''
    2 : ''

  Methods, Superclasses
```

7 Create a reference to the signal logging data that is stored in `out.mat`. The variable for the signal logging data is `logsout`.

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat.','logsout')

sigLogRef =

  Simulink.SimulationData.DatasetRef
  Package: Simulink.SimulationData

  Characteristics:
          Location: out.mat. (H:\out.mat)
        Identifier: logsout

  Resolved Dataset:
              Name: 'logsout'
```

```
    Total Elements: 1

  Elements:
    1 : 'x1'

  Methods, Superclasses
```

8 Use the `DatasetRef` object to access the number of elements in the logged states data set.

```
statesLogRef.numElements

ans =

     2
```

9 Use the `DatasetRef` to access the first element of the signal logging data set.

```
sigLogRef.get(1)

ans =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
              Name: 'x1'
    PropagatedName: ''
         BlockPath: [1x1 Simulink.SimulationData.BlockPath]
          PortType: 'outport'
         PortIndex: 1
            Values: [1x1 timeseries]

  Methods, Superclasses
```

10 Delete the persistent storage MAT-file and try to use one of the `DatasetRef` objects.

```
delete('mat.out');
statesLogRef.get(1)

File does not exist.
```

The `statesLogRef` still exists, but it is a reference to a `Dataset` object that is in a file that no longer exists.

Samples to Export for Variable-Step Solvers

In this section...
"Output Options" on page 59-52
"Refine Output" on page 59-52
"Produce Additional Output" on page 59-53
"Produce Specified Output Only" on page 59-54

Output Options

Use the **Output options** list under **Configuration Parameters > Data Import/ Export > Additional parameters** to control how much output the simulation generates when your model uses a variable-step solver.

- `Refine factor` (default)
- `Produce additional output`
- `Produce specified output only`

Refine Output

The `Refine output` option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing `Refine output` and specifying a refine factor of 2 generates output at these times:

```
0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10
```

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes

the simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver can take large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` can provide much smoother results.

Note This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).

Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/ Export** pane displays an **Output times** parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing the `Produce additional output` option and specifying `[0:10]` generates output at these times:

```
0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
```

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).
- Set the **Output times** parameter to a value other than the default empty matrix (`[ ]`).
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing the `Produce specified output only` option and specifying `[1:9]` generates output at these times:

```
0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
```

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).
- Set the **Output times** parameter to a value other than the default empty matrix ([ ]).
- In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:
  - The times that you specify
  - All the time steps in between the values that you specify
  - The simulation start and stop times
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Export Signal Data Using Signal Logging

In this section...
“Signal Logging” on page 59-56
“Signal Logging Workflow” on page 59-56
“Signal Logging in Rapid Accelerator Mode” on page 59-57
“Signal Logging Limitations” on page 59-57

Signal Logging

To capture signal data from a simulation, usually you can use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 59-59 and “Enable Signal Logging for a Model” on page 59-74.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 59-3.

Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

1. Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 59-59.
2. Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 59-74.
3. Simulate the model.
4. Access the signal logging data. See “Access Signal Logging Data” on page 59-92.

Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging. Then select different subsets of signals to log by overriding signal logging settings. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 59-78.

Use this approach to log signals in models that use model referencing. See “Models with Model Referencing: Overriding Signal Logging Settings” on page 59-82.

Additional Signal Logging Options

With the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See "Specify Signal-Level Logging Name" on page 59-61.
- Control how much data the simulation generates for a signal. See "Limit Data Logged" on page 59-63.
- Review the signal logging configuration for a model. See "View the Signal Logging Configuration" on page 59-67.
- Specify the samples for export for models with variable-step solvers. See "Samples to Export for Variable-Step Solvers" on page 59-52.
- Configure the model to display signal logging data in the Simulation Data Inspector. See "View Data in Simulation Data Inspector" on page 59-92.

Signal Logging in Rapid Accelerator Mode

Signal logging in rapid accelerator mode does not log the following kinds of signals. When you update or simulate a model that contains these signals, Simulink displays a warning that those signals are not logged.

- Signals inside Stateflow charts
- Signals that use a custom data type

If you set the **Configuration Parameters > Solver > Sample time constraint** parameter to `Ensure sample time independent`, you cannot use signal logging in rapid accelerator mode.

Signal Logging Limitations

- Rapid accelerator mode supports signal logging, with the requirements and limitations described in "Signal Logging in Rapid Accelerator Mode" on page 59-57.
- Top-model and `Model` block software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulation modes support signal logging. For a description of limitations, see "Top-Model SIL/PIL Limitations" and "Model Block SIL/PIL Limitations" in the Embedded Coder documentation.

- Array of buses signals support signal logging, with the requirements described in "Import Array of Buses Data" on page 59-152.
- You cannot log signals in For Each subsystems.
- You cannot log local data in Stateflow Truth Table blocks.

More About

- "Export Simulation Data" on page 59-3

Configure a Signal for Logging

In this section...
"Mark a Signal for Signal Logging" on page 59-59
"Specify Signal-Level Logging Name" on page 59-61
"Limit Data Logged" on page 59-63
"Set Sample Time for a Logged Signal" on page 59-63

Mark a Signal for Signal Logging

Enable logging by marking a signal, using one of the following techniques:

- "Enable Signal Logging Using Simulink Editor Menu Options" on page 59-59
- "Enable Signal Logging Using Signal Properties" on page 59-60
- "Enable Signal Logging Using Model Explorer" on page 59-60
- "Programmatic Interface" on page 59-60

The Simulink Editor menu options generally are the simplest way to mark signals for signal logging.

A signal for which you enable signal logging is a *logged signal*. By default, Simulink displays a logged signal indicator for each logged signal.

Enable Signal Logging Using Simulink Editor Menu Options

1. In the Simulink Editor, select one or more signals.
2. Click the **Simulation Data Inspector** button arrow and click **Log Selected Signals to Workspace**.

Alternatively, you can select one or more signals and check **Simulation > Output > Log Selected Signals to Workspace**.

If you select multiple signals, the signal logging configuration that Simulink sets depends on whether any of the selected signals are marked for signal logging.

Signal Logging for Selected Signals	Result of Enabling the Log/Unlog Selected Signals Option
At least one of the selected signals does not have signal logging enabled.	Enables signal logging for all the selected signals
All selected signals have signal logging enabled.	Disables signal logging for all the selected signals

Enable Signal Logging Using Signal Properties

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. In the Signal Properties dialog box, in the **Logging and accessibility** tab, select **Log signal data**.
4. Click **OK**.

Enable Signal Logging Using Model Explorer

Note: The only signals that Model Explorer displays are named signals. See "Signal Names and Labels" on page 62-5.

1. In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to enable signal logging.
2. If the **Contents** pane does not display the `DataLogging` property, set the **Column view** to `Signals` or add the `DataLogging` property to the current view. For details about column views, see "Control Model Explorer Contents Using Views" on page 12-26.
3. Enable the `DataLogging` property for one or more signals.

However, the Model Explorer does not display unnamed signals. To display the `DataLogging` property (which sets up logging for a signal) can require that you reconfigure the Model Explorer.

Programmatic Interface

To enable signal logging programmatically for selected blocks, use the outport `DataLogging` property. Set this property using the `set_param` command. For example:

1. At the MATLAB Command Window, open a model. Type

```
vdp
```

2 Get the port handles of the signal that you want to log. For example, for the Mu block outport signal.

```
ph = get_param('vdp/Mu','PortHandles')
```

3 Enable signal logging for the desired outport signal.

```
set_param(ph.Outport(1),'DataLogging','on')
```

The logged signal indicator appears.

Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see "Models with Model Referencing: Overriding Signal Logging Settings" on page 59-82.

Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use *one* of the following approaches:

- "Signal-Level Logging Name in the Editor" on page 59-62
- "Signal-Level Logging Name in Model Explorer" on page 59-62
- "Signal-Specific Logging Name Specified Programmatically" on page 59-62

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink uses a blank name.

Note: The signal-level logging name is distinct from the model-level signal logging name. The model-level signal logging name is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `logsout`. For details about the model-level signal logging name, see "Specify a Name for Signal Logging Data" on page 59-77.

Signal-Level Logging Name in the Editor

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. Specify the logging name:
   a. In the Signal Properties dialog box, select the **Logging and accessibility** tab.
   b. From the **Logging name** list, select `Custom`.
   c. Enter the logging name in the adjacent text field.

Signal-Level Logging Name in Model Explorer

1. In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.
2. If the **Contents** pane does not display the `LoggingName` property, add the `LoggingName` property to the current view. For details about column views, see "Control Model Explorer Contents Using Views" on page 12-26.
3. Enter a logging name for one or more signals using the `LoggingName` column.

Signal-Specific Logging Name Specified Programmatically

Enable signal logging programmatically for selected blocks with the outport `DataLogging` property. Set this property using the `set_param` command.

1. At the MATLAB Command Window, open a model. For example, type:

   ```
   vdp
   ```

2. Get the port handles of the signal that you want to log. For example, for the Mu block outport signal:

   ```
   ph = get_param('vdp/Mu','PortHandles');
   ```

3. Enable signal logging for the desired outport signal:

   ```
   set_param(ph.Outport(1),'DataLogging','on');
   ```

   The logged signal indicator appears.

4. Issue commands that use the `DataLoggingNameMode` and `DataLoggingName` parameters. For example:

   ```
   set_param(ph.Outport(1),'DataLoggingNameMode','Custom');
   set_param(ph.Outport(1),'DataLoggingName','x2_log');
   ```

Limit Data Logged

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples

You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

Use Signal Properties to Limit Logged Data

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:
   - **Limit data points to last**
   - **Decimation**

Use Model Explorer to Limit Data Logged

1. In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.
2. If the **Contents** pane does not display the `DataLoggingDecimation` property or the `DataLoggingLimitDataPoints` property, add one or both of those properties to the current view. For details about column views, see "Control Model Explorer Contents Using Views" on page 12-26.
3. To specify a decimation factor, edit the `Decimation` and `DecimateData` properties. To limit the number of samples logged, edit the `LimitDataPoints` property.

Set Sample Time for a Logged Signal

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals

- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

Usage Notes

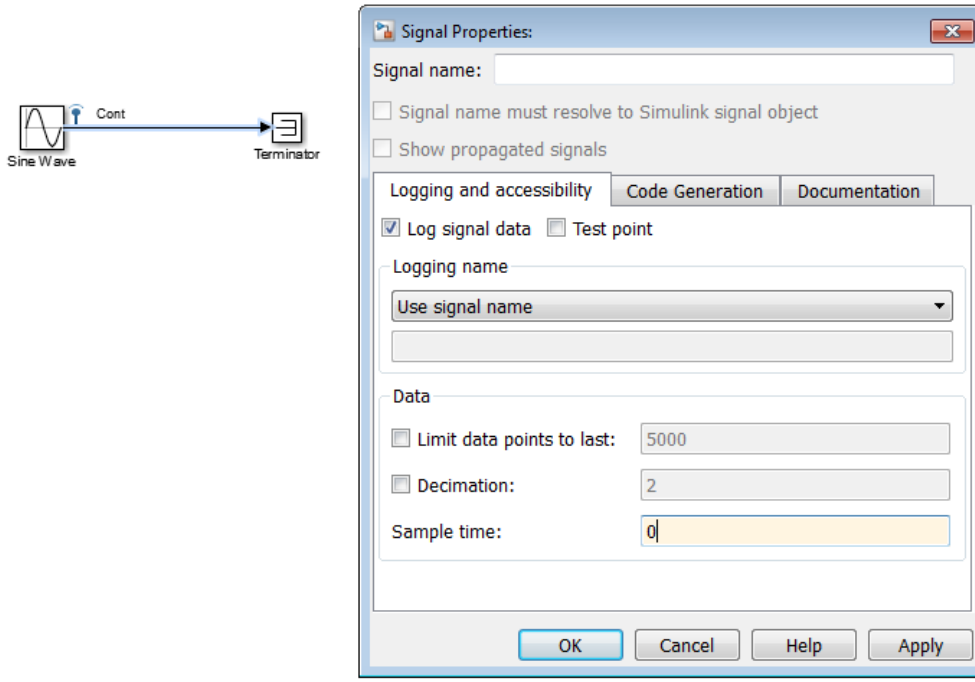
Do not specify a sample time for:

- Frame-based signals
- Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block and a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose that a model includes a continuous signal and the sample time is inherited (`-1`). The logged output for that signal shows that the interpolation method is `linear`.



```
logsout.get(1).Values.DataInfo
```

```
tsdata.datametadata
  Package: tsdata

  Common Properties:
              Units: ''
      Interpolation: linear (tsdata.interpolation)
```

If you change the sample time to be continuous (`0`), the logged output for that signal shows that the interpolation method is `zoh` (zero-order hold).

View the Signal Logging Configuration

In this section...
"Approaches for Viewing the Signal Logging Configuration" on page 59-67
"Use Simulink Editor to View Signal Logging Configuration" on page 59-68
"View Logging Configuration with Signal Logging Selector" on page 59-70
"Use Model Explorer to View Signal Logging Configuration" on page 59-72
"Programmatically Find Signals Configured for Logging" on page 59-73

Approaches for Viewing the Signal Logging Configuration

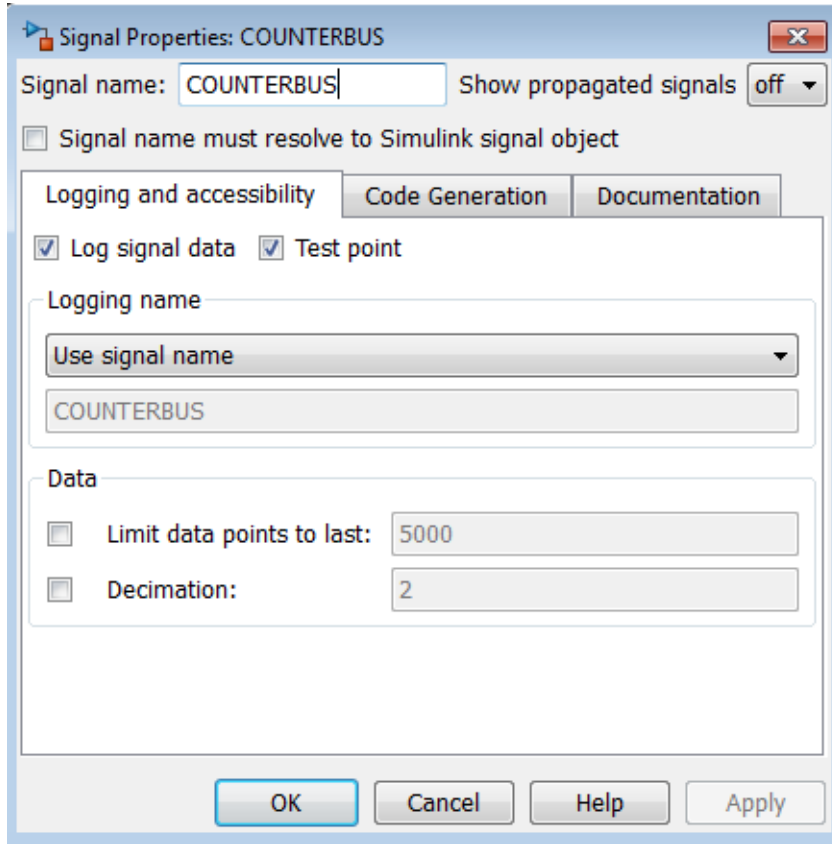
Signal Logging Configuration Viewing Approach	Usage	Documentation
In the Simulink Editor, view signal logging indicators.	Consider using this approach for models that have few signals marked for signal logging and have a shallow model hierarchy. This approach avoids leaving the Simulink Editor. Open the Signal Properties dialog box for each signal.	"Use Simulink Editor to View Signal Logging Configuration" on page 59-68
Use the Signal Logging Selector.	Consider using this approach for models with deep hierarchies. View a model that has signal logging override settings for some signals. View the configuration as part of specifying a subset of signals for logging from all signals marked for signal logging.	"View Logging Configuration with Signal Logging Selector" on page 59-70

Signal Logging Configuration Viewing Approach	Usage	Documentation
	View signal logging configuration without displaying the signal logging indicators in the model. View signal logging configuration information such as decimation and output options in one window.	
Use the Model Explorer.	View signal logging configuration in the context of other model component properties. Adjust the column view to display signal logging properties, if necessary.	"Use Model Explorer to View Signal Logging Configuration" on page 59-72
Use MATLAB commands	Get the handles of the signals in the model and find the ones that have data logging enabled.	"Programmatically Find Signals Configured for Logging" on page 59-73

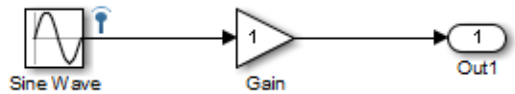
Use Simulink Editor to View Signal Logging Configuration

By default, Simulink Editor displays an indicator on each signal that is marked for signal logging. To view the signal logging setting for a signal:

1. Right-click the signal. From the context menu, select **Signal Properties**.
2. Select the **Logging and accessibility** tab.



For example, in the following model the output of the Sine Wave block is logged:



If you use the command-line interface to override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Configure a Signal for Logging” on page 59-59.

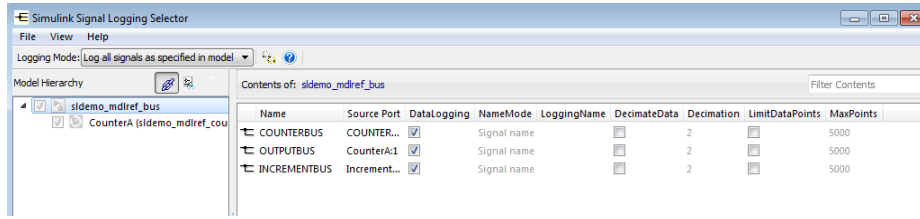
A logged signal can also be a test point. See “Test Points” on page 62-55 for information about test points.

To hide the logging indicators, clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

View Logging Configuration with Signal Logging Selector

1. Open the model for which you want to view the signal logging configuration.
2. Open the Signal Logging Selector, using one of the following approaches:
   - In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

     If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.
   - For a model that includes a Model block, you can also use the following approach:
     a. In the Simulink Editor, right-click a Model block.
     b. In the context-menu, select **Log Referenced Signals**.
3. In the **Model Hierarchy** pane, select the model node for which you want to view the signal logging configuration. For example:



To expand a node in the **Model Hierarchy** pane, right-click the arrow to the left of the node.

If no signals for a node are marked for signal logging, the **Contents** pane is empty.

For a model that references a model, the **Model Hierarchy** pane check box to the left of a model node indicates the override configuration of the node.

Check Box	Signal Logging Configuration
	For the top-level model node, logs all logged signals in the top model. For a Model block node, logs all logged signals in the model reference hierarchy for that block.
	For the top-level model node, disables logging for all logged signals in the top model. For a Model block node, disables logging for all signals in the model reference hierarchy for that block.
	For the top-level model node, logs all logged signals that have the `DataLogging` setting enabled. For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the `DataLogging` setting enabled.

View Configuration of Subsystems and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

Node	Display Default
Subsystem	Displays subsystems all that include logged signals
Masked subsystem	Does not display masked subsystems
Linked library	Displays all subsystems that include logged signals

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see “Displaying Linked Library Subsystems” on page 12-13 and “Displaying Masked Subsystems” on page 12-13.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the icon or **View** > **Show All Subsystems**. This

subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.

- To display masked subsystems with logged signals, use the icon or **View > Show Masked Subsystems**
- To display linked libraries, use the icon or **View > Show Library Links**

Filtering Signal Logging Selector Contents

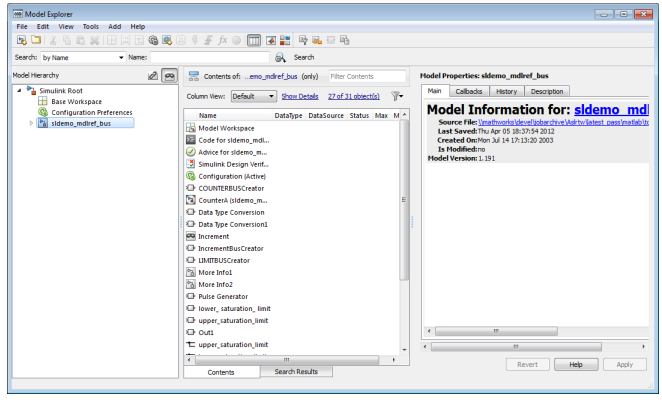
To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see “Filtering Contents” on page 12-47.

Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

Use Model Explorer to View Signal Logging Configuration

1. To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.
2. In the **Contents** pane, set **Column View** to the `Signals` view.



For further information, see “Model Explorer: Model Hierarchy Pane” on page 12-9 and “Model Explorer: Contents Pane” on page 12-19.

Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```
mdlsignals = find_system(gcs,'FindAll','on','LookUnderMasks','all',...
        'FollowLinks','on','type','line','SegmentType','trunk');
ph = get_param(mdlsignals,'SrcPortHandle')
for i=1: length(ph)
    get_param(ph{i},'datalogging')
end
```

- “View Logging Configuration with Signal Logging Selector” on page 59-70

Enable Signal Logging for a Model

In this section...
“Enable and Disable Logging at the Model Level” on page 59-74
“Migrate Scripts That Use `ModelDataLogs` API” on page 59-74
“Specify a Name for Signal Logging Data” on page 59-77

Enable and Disable Logging at the Model Level

To log a signal, mark it for signal logging. For details, see “Configure a Signal for Logging” on page 59-59.

Enable or disable logging globally for all signals that you mark for signal logging in a model. By default, signal logging is enabled. Simulink logs signals only if **Configuration Parameters > Data Import/Export > Signal logging** parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

To disable signal logging, use *one* of these approaches.

- Clear the **Configuration Parameters > Data Import/Export > Signal logging** parameter.
- Use the `SignalLogging` parameter. For example:

  ```
  set_param(bdroot,'SignalLogging','off')
  ```

Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 59-78.

Migrate Scripts That Use `ModelDataLogs` API

For scripts that simulate a model created in a release earlier than R2016a that uses `ModelDataLogs` format for logging, update the code to log in `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `Simulink.ModelDataLogs.convertToDataset` function to update the `ModelDataLogs` signal logging data to use `Dataset` format. For example, to update the `older_model_dataset` from `ModelDataLogs` format to `Dataset` format:

```
new_dataset = logsout.convertToDataset('older_model_data')
```

Converting a model from using `ModelDataLogs` format to using `Dataset` format can require that you modify your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues to address after converting to `Dataset` format. The table provides solutions for each issue.

Possible Issue After Conversion to Dataset Format	Solution

Code in existing callbacks, functions, scripts, or tests that used the `ModelDataLogs` programmatic interface to access data can result in an error.	Check for code that uses `ModelDataLogs` format access methods. Update that code to use `Dataset` format access methods.
	
	For example, suppose that existing code includes the following line:
	
	`logsout.('Subsystem Name').X.data`
	
	Replace that code with a `Dataset` access method:
	
	`logsout.getElement('x').Values.data`

Logging bus signals requires a configuration parameter change.	Logging buses in `Dataset` format requires that **Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** is set to `error`. To configure a model for proper bus usage, run the Upgrade Advisor with the **Check bus usage** check.
Mux block signal names are lost.	The `Dataset` format treats Mux block signals as a vector. To identify signals by signal names, replace Mux blocks with a Bus Creator blocks. Set **Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** to `error`.

Possible Issue After Conversion to Dataset Format	Solution
Signal Viewer cannot be used for signal logging.	Simulink does not log signal logging data in the Signal Viewer. Use the signal logging output variable to view the logged data.
The `unpack` method generates an error.	The `unpack` method, which is supported for `Simulink.ModelDataLogs` and `Simulink.SubsysDataLogs` objects, is *not* supported for `Simulink.SimulationData.Dataset` objects. For example, if the data in `mlog` has three fields: `x`, `y`, and `z`, then: • For `ModelDataLogs` format data, the `mlog.unpack` method creates three variables in the base workspace. • For `Dataset` format data, access methods by names. For example: `x = logsout.getElement('x').Values`
The `ModelDataLogs` and `Dataset` formats have different naming rules for unnamed signals.	If necessary, add signal names. • In `ModelDataLogs` format, for an unnamed signal coming from a block, Simulink assigns a name in this form: `SL_BlockName+<portIndex>` For example, `SL_Gain1`. • In `Dataset` format, elements do not need a name, so Simulink leaves the signal name empty. • For both `ModelDataLogs` and `Dataset` formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.

Possible Issue After Conversion to Dataset Format	Solution
Test points in referenced models are not logged.	Consider enabling signal logging for test points in a referenced model.
Script uses `who` or `whos` functions.	Consider using `Simulink.SimulationData.Dataset.find` instead.

Specify a Name for Signal Logging Data

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is `logsout`. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name `car_logsout` to identify the data as being the signal logging data for the `car` model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the **Configuration Parameters > Data Import/Export > Signal logging** parameter, enter the signal logging name.
- Use the `SignalLoggingName` parameter, specifying a signal logging name. For example:

```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```

Override Signal Logging Settings

In this section...

"Benefits of Overriding Signal Logging Settings" on page 59-78
"Two Interfaces for Overriding Signal Logging Settings" on page 59-78
"Scope of Signal Logging Setting Overrides" on page 59-79
"Override Signal Logging Settings with the Signal Logging Selector" on page 59-79
"Override Signal Logging Settings from MATLAB" on page 59-85

Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

Override signal logging properties to reduce memory overhead and to facilitate the analysis of simulation logging results. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- "Override Signal Logging Settings with the Signal Logging Selector" on page 59-79
- "Override Signal Logging Settings from MATLAB" on page 59-85

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when

saving the override settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` class has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to `Log all signals as specified in model`, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to `Override signals`. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

Note: Simulink rebuilds a model in the following situation:

1. The model contains one or more signals marked for signal logging.
2. You simulate the model in Rapid Accelerator mode.
3. You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
4. You simulate the model in Rapid Accelerator mode again.

Override Signal Logging Settings with the Signal Logging Selector

1. Open the Signal Logging Selector, using one of the following approaches:

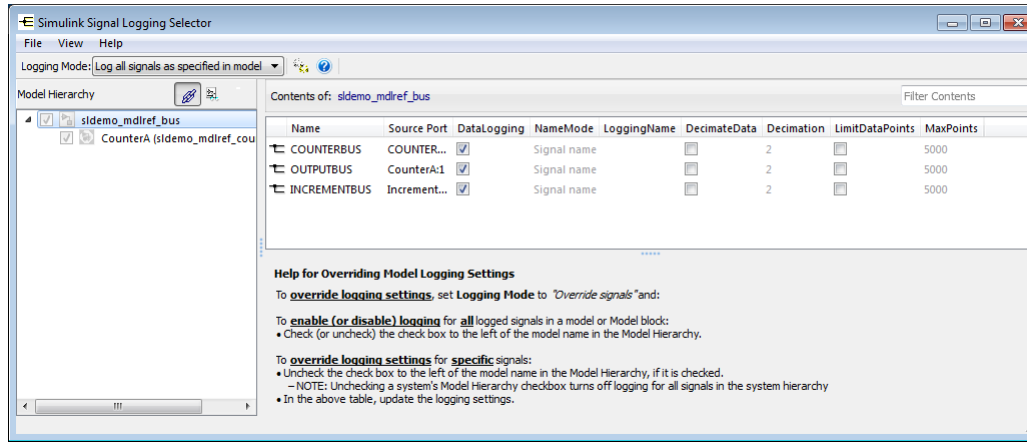
- In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

  If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- For a model that includes a Model block, you can also use the following approach:

  a In the Simulink Editor, right-click a Model block.

  b In the context-menu, select **Log Referenced Signals**.



2 Set **Logging Mode** to `Override signals`.

Note: The `Override signals` setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

---

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.

4 Override signal logging settings. Use one of the following approaches, depending on whether or not your model uses model referencing:

- "Models Without Model Referencing: Overriding Signal Logging Settings" on page 59-81
- "Models with Model Referencing: Overriding Signal Logging Settings" on page 59-82

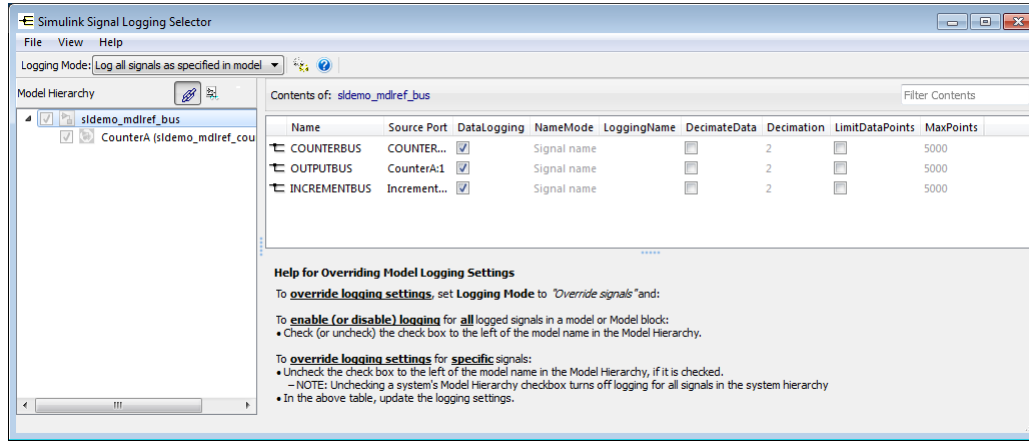
Tip To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the button.

Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

1. Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

   - If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.



2. Set **Logging Mode** to `Override signals`.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.

4 In the **Contents** pane table, select the signal whose logging settings you want to override.

5 Override logging settings:

- To disable logging for a signal, clear the `DataLogging` check box for that signal.
- To override other signal logging settings (for example, decimation), ensure that the `DataLogging` check box is selected. Then, edit values in the appropriate columns.

Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using the one or more of the following procedures:

- "Enable Logging for All Logged Signals" on page 59-82
- "Disable Logging for All Logged Signals in a Model Node" on page 59-83
- "Override Signal Logging for a Subset of Signals" on page 59-83
- "Override Other Signal Logging Properties" on page 59-84

Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is either solid ( ), if logging is disabled for some of signals, or empty ( ), if logging is disabled for all of the signals.

To enable logging of all logged signals for a node:

1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

2 Set **Logging Mode** to `Override signals`.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.

4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ( ).

- For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
- For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

Disable Logging for All Logged Signals in a Model Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is either solid ( ), if logging is enabled for some signals, or checked ( ), if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

2 Set **Logging Mode** to `Override signals`.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.

4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ( ).

- For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
- For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected reference model.

Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

1. Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.
4. In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid ( ), if logging is disabled for some of the signals, or empty ( ), if logging is disabled for all the signals. Click the check box to cycle through different states.
5. In the **Contents** pane table, for the signals that you want to log, select the check box in the `DataLogging` column.

   To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the `DataLogging` column of one of the highlighted signals.

Note: You cannot use the Signal Logging Selector to override a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

You can override programmatically a subset of signals in those configurations. For details, see "Override Signal Logging Settings from MATLAB" on page 59-85.

Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

1. Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.

3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-70.
4. In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid ( ) if logging is disabled for some signals, or empty ( ), if logging is disabled for all signals. Click the check box to cycle through different states.
5. In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the `DataLogging` column.

   To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the `DataLogging` column of one of the highlighted signals.
6. In the **Contents** pane table, modify the settings for properties, such as `DecimateData` and `Decimation`.

Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The `DataLoggingOverride` model parameter — Use to view or set signal logging override values for a model
- The following classes:
  - `Simulink.SimulationData.ModelLoggingInfo` — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
  - `Simulink.SimulationData.SignalLoggingInfo` — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:

  - `Simulink.SimulationData.LoggingInfo` — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the `DataLoggingOverride` parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use `set_param` with the `DataLoggingOverride` model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- "Create a Model Logging Information Object" on page 59-86
- "Specify Which Models to Log" on page 59-87
- "Log a Subset of Signals" on page 59-88
- "Override Other Signal Logging Properties" on page 59-90

Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a `Simulink.SimulationData.ModelLoggingInfo` object. For example, use the following commands to create the model logging override object for the `ex_bus_logging` model and automatically add each logged signal in the model to that object:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging')
```

```
mi =

  ModelLoggingInfo with properties:

                    Model: 'ex_bus_logging'
              LoggingMode: 'OverrideSignals'
    LogAsSpecifiedByModels: {}
                  Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `OverrideSignals`, which configures the model logging override object to log only the signals specified in the `Signals` property.

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

Specify Which Models to Log

Use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object to specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model, as described in the `Simulink.SimulationData.ModelLoggingInfo` documentation.

The following example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo...
     ('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'
```

```
mi =

  ModelLoggingInfo with properties:

                    Model: 'ex_bus_logging'
```

```
             LoggingMode: 'LogAllAsSpecifiedInModel'
    LogAsSpecifiedByModels: {}
                   Signals: []
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo...
     ('ex_bus_logging');
mi.LoggingMode = 'OverrideSignals';
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging',true);
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Log a Subset of Signals

For a simple model with a limited number of logged signals, you could create an empty `Simulink.SimulationData.ModelDataLogInfo` object. Then create `Simulink.SimulationData.SignalLoggingInfo` objects for each of the signals that you want to log, and assign those objects to the model logging information object.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mdl = 'ex_bus_logging';
blk = 'ex_bus_logging/IncrementBusCreator';
blkPort = 1;

load_system(mdl);

ov = Simulink.SimulationData.ModelLoggingInfo(mdl);
```

```
so = Simulink.SimulationData.SignalLoggingInfo(blk,blkPort);

ov.Signals(1) = so;

% apply this object so the model
set_param(mdl,'DataLoggingOverride',ov);

% Simulate
sim(mdl);

% observe that only the signal
topOut
```

To apply the model override object settings, use:

```
set_param(mdl, 'DataLoggingOverride', ov);
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by :

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
 'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));

mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
             'ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
                     'ex_mdlref_counter_bus/Bus Creator'}, 1)
```

```
pos =

     4
```

```
for idx=1:length(mi.Signals)
  mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);
end
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Note: You can override programmatically a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

To log a subset of signals for these model reference variant systems, set the `SignalLoggingSaveFormat` parameter to `Dataset`.

Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
 'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
    ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
                     'ex_mdlref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

- "Override Signal Logging Settings with the Signal Logging Selector" on page 59-79

Access Signal Logging Data

In this section...
"View Signal Logging Data" on page 59-92
"View Data in Simulation Data Inspector" on page 59-92
"Signal Logging Object" on page 59-93
"Access Data Programmatically" on page 59-93
"Handling Spaces and Newlines in Logged Names" on page 59-94
"Access Logged Signal Data in `ModelDataLogs` Format" on page 59-96

View Signal Logging Data

You can view the signal logging data for a paused or completed simulation, using one of these interfaces:

- The Simulation Data Inspector
- Programmatically, using MATLAB commands

Tip If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see "View the Signal Logging Configuration" on page 59-67 and "Override Signal Logging Settings" on page 59-78.

View Data in Simulation Data Inspector

You can use the Simulation Data Inspector to view data for signals marked for logging.

1. Open the model.
2. Select **Simulation > Output > Send Logged Workspace Data to Data Inspector**.
3. Select **Simulation > Output > Simulation Data Inspector**.
4. Simulate the model.

For additional information about using the Simulation Data Inspector, see “Inspect Signal Data with Simulation Data Inspector” on page 26-2.

Signal Logging Object

Simulink saves signal logging data in a `Simulink.SimulationData.Dataset` object, which is a MATLAB workspace variable. The default name of the signal logging variable is `logsout`. You can change the variable name. For details, see “Specify a Name for Signal Logging Data” on page 59-77.

Releases earlier than R2016a also supported a `ModelDataLogs` format. For details, see “Migrate Scripts That Use `ModelDataLogs` API” on page 59-74.

Access Data Programmatically

You can use the `Simulink.SimulationData.Dataset` API to access signal logging data programmatically. To access `Dataset` object elements, use the `get` method. For example, you can access the first element of the `topOut` signal logging `Dataset` object using get with an index.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_mdlref_counter_bus')));
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_bus_logging')));
sim('ex_bus_logging')
topOut
```

```
topOut =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'topOut'
    Total Elements: 4

  Elements:
    1: 'COUNTERBUS'
    2: 'OUTPUTBUS'
    3: 'INCREMENTBUS'
    4: 'inner_bus'
```

```
  -Use get or getElement to access elements by index, name or
   block path.
  -Use addElement or setElement to add or modify elements.

  Methods, Superclasses

element1 = topOut.get(1)

element1 =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
              Name: 'COUNTERBUS'
    PropagatedName: ''
         BlockPath: [1x1 Simulink.SimulationData.BlockPath]
          PortType: 'outport'
         PortIndex: 1
            Values: [1x1 struct]

  Methods, Superclasses

element1.Values

ans =

      data: [1x1 timeseries]
    limits: [1x1 struct]
```

To search for specific elements in a `Dataset` object, use the `find` method. To return the names of the `Dataset` object elements, use the `getNames` method.

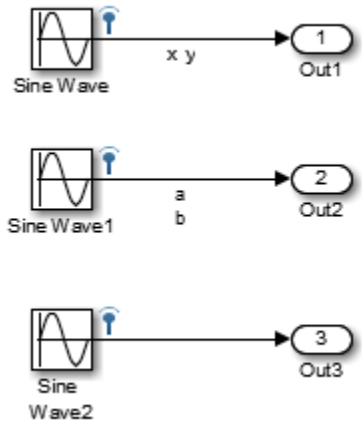
Handling Spaces and Newlines in Logged Names

Signal names in data logs can have spaces or newlines in their names when:

- The signal is named and the name includes a space or newline character.
- The signal is unnamed and originates in a block whose name includes a space or newline character.
- The signal exists in a subsystem or referenced model (or any parent block) whose name includes a space or newline character.

The following three examples show signals whose names contain:

- A space
- A signal whose name contains a newline
- An unnamed signal that originates in a block whose name contains a newline



The following example shows how to handle spaces or new lines in logged names when a model uses the default of `logsout` for the signal logging data.

```
logsout
```

```
logsout =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'logsout'
    Total Elements: 3

  Elements:
    1: ''
    2: 'x  y'
    3: 'a
b'
```

To access a signal with a space or newline, use the index. For example, to access the `x y` signal:

```
>> logsout.getElement(2)
```

Access Logged Signal Data in `ModelDataLogs` Format

Before R2016a, you could log signals in `ModelDataLogs` format. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format.

However, you can use data that was logged in a previous release using `ModelDataLogs` format.

For more information, see `Simulink.ModelDataLogs`.

Overview of Signal Loading Techniques

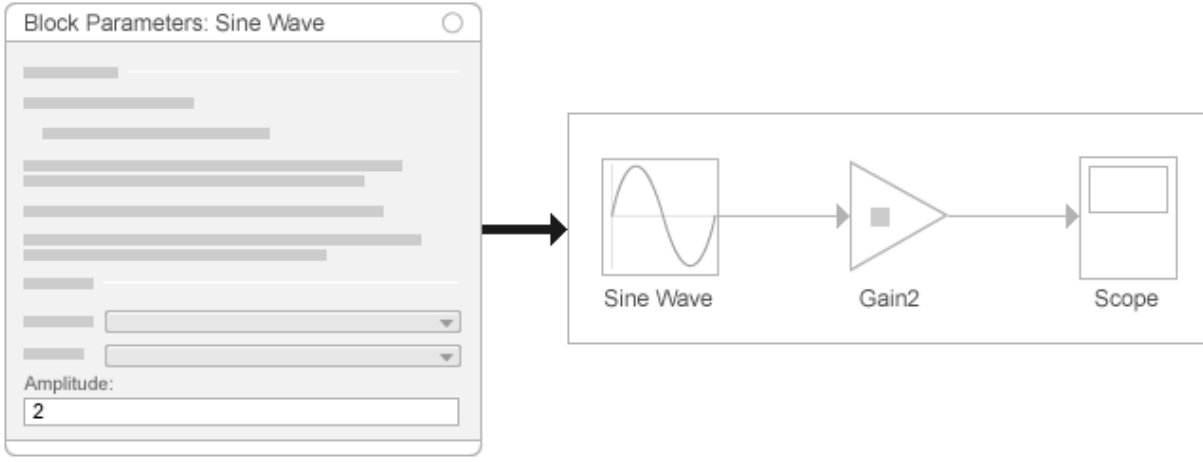
In this section...
“Source Blocks” on page 59-97
“Root-Level Input Ports” on page 59-98
“From File Block” on page 59-100
“From Spreadsheet Blocks” on page 59-101
“From Workspace Blocks” on page 59-102
“Signal Builder Blocks” on page 59-103

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 59-107.

Source Blocks

You can add a source block, such as a `Sine Wave` block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the `Sine Wave` Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.



The output data types of source blocks vary. For example, a `Sine Wave` block outputs a vector of real doubles.

For an example of using a source block, see "Build a Simple Model" on page 1-22.

Recommended Uses

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements
- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

Limitations

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

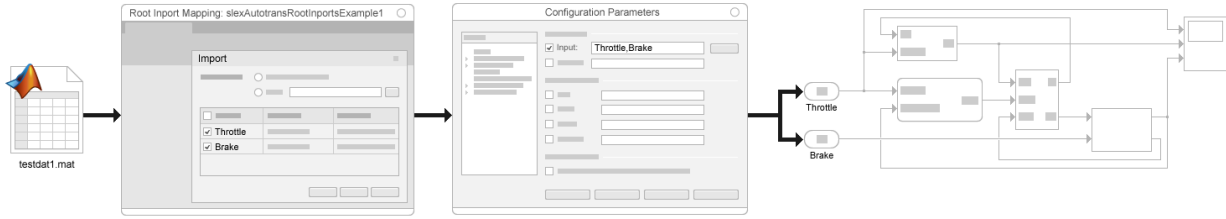
Root-Level Input Ports

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- `Enable`
- `Inport`
- `Trigger` block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter or a `sim` command argument. For an example, see "Import Data to Model a Continuous Plant" on page 59-121.

To import many signals to root-level input ports, consider using the Root Inport Mapping tool. This tool updates the **Input** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see "Map Data Using Root Inport Mapping Tool" on page 59-113.



Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the **Configuration Parameters** > **Data Import/Export** > **Additional parameters** > **Output options** parameter to `Produce additional output`.

Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.
- The Root Inport Mapping tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 59-163.

From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For an example, see “From File Block Loading Timeseries Data”.

Recommended Uses

Consider using a From File block for loading:

- Large amounts of data. For a Version 7.3 MAT-file, the From File block loa1qds data incrementally from the MAT-file during simulation.

  Tip To convert a Version 7.0 file to Version 7.3 (for example, `my_data_file.mat` that contains the variable `var`), at the MATLAB command line, enter:

  ```
  load('my_data_file.mat')
  save('my_data_file.mat', 'var', '-v7.3')
  ```

- Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.

- Data stored in a MAT-file that is separate from the model file.

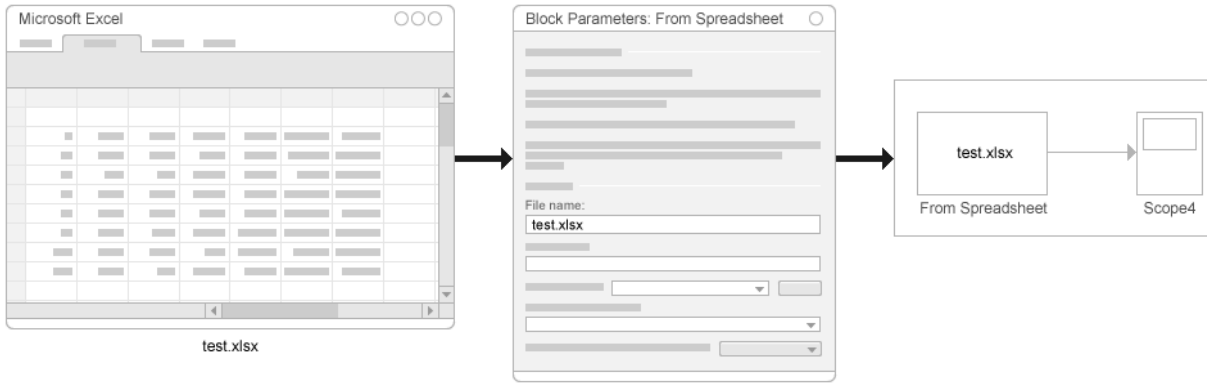
Limitations

- For *Version 7.0* or earlier MAT-file, the From File block reads only array-format data.

- Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently. See “MAT-File Variable” on page 59-136.
- The From File block supports reading nonvirtual bus signals in MATLAB `timeseries` format.
- For array data, the From File block reads only double signal data.
- Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation Requirements”.

From Spreadsheet Blocks

The `From Spreadsheet` block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.



Recommended Uses

Use the From Spreadsheet block for loading:

- Large Microsoft Excel or CSV spreadsheets. The `From Spreadsheet` block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
- Spreadsheets that you expect to modify. The `From Spreadsheet` block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.

Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in "Supported Microsoft Excel File Formats" on page 59-166.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

From Workspace Blocks

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the **Data** parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see "Use From Workspace Block for Test Case" on page 59-127.

Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals

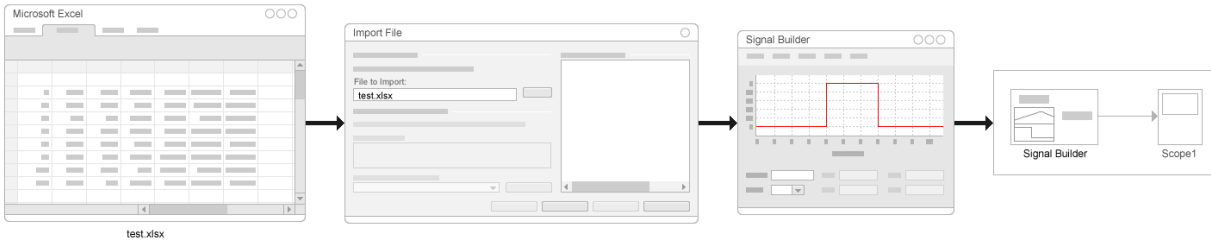
- Data that you saved using a To Workspace block in MATLAB `timeseries` format, without manual changes to the data
- Data saved in a previous simulation by a `To Workspace` block in either `Timeseries` or `Structure with Time` format for use in a later simulation

Limitations

- The data expressions that you specify must evaluate to one of these types of data:
  - A MATLAB `timeseries` object
  - A structure of MATLAB `timeseries` objects
  - An array or structure containing an array of simulation times and corresponding signal values

Signal Builder Blocks

Using a Signal Builder block, you can create interchangeable groups of piecewise linear signal sources to use in a model.



For examples of how to use a Signal Builder block, see:

- “Import Data for an Input Test Case” on page 59-126
- `sldemo_pid2dof`
- `sf_test_vectors`

Recommended Uses

Use the Signal Builder block to create and load signal groups to use in testing.

These products integrate the Signal Builder block into their workflows:

- Simulink Test
- Simulink Verification and Validation

Limitations

- The Signal Builder block has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in "Importing Signal Group Sets" on page 62-77.
- Data stores are not supported.
- The data type for signals must be `double`.

- "Comparison of Signal Loading Techniques" on page 59-105

Comparison of Signal Loading Techniques

In this section...
"Techniques" on page 59-105 "Impact of Loading Techniques on Block Diagrams" on page 59-106 "Comparison of Techniques" on page 59-107

Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source block, such as the `Sine Wave` block, to generate signal data as input to another block
- Root-level input ports (`Inport`, `Enable`, or `Trigger` block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapping tool. This section use "Root-level input ports" to address both approaches and "Root Inport Mapping tool" to refer specifically to that approach.
- `From File` block
- `From Spreadsheet`
- `From Workspace` block
- `Signal Builder` block

Suggested Signal Loading Techniques

Modeling Requirement	Suggested Signal Loading Technique
Signal values that Source blocks generate meet your requirements	Source block
Initial prototyping	From File, `From Spreadsheet`, or From Workspace block
System testing, sharing, and code generation	Root-level input port

Modeling Requirement	Suggested Signal Loading Technique
	You can use the Root Inport Mapping tool to create and map

For many models, loading signal data to a root inport block is an effective approach. The "Map Data Using Root Inport Mapping Tool" on page 59-113 provides a convenient way to load data for several signals to root inports.

To identify signal data loading techniques to meet specific modeling requirements, see "Comparison of Techniques" on page 59-107.

Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapping tool allows you to visualize the signal data that is loaded. For standalone systems that you want to test locally,

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the **Configuration Parameters > Data Import/Export > Input** parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapping tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

Test Harness Models

You can use a test harness models with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Builder block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapping tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness

models can be simpler to create than setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-180

Comparison of Techniques

Each technique addresses many of these modeling considerations:

- “Purpose of Importing Signal Data” on page 59-107
- “Signal Data” on page 59-108
- “Data Format or Type” on page 59-108
- “Bus Support” on page 59-109
- “Time Points” on page 59-110
- “Location for Data Storage” on page 59-110
- “Signal Data Inspection” on page 59-111
- “Handling of Loaded Data” on page 59-111
- “Simulation Mode” on page 59-111

Purpose of Importing Signal Data

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

Modeling Goal	Supported Techniques
Perform local, temporary testing by importing a small set of signal data	All From File, From Spreadsheet, and From Workspace blocks work well for this goal. Root-level input ports for reusable systems.
Test a model that you want to use as a referenced model	Root-level input ports
Verify a model by using multiple test cases	Root Inport Mapping tool, using exported signal data.

Modeling Goal	Supported Techniques
Represent a continuous plant	All Root-level input ports work well for this goal.
Test a discrete algorithm	All Root-level input ports work well for this goal.

Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

Signal Data	Supported Techniques
Large data set	From File or From Spreadsheet work well for large data sets, because they incrementally load the data.
Data exported by using a To File block	From File.
Data exported by using a To Workspace block	From Workspace.
Excel or CSV spreadsheet	From Spreadsheet or Signal Builder, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.
Variable-size signals	From Workspace.

Data Format or Type

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or `Dataset`). A few signal loading techniques have some limitations for specific formats.

Note: Some of the Root Inport Mapping tool map modes do not support all the data types that you can use with the tool. For details, see "Choose a Base Workspace and MAT-File Format" on page 59-163.

Data Format or Type	Supported Techniques
Array	All. For array data in a Version 7.0 MAT-file, the From File block loads only double signal values. Use Version 7.3 MAT-files for other types of signal data.
Structure with time	All.
Structure without time	All.
MATLAB `timeseries`	All.
`Simulink.SimulationData.Dataset`	All.
Enumeration	All except that Signal Builder can load, but not output enumerations.
Fixed-point	Signal Builder can load, but not output fixed-point data. From File has a word length limit of less than 33 bits.
Function-call	Root-level input ports (select the **Output function call** parameter).

Bus Support

You can use any of the signal loading techniques to load bus data. However, you need to use a specific technique for some kinds of bus data.

For the Signal Builder block,

Type of Bus or Bus Element	Supported Techniques
Virtual and nonvirtual buses	All techniques support both types of buses. The Root Inport Mapping tool does not support loading bus data in rapid accelerator mode.
Partial bus specification	For the Signal Builder block, the outputs for loaded bus data are either scalar double signals or a flat virtual bus.

Type of Bus or Bus Element	Supported Techniques
	From File uses ground values for unspecified bus elements.
Array of buses signals	Root-level input ports.

Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

Time Points for Signal Data	Supported Techniques
Single time point	All.
Continuous	All.
Discrete	All.
Repeated sequence without time	Structure data by using root-level input ports and From Workspace

Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

Location	Supported Techniques
In a block	Signal Builder block
In the base or model workspace	• From Workspace block • Root-level input ports or a Trigger, Enable, or Function-Call Subsystem block
In a MAT-file separate from the model file	From File block
In an Excel or CSV spreadsheet	From Spreadsheet block. **Tip**

Location	Supported Techniques
	• For Excel and CSV spreadsheet requirements, see “Storage Formats” on page 59-135. • Loading CSV data is supported only for Microsoft Windows platforms. You can use a Signal Builder block to import data from a spreadsheet. However, that block loads all the spreadsheet data into MATLAB memory and stores the data in the model. The From Spreadsheet incrementally loads the data directly from the spreadsheet.

Signal Data Inspection

The Root Inport Mapping tool, From File block, and Signal Builder block each provide an interface for plotting and inspecting the signal data to load.

Handling of Loaded Data

How Simulink processes the signal data as it loads it into a model impacts the signal logging technique that you choose.

Data Loading Handling	Supported Techniques
Incremental data loading	From File and From Spreadsheet.
Interpolation	All.
Extrapolation	From File, From Spreadsheet, and From Workspace. For information about From Workspace extrapolation, see “Form output after final data value by”.
Zero-crossing detection	All except root-level input ports.
Fast restart	All techniques.

Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

Simulation Modes	Supported Techniques
Normal and accelerator	All.
Rapid accelerator	All, with these rapid accelerator exceptions: • Root —level input ports support only array and structure data. • From Workspace does not support `timeseries` format.
ERT/GRT	All. From Workspace and From File blocks are not tunable.
SIL or PIL	From Workspace block.
External mode	All. Root-level input ports do not load bus data in external mode.

Map Data Using Root Inport Mapping Tool

In this section...
"The Model" on page 59-113
"Create Signal Data" on page 59-114
"Import and Visualize Workspace Signal Data" on page 59-115
"Map the Data to Inports" on page 59-116
"Save the Mapping and Data" on page 59-117
"Simulate the Model" on page 59-117

Use the Root Inport Mapping tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping imports signal data meets most modeling requirements and maintains model flexibility.

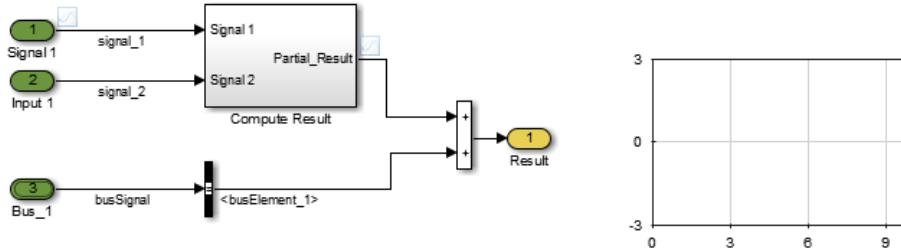
- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapping tool to update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapping tool:

1. Create signal data in the MATLAB workspace.
2. For a Simulink model, import the data from the workspace. You can visualize the data you import.
3. Map the data to root-level inports.
4. Simulate the model.
5. Save the Root Inport Mapping scenario.

The Model

This model has three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data. Open the model.



This example shows how you can use the Root Inport Mapping tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

Create Signal Data

You can define the signal data as MATLAB `timeseries` objects.

1. Define the time values for the signal data.

   ```
   sampleTime = 0.01;
   endTime = 10;
   numberOfSamples = endTime * 1/sampleTime +1;
   timeVector = (0:numberOfSamples) * sampleTime;
   ```

2. Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

   ```
   signal_1 = timeseries(sin(timeVector)*10,timeVector);
   signal_2 = timeseries(rand(size(timeVector)),timeVector);
   ```

3. Create the signals for the bus.

   ```
   busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
   busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
   ```

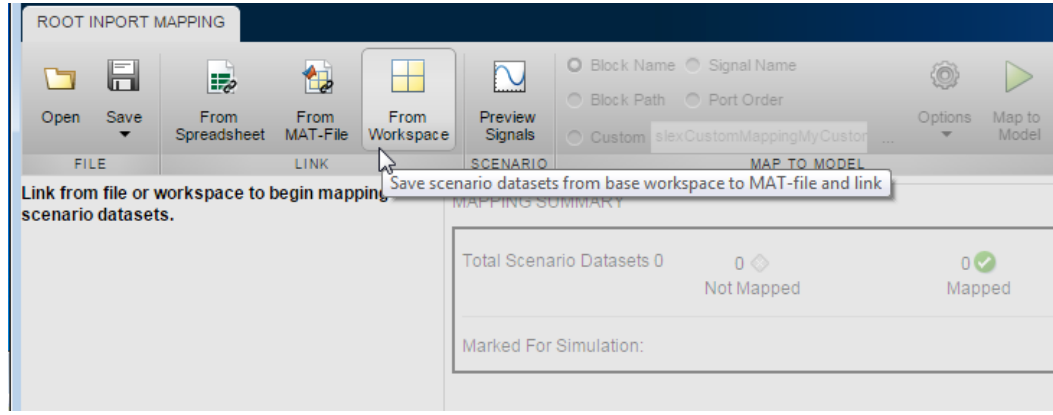
4. Create the bus object for the output data type of the `Bus_1` Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.

   ```
   busInfo = Simulink.Bus.createObject(busSignal);
   ```

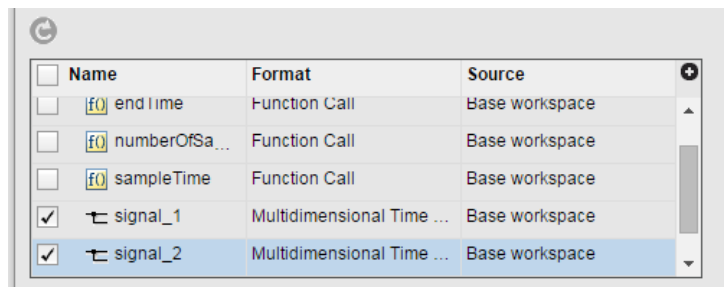
Import and Visualize Workspace Signal Data

Import the signal data that you created from the workspace into the Root Inport Mapping tool. Then you can use the tool to visualize the imported data.

1. Open the Root Inport Mapping tool. Open the Block Parameters dialog box for one of the Inport blocks in the model and click **Connect Input**.
2. In the Root Inport Mapping tool, select the **From Workspace** button.



3. In the Import dialog box, specify a MAT-file to save signals to. For this example, use the default.
4. Click the **Name** check box to clear the data variables. Then click the check boxes for the `busSignal`, `signal_1`, and `signal_2` signals.

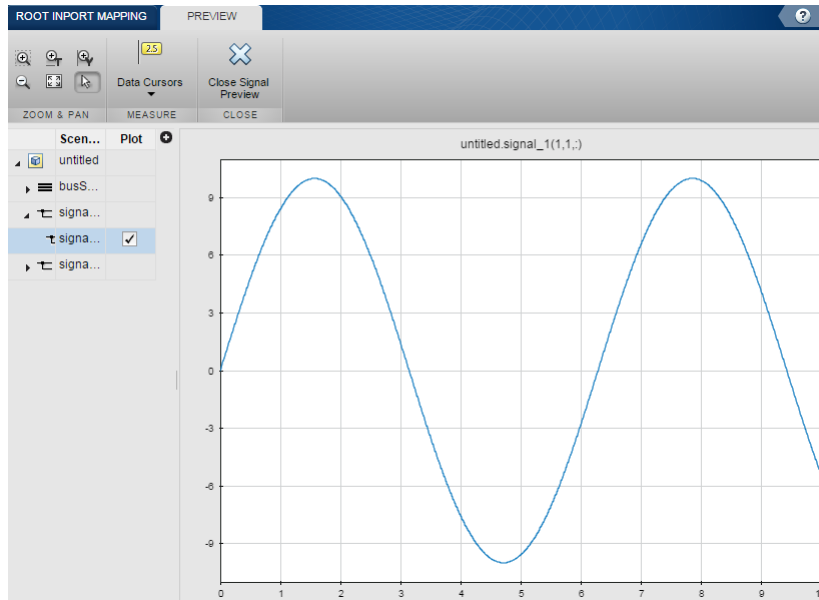


Although in this example you select all the signals, you can select a subset of signals.

5 Leave the **Convert signals into a scenario database and save to MAT-file** check box enabled and click **OK**.

6 You can visualize signals. In the Root Inport Mapping dialog box toolbar, click **Preview Signals**.

The **Preview** tab appears. You can select signals to plot. For example, to see a plot of `signal_1`, in the Navigation pane, expand the scenario data set (in this example, the top node, `untitled`) and then expand the `signal_1` entry. Select the check box for `signal_1(1,1,:)` to plot the data.



7 Close the **Preview** tab by clicking the **Close Signal Preview** button.

Map the Data to Inports

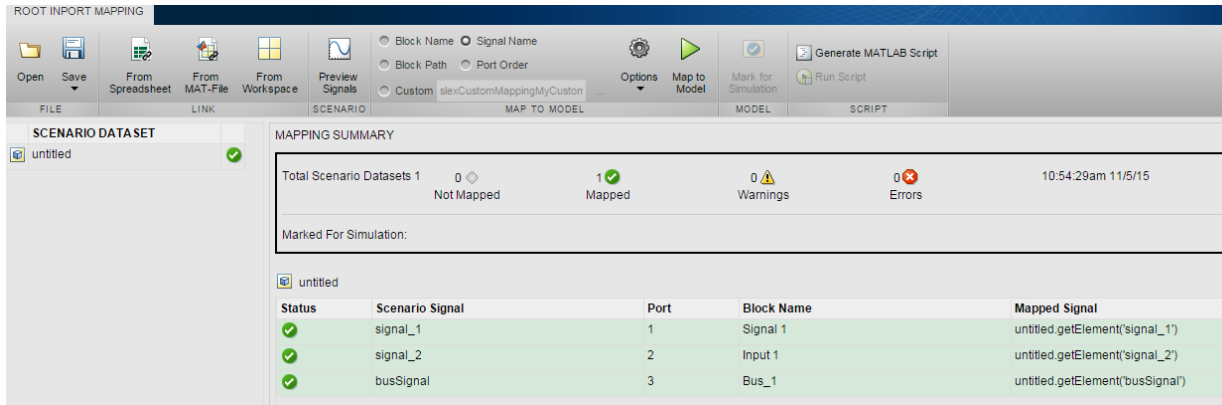
After you import the data, you map which data to use for specific Inport blocks.

1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select the **Signal Name** radio button.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.

2 You can specify options for the mapping. In the toolbar, select **Options**. Select **Compile**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.

3 Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Map to Model**. The dialog box shows the mapped data.



Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapping tool, click **Save** > **Save As** and save the scenario as an `.mldatx` file.

Simulate the Model

1 In the Navigation pane, select the scenario data set.

2 In the toolbar, click **Mark for Simulation**.

The model is now set up to simulate using the workspace signal data that you mapped to root—level Inport blocks.

3 Simulate the model.

This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

Log Simulation Data for Roundtrip Data Loading

In this section...
"Use Dataset Format for Consistent Logged Data" on page 59-119 "Limit the Scope of Logged Data" on page 59-120

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the **Configuration Parameters** > **Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see "Import Data to Model a Continuous Plant" on page 59-121.

Use Dataset Format for Consistent Logged Data

Different logging techniques support different data formats. Most logging techniques support the `Dataset` format, which provides a consistent data format for logged signal data. You can use the `Simulink.SimulationData.Dataset` constructor to convert other data formats to `Dataset` format.

Limit the Scope of Logged Data

To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

Related Examples

- "Save Runtime Data from Simulation"
- "Export Signal Data Using Signal Logging" on page 59-56

Import Data to Model a Continuous Plant

A continuous plant model uses signal data that is smooth and uninterrupted in time. There is signal data for each time value. A continuous plant model uses a continuous solver (any solver other than an explicit discrete solver). The solver can be fixed-step or variable. The model includes blocks from the Continuous library in Simulink, such as an Integrator block.

To load data to represent a continuous plant, consider using either a root-level input port or a From Workspace block. Using a From Workspace block can be useful when loading data to a port buried deep within a model.

For the signal data:

- Specify a time vector and signal values extracted from a continuous plant. For example, extract from data that you acquire experimentally or from the results of a previous simulation.
- Use any of the data formats listed in "Loading the Data" on page 59-145. Here are recommended formats for the following imported data sources:
  - Another simulation — `Dataset`
  - An equation — MATLAB time expression
  - Experimental data — MATLAB `timeseries`, structure with time, a structure without time, or a data array

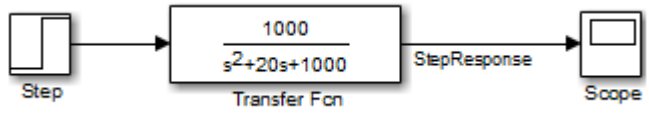
  For structure data, see "Specify Time Data" on page 59-216.

Use Simulation Data to Model a Continuous Plant

This example illustrates how to reuse signal logging data from the simulation of one model in the simulation of a second model. For more information, see "Load Signal Logging Data" on page 59-143.

When reusing data from a variable step size simulation for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

1 Open the ex_data_import_continuous model.



This model uses the `ode15s` solver and produces continuous signals.

2 To use the output of this model as input to the simulation of another model, log the signal that you want to reuse. In the Simulink Editor, select that signal, click the **Simulation Data Inspector** button arrow and click **Log Selected Signals to Workspace**.

Note: To enable signal logging, select the **Configuration Parameters** > **Data Import/Export** > **Signal logging** parameter. This model has **Signal logging** enabled.

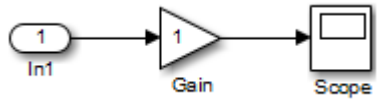
---

3 Simulate the model.

Simulating the model saves a variable-step signal to the workspace, using the `logsout` variable. The signal logging output is a `Simulink.SimulationData.Dataset` object.

Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logged data for individual signals is stored in `Simulink.SimulationData.Signal` objects. For this model, there is one logged signal: `StepResponse`.

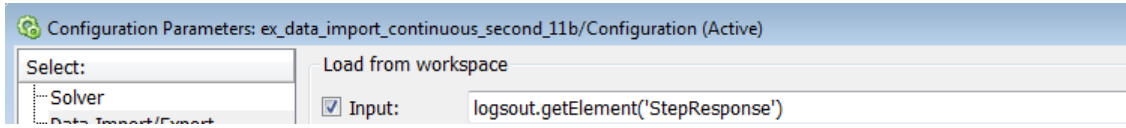
4 Open a second model, named ex_data_import_continuous_second.



You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to import the logged data. The Inport block has the **Interpolate data** option selected.

5 In the second model, select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

Use the `Simulink.SimulationData.Signal.getElement` method to specify the `StepResponse` signal element:



6 Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (`u`). In the Data Import/Export pane, set the **Output options** parameter to `Produce additional output` and the **Output times** parameter to:

```
logsout.getElement('StepResponse').Values.Time
```

7 Simulate the second model.

Note: Simulink does not feed minor time-step data through root input ports. For details about minor time steps, see "Minor Time Steps" on page 3-22.

More About

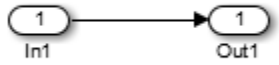
- "Overview of Signal Loading Techniques" on page 59-97

Import Data to Test a Discrete Algorithm

Discrete signals are signals that you define using evenly-spaced time values. One signal value is read at each time step, using the sample time of the source block.

Use a structure that has an empty time vector, which results in the model using the sample time of the source block. Using this approach avoids possible mismatches between the vector and the Simulink time steps. The double-precision rounding used by computers and the values expected by Simulink can differ.

Suppose you want to import signal data for this very simple model.



1. In the Block Parameters dialog box for the Inport block:
   - Set the sample time.
   - Clear the **Interpolate data** parameter.
2. For the data that you want to import, specify a structure variable that does *not* include a time vector. For example, for the variable called `import_var`:

   ```
   import_var.time = [];
   import_var.signals.values = [0; 1; 5; 8; 10];
   import_var.signals.dimension = 1;
   ```

   The input for the first time step is read from the first element of an input port value array. The value is `0`. The value for the second time step is read from the second element of the value array (`1`), and so on.

   For details about how to specify the signal value and dimension data, see "Specify Signal Data" on page 59-215.
3. Select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter and specify `import_var` for the data to import.

If you are using a From Workspace block to import data, use a similar approach. In addition, set the **Form output after final data value by** parameter to a value other than `Extrapolation`.

Import Data for an Input Test Case

In this section...
"Guidelines for Importing a Test Case" on page 59-126
"Example of Test Case Data" on page 59-127
"Use From Workspace Block for Test Case" on page 59-127
"Use Signal Builder Block for Test Case" on page 59-128

For most input test cases, you try to minimize the number of time points. The signal data you load includes samples with ramps and discontinuities.

Guidelines for Importing a Test Case

Typically when importing a test case data, you want to minimize the number of time points. The test data focuses on discontinuities in the signal data.

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Builder block, all of which support zero-crossing detection.

You can load data of these types:

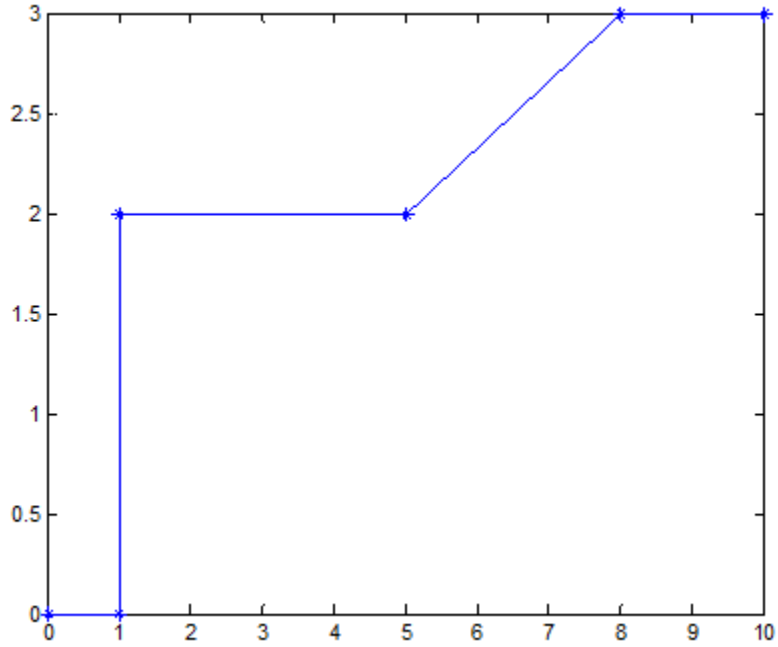
- A `Simulink.SimulationData.Dataset`
- Array
- `Simulink.SimulationData.Signal`
- Structure
- A structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression

Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps. For details about specifying a time vector, see “Specify Time Data” on page 59-216.

Use any of the input data formats described in “Loading the Data” on page 59-145, except for MATLAB time expressions.

Example of Test Case Data

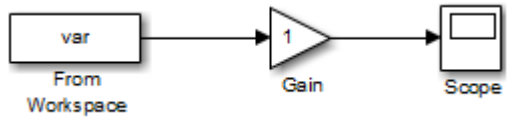
The following is an example of test case data:



The following two examples use this test case data.

Use From Workspace Block for Test Case

1 Open the model ex_data_import_test_case_from_workspace.



2 Enable zero-crossing detection. In the From Workspace block dialog, select **Enable zero-crossing detection**. Zero-crossing detection allows you to capture discontinuities accurately.

3 Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector, which generates a zero crossing and forces the variable-step solver to take a time step at this exact time. For details, see "Load Data Using the From Workspace Block" on page 59-202.

Define the `var` structure representing the test case:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
```

4 To import the test case structure, in the From Workspace block dialog box, in the **Data** parameter, specify `var`.

5 Simulate the model. The Scope block reflects the test case data.

Use Signal Builder Block for Test Case

Instead of using a From Workspace block, you can use a Signal Builder block to either:

- Create a signal interactively
- Import a signal from a MAT-file

1 Open the ex_data_import_signal_builder model.

2 Create a structure and save it in a MAT-file:

```
var.time = [0 1 1 5 5 8 8 10];
```

```
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
var.signals.label = 'var';
save var.mat var
```

3. Open the Signal Builder dialog box by double-clicking the Signal Builder block.
4. Select **File** > **Import From File** menu item, and select the `var.mat` file.
5. In the **Select** parameter, select `Replace existing dataset`. In the **Data to Import** section, select the **Select All** check box. Confirm the selection and click **OK**.

   The Signal Builder block display reflects the test case data.

Specify Data for Root-Level Input Ports

In this section...
“Root-Level Input Ports” on page 59-130
“Specify Input Data” on page 59-131
“Forms of Input Data” on page 59-132
“Time Data for the Input Parameter” on page 59-132

Root-Level Input Ports

Using a root-level input port to load signal data meets many modeling requirements. This technique is useful for importing many signals to many blocks and testing your model as a referenced model in a wider context with signals from the workspace, without modifying your model.

You can import signal data from a workspace and apply it to these blocks:

- `Inport` block
- `Enable` block
- `Trigger` block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapping tool. If you use that tool, you do not need to enter values in the **Input** parameter. The tool updates the **Input** parameter based on the signal data you import and the mapping you specify. For more information, see “Map Root Inport Signal Data” on page 59-159.

You can also import data from a workspace using a From Workspace block. For details, see the `From Workspace` documentation and “Import Data for an Input Test Case” on page 59-126.

Specify Input Data

1. Select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.
2. Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see "Forms of Input Data" on page 59-132.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at runtime for each simulation time step using the input `u = UT(t)` for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using:
  - A `Simulink.SimulationData.Dataset` object. Specify only one `Dataset` object.
  - A 2D array of input values and time for all input ports, in the form `UT = [T, U1, ... Un]`, where `T = [t1, ..., tm]'`
  - A comma-separated list of variables or MATLAB expressions. Do not include a `Dataset` object in a comma-separated list.

Comma-Separated List

If you specify `Dataset` data, specify only one `Dataset` object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression corresponds to a specific input port. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponding to the first root-level input port, the second to the second root-level input port, and so on.

For an `Enable` or `Trigger` block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Forms of Input Data

The input data can take these forms:

- `Simulink.SimulationData.Dataset` object — Collection of logged data in MATLAB `timeseries` format. For details, see "Create Dataset Data for Root Inport Ports" on page 59-205.
- MATLAB `timeseries` — For details, see these sections:
  - "Create MATLAB Timeseries Data for Root Inports" on page 59-207
  - "Import Bus Data to Top-Level Input Ports" on page 59-147
- Array — See "Create Data Arrays for Root-Level Inports" on page 59-209.
- `Simulink.SimulationData.Signal` — For details, see "Log Simulation Data for Roundtrip Data Loading" on page 59-119.
- Structure — To simplify the specification of external data to input, you can load data for a subset of root-level input port blocks. This avoids having to create data structures for the ports for which you want to use ground values. For information about ground values, see "Initialize Signals and Discrete States" on page 62-47. See "Create Data Structures for Root Inports" on page 59-214.
- Structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — See "Create MATLAB Time Expressions for Root Inports" on page 59-213.

Time Data for the Input Parameter

Time values that you specify in the **Input** parameter have no impact on the times the solver uses. The **Interpolate** parameter setting for the root-level input block (for example, the root-level `Inport` block) specifies how to handle output at time steps for which no corresponding workspace data exists.

“Bus Data” on page 59-136
“MAT-File Variable” on page 59-136

Data Saved by a To File Block

The From File block loads data that was written by a `To File` block without any modifications to the data or any other special provisions.

Supported MAT-File Versions

The supported MAT-file versions are:

- Version 7.0 or earlier
- Version 7.3

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory when the simulation begins. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For more information about MAT-files, see “MAT-File Versions”.

Convert Version 7.0 and Earlier Version MAT-Files

If you have a Version 7.0 or earlier version MAT-file that you want to use with the From File block, consider converting the file to Version 7.3. Use a Version 7.3 MAT-file if you want the From File block to load data incrementally during simulation or you want to use MATLAB `timeseries` data. For example, to convert a Version 7.0 file named `my_data_file.mat` that contains the variable `var`, at the MATLAB command prompt, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

Storage Formats

When the From File block loads data from a MAT-file, that data must be stored in array format or as a MATLAB `timeseries` object.

Array Data

You can use the array format for only vector, double, noncomplex signal data.

For a Version 7.0 MAT-file, the From File block loads array data, but not MATLAB `timeseries` data.

The array format for stored data is a matrix containing two or more rows. The matrix in the MAT-file must have the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u1_1 & u1_2 & \dots & u1_{final} \\ \dots & & & \\ un_1 & un_2 & \dots & un_{final} \end{bmatrix}$$

The first element of each column contains a timestamp. The remainder of each column contains data for the corresponding output values. Each element must be a double. Elements cannot include a NaN, Inf, or -Inf.

MATLAB Timeseries Data

To use bus data with a From File block, use the MATLAB `timeseries` format.

MATLAB `timeseries` format data can have:

- Any dimensionality and complexity
- Any built-in data type, including `Boolean`
- A fixed-point data type with a word length of up to 32 bits
- An enumerated data type

For data stored using the array format, the width of the From File output depends on the number of rows in the matrix. For a matrix containing m rows, the block outputs a vector of length m–1.

The MATLAB `timeseries` format supports the following simulation and code generation modes:

- Normal
- Accelerator
- Rapid accelerator
- Model reference accelerator

See the From File block documentation for an example of creating a MAT-file with MATLAB `timeseries` data load with a From Workspace block.

Timestamps

The timestamps in the file must be monotonically nondecreasing.

Bus Data

The From File block supports loading nonvirtual bus signals.

The data must be in a MATLAB structure that matches the bus hierarchy. Each leaf of the structure must be a MATLAB `timeseries` object.

The structure can underspecify the bus signal, but must not overspecify the bus signal. The structure cannot have any elements that do not have corresponding signals in the bus.

The structure does not require a `timeseries` object for every element in the bus hierarchy. However, the structure must have a `timeseries` object for at least one of the signals in the bus. For signals that do not specify data, the From File block outputs the ground values.

MAT-File Variable

If a MAT-file contains only one variable, then the From File block uses that variable. If the MAT-file contains more than one variable:

- For Version 7.3 MAT-files, the From File block uses the variable that is first alphabetically.
- For Version 7.0 or earlier MAT-files, the From File block uses the first variable. However, for these versions, the ordering algorithm for variables is complicated. Use a MAT-file that contains just the variable with the data that you want the From File block to load.

Create Data for a From Workspace Block

In this section...
"Use Data from a To Workspace Block" on page 59-138
"Specify Variable-Size Signals" on page 59-138
"Data for the From Workspace Block" on page 59-138
"Bus Data" on page 59-141
"Use Data from a To File Block" on page 59-142

Use Data from a To Workspace Block

You can use the From Workspace block to load data exported by a `To Workspace` block in a previous simulation for use in a later simulation. Save the To Workspace block data in either `Timeseries` or `Structure with Time` format.

Specify Variable-Size Signals

You can use a To Workspace block (with `Structure` or `Structure With Time` format) or a root Outport block to log variable-size signals. Then use the To Workspace variable with the From Workspace block.

Alternatively, create a MATLAB structure that contains variable-size signal data. For each `values` field in the structure, include a `valueDimensions` field that specifies the run-time dimensions for the signal. For details, see "Simulink Models Using Variable-Size Signals" on page 64-6.

Data for the From Workspace Block

You can load these kinds of data using a From Workspace block:

- A MATLAB timeseries object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

To use workspace data that is in `Simulink.SimulationData.Dataset` format, extract a MATLAB `timeseries` object from the data set. For example, if you use signal logging

with `Dataset` format and use the default output variable `logsout`, for a single logged signal enter:

```
logsout.get(1).values
```

MATLAB Timeseries Data

You can use a MATLAB `timeseries` object for any data type, complexity, or fixed dimensions.

Real signals of type `double` can be in any format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

Structure of MATLAB `timeseries` Data

Use a structure of MATLAB `timeseries` objects for bus data. Matche the bus hierarchy and specify a `timeseries` object for each leaf signal in the bus.

Structures

You can use a structure for one-dimensional or multidimensional signals, with or without time values. For the structure, use this format:

- A `signals.values` field, which contains a column vector of signal values.
- An optional `signals.dimensions` array, which contains the dimensions of the signal.
- An optional `time` vector of doubles, which is a column vector of timestamps.

  The nth `time` element is the timestamp of the nth `signals.values` element.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For examples, see:

- “Import Data to Test a Discrete Algorithm” on page 59-124
- “Use From Workspace Block for Test Case” on page 59-127

For both discrete and continuous signals, specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. For details, see "Specify Signal Data" on page 59-215.

Each `signals` substructure must contain two fields: `values` and `dimensions`.

- The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

  If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

  If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of your model input ports. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions `4-by-5-by-51`.
- The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value that specifies the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose first element specifies the number of rows in the matrix and whose second element specifies the number of columns.

For continuous signals, you can specify a `time` field, which contains a time vector. How you specify the time values depends on the kind of signal data that you want.

For information about defining MATLAB structures, see "Create a Structure Array" in the MATLAB documentation.

Signal Data	Time Data Recommendation
Evenly spaced discrete signals	Use an expression in this form: `timeVector = timeStep * [startTime:numSteps-1]'` The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you

Signal Data	Time Data Recommendation

	want minus 1. For example, to specify 50 time values at 0.2 time steps:
	`T1 = 0.2 * [0:49]'`
	Note: Do *not* use an expression in this form:
	`timeVector = [startTime:timeStep:endTime]'`
	For example, do not use:
	`T2 = [0:0.2:10]'`
	This time vector form is not equivalent to the form that multiplies by time steps (`T1`), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the `T2` form can lead to unexpected simulation results.

Unevenly spaced values	Use any valid MATLAB array expression; for example, `[1:5 5:10]` or `(1 6 10 15)`. The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.

Matrix

You can use a matrix to specify only one-dimensional signals.

The first element of each matrix row is a timestamp. The rest of each row is a scalar or vector of signal values.

Bus Data

To create bus data to load with a From Workspace block, use a structure of MATLAB `timeseries` objects. Match the bus hierarchy and specify a `timeseries` object for each leaf signal in the bus. Set up the data the same way as you do for loading bus signals to a

root-level input port. For details, see “Import Bus Data to Top-Level Input Ports” on page 59-147.

Use Data from a To File Block

Loading data that was exported to a file by a To File block using MATLAB `timeseries` does not require that you change the data.

If you set the To File block **Save format** parameter to `Array`, transpose the exported array data. The data saved by the To File block contains columns with consecutive timestamps, followed by the corresponding data. The transposed data contains rows with consecutive timestamps, followed by the corresponding data. To provide the required format, use MATLAB `load` and `transpose` commands with the MAT-file (see “Reshaping a Matrix”). To avoid transposing the data again later, resave the transposed data.

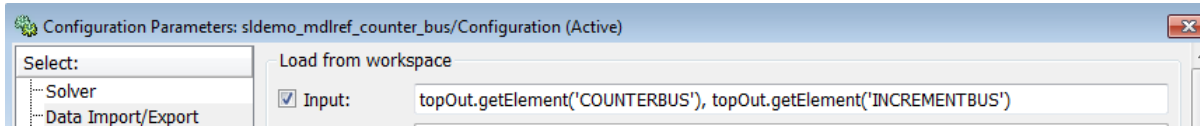
Load Signal Logging Data

You can use signal logging to log data for specified signals during simulation. Then you can load that saved simulation data as input for another simulation of that model (or the simulation of a different model). For example, using this approach is useful to perform standalone simulation of a referenced model.

1. Use the default signal logging output variable, `logsout`, or specify a variable using the **Configuration Parameters** > **Data Import/Export** > **Signal logging** edit box.
2. Simulate the parent model.

   The signal logging output is a `Simulink.SimulationData.Dataset` object.
3. Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
4. For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

   For example:



5. Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see the `sldemo_mdlref_bus` example. After you open the model, double-click the blue block labeled **Interface Specification** and see the sections called:

- Logging Model Reference Signals
- Loading Data

Open the `sldemo_mdlref_bus` model.

Also, the “Import Data to Model a Continuous Plant” on page 59-121 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 59-152.

Load Data to Root-Level Input Ports

You can load data from a workspace and apply it to a root-level:

- `Inport` block
- `Enable` block
- `Trigger` block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapping tool. For more information, see "Map Root Inport Signal Data" on page 59-159.

You can also import data from a workspace using a From Workspace block. For details, see the `From Workspace` documentation and "Import Data for an Input Test Case" on page 59-126.

Loading the Data

Use the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to load data from a workspace and apply it to the root-level input ports of a model during a simulation run.

Note: The use of the **Input** box is independent of the setting of the **Format** list on the **Data Import/Export** pane.

Simulink linearly interpolates or extrapolates input values as necessary if you select the **Interpolate data** option for the corresponding `Inport`, `Enable`, or `Trigger` block.

Simulink resolves symbols used in the external input specification as described in "Symbol Resolution" on page 4-97. See the documentation of the `sim` command for some data import capabilities that are available only for programmatic simulation.

Import Bus Data to Top-Level Input Ports

In this section...
"Imported Bus Data Requirements" on page 59-147
"Import Bus Data to a Top-Level Inport" on page 59-148
"Get Information about Bus Objects" on page 59-151
"Create Structures of Timeseries Objects from Buses" on page 59-151
"Import Array of Buses Data" on page 59-152

You can import bus data to top-level input ports by manually specifying the data in the **Configuration Parameters > Data Import/Export > Input** parameter or by using the Root Inport Mapping tool. For information about importing bus data using the Root Inport Mapping tool, see "Import Bus Data" on page 59-169.

Imported Bus Data Requirements

To import bus data to a top-level input port, use a structure of MATLAB `timeseries` objects. The `timeseries` objects represent the bus elements that you want to specify values for. Any bus elements for which you do not include a field in the structure use ground values. You can include a structure of `timeseries` objects as a `Dataset` object element.

In the top-level Inport block, set **Data type** to `Bus` and specify the name of a bus object.

A top-level input port defined by a bus object (see `Simulink.Bus`) can import data from a `Simulink.SimulationData.Dataset` object or from a structure of MATLAB `timeseries` objects. The `Dataset` object or structure represents the bus elements for which you want to specify values. Any bus elements for which you do not include a field in the structure use ground values.

The structure of MATLAB `timeseries` objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The `name` property of the `timeseries` object does not need to match the bus element name.)
- Data type (for tunable parameters)

- Dimensions
- Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Note: If you use a structure of MATLAB `timeseries` objects for a root Inport block in a model with multiple root Inport blocks, all root Inport blocks must use MATLAB `timeseries` objects. Convert any root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to MATLAB `timeseries` objects.

Initialize Bus Signals

You can initialize bus signals, including using partial specification of initialization data. For details, see "Specify Initial Conditions for Bus Signals" on page 63-78.

For details about importing array of bus data to a root Inport block, see "Import Array of Buses Data" on page 59-152.

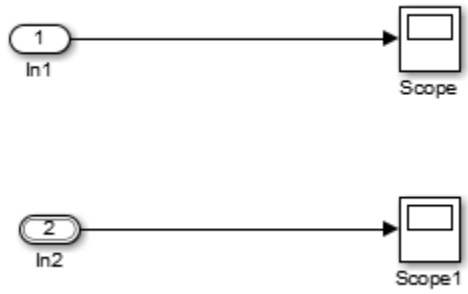
Limitations for Importing Bus Data to Top-Level Inputs

The signal data that you can use the Root Inport Mapping tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.

Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the `In1` block is inherited (nonbus data) and the data type of the `In2` block is defined by the bus object `BusObject`. The model has a callback that loads `BusObject`.



The `BusObject` bus object has two elements:

- `c`
- `s1`, which is a subbus that has two elements:
  - `a`
  - `b`

1. Open the .
2. Create a MATLAB `timeseries` object for `In1`, for which you want to import nonbus data.

   For example:

   ```
   t1 = (1:10)';
   d1 = sin(t1);
   in1 = timeseries(d1,t1);
   ```

3. Create a structure of MATLAB `timeseries` objects, with one `timeseries` object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the `b` bus element, so it does not need a `timeseries` object for that element.

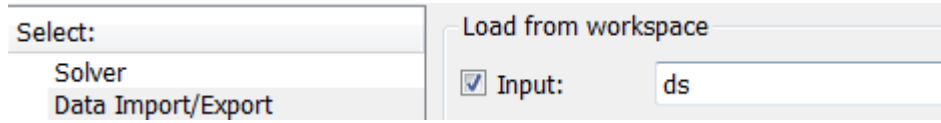
   ```
   t2 = (1:5)';
   d2 = cos(t2);
   in2.c = timeseries(d1,t1);
   in2.s1.a = timeseries(d2,t2);
   ```

The MATLAB `timeseries` objects that you create must match the corresponding bus elements, as described in "Imported Bus Data Requirements" on page 59-147.

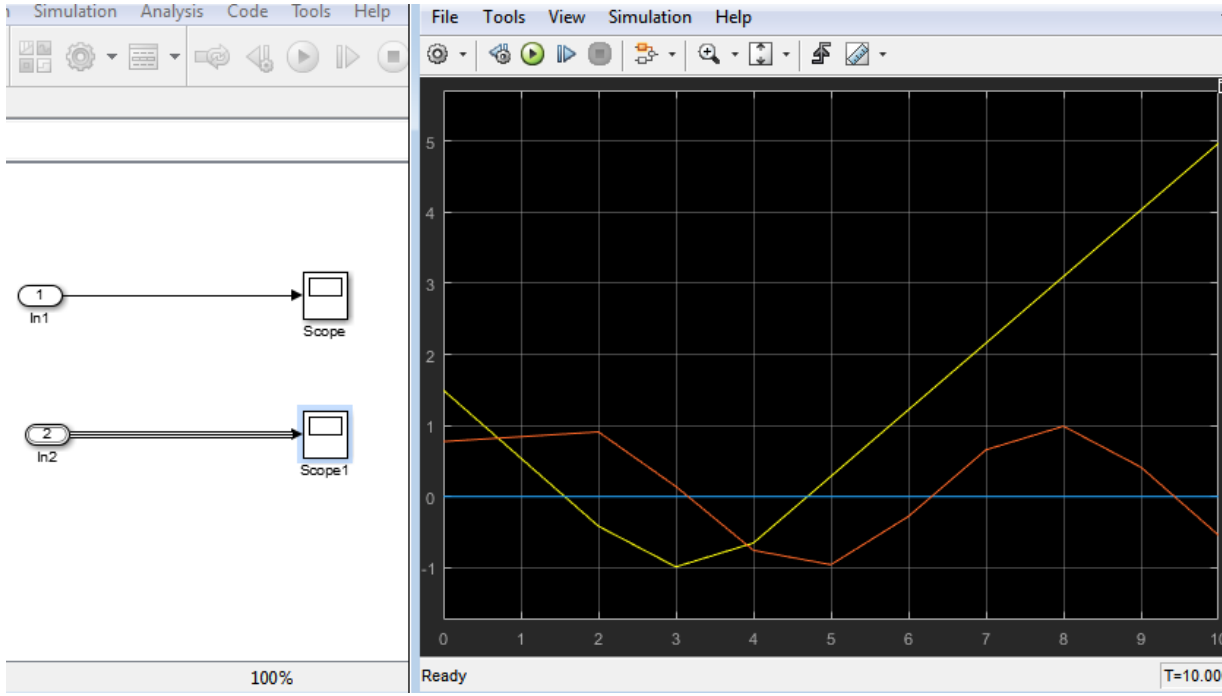
4 Create a `Dataset` object and add `in1` and `in2` to the data set.

```
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1,'in1_signal');
ds = ds.addElement(in2,'in2_signal');
```

5 In the **Configuration Parameters** > **Import/Export** > **Input** parameter edit box, enter the `Dataset` object `ds`.



6 Simulate the model. The Scope block connected to In2 shows the imported bus data.



Get Information about Bus Objects

To determine the number of MATLAB `timeseries` objects and data type, complexity, and dimensions needed for creating a structure of `timeseries` objects from a bus, use these methods:

- `Simulink.Bus.getNumLeafBusElements`
- `Simulink.Bus.getLeafBusElements`

For example, for the bus object `BusObject`:

```
num_el = BusObject.getNumLeafBusElements
```

```
num_el =

     3
```

```
el_list = BusObject.getLeafBusElements
```

```
el_list =

  3x1 BusElement array with properties:

    Min
    Max
    DimensionsMode
    SamplingMode
    SampleTime
    Description
    Units
    Name
    DataType
    Complexity
    Dimensions
```

```
el_list(1).Dimensions
```

```
ans =

     1
```

Create Structures of Timeseries Objects from Buses

If you have `timeseries` objects defined, you can use them to create a structure of `timeseries` objects based on a bus object. Use the

`Simulink.SimulationData.createStructOfTimeseries` function. For example, if you have defined `timeseries` objects `ts1`, `ts2`, and `ts3`, and you have a bus object `MyBusObject`, you can use this command to create a structure of `timeseries` objects:

```
input = Simulink.SimulationData.createStructOfTimeseries('MyBusObject',...
{ts1,ts2,ts3});
```

The number of `timeseries` objects in the cell array must match the number of leaf elements in the bus object . The data type, dimensions, and complexity of each `timeseries` object must match those attributes of the corresponding bus object leaf node.

Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB `timeseries` objects.

Note: You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

Full Specification of Data

You can use logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to specify fully the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

  For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

Partial Specification of Data

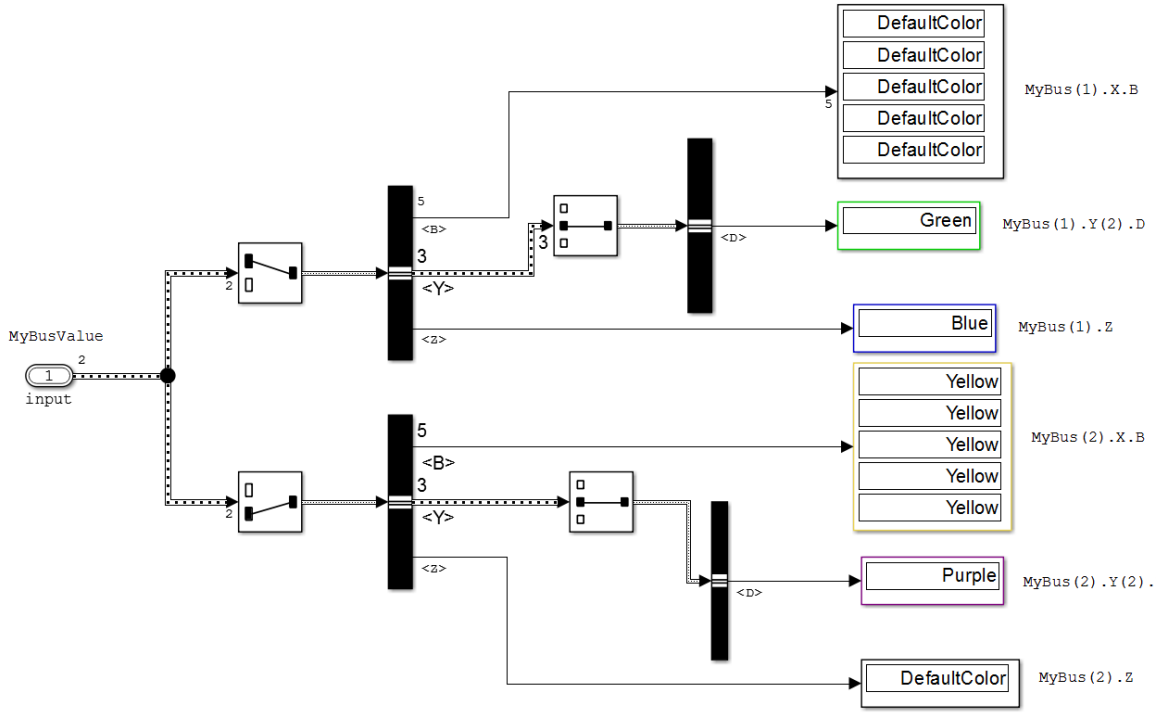
To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

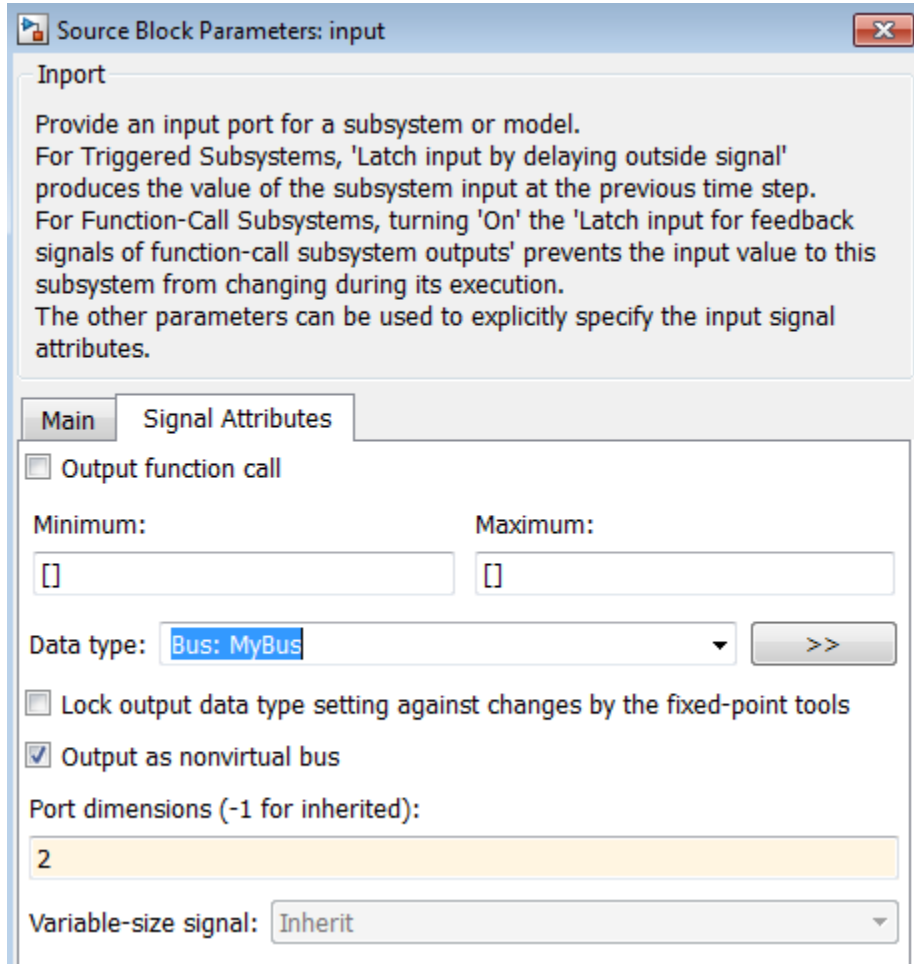
- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For subbus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object `MyBus`. You can open the model (`ex_partial_loading_aob_model`) and the MATLAB code that defines the data to import (ex_partial_loading_aob_data.m).

When you simulate `ex_partial_loading_aob_model`, you see:

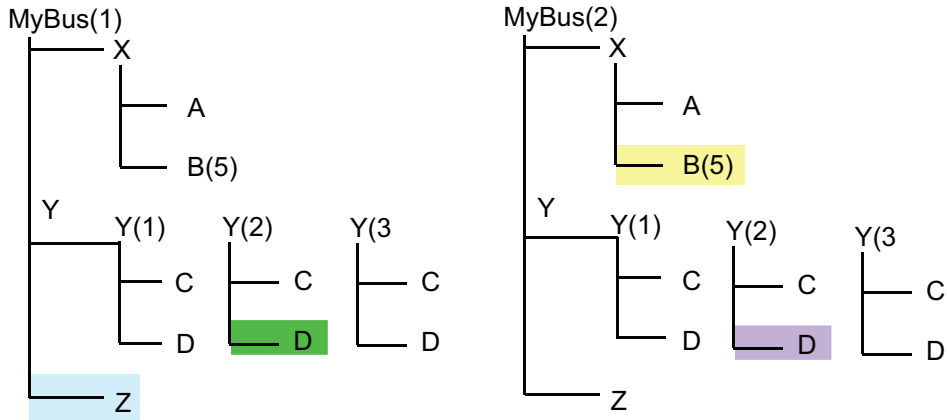


The `input` Inport block uses the `MyBus` bus object as its data type.



The `MyBus` array of buses includes `MyBus(1)` and `MyBus(2)`. The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes `MyBus(1)` and `MyBus(2)`. The color highlighting shows the nodes of the array of buses for which data is being imported.



Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file ex_partial_loading_aob_data.m.

```
%% Create timeseries data for leaf signals
N = 10; Ts = 1;
Time = ((0:N)*Ts)';
[m, n] = size(Time);

ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);

% Create individual timeseries objects to represent Z, B, D1 and D2
ZT = timeseries(ZData, Time, 'Name', 'Z');
BT = timeseries(BData, Time, 'Name', 'B');
D1T = timeseries(D1Data, Time, 'Name', 'D1');
D2T = timeseries(D2Data, Time, 'Name', 'D2');

%% Construct MyBusValue(1)

% Y(2).D
Y(2) = struct('D',D1T);

% Set X.B to empty to allow the second element to support specification for
% this field
X = struct('B',[]);

% MyBusValue(1)
MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
clear X Y;

%% Construct MyBusValue(2)

% Specify timeseries for MyBusValue(2).X.B
MyBusValue(2).X.B = BT;

% Specify timeseries for MyBusValue(2).Y(2).D
MyBusValue(2).Y(2).D = D2T;
```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.
- The structure specifies data for `Y(2)`. You can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

This example specifies data for `Y(2)`; you can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to `MyBusValue`.

Map Root Inport Signal Data

In this section...
"Open the Root Inport Mapping Tool" on page 59-159
"Command-Line Interface" on page 59-160
"Import and Mapping Workflow" on page 59-160
"Choose a Map Mode" on page 59-160

To import, visualize, and map signal and bus data to root-level inports, use the Root Inport Mapping tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level inports are ports of one of these blocks:

- `Inport` block
- `Enable` block
- `Trigger` block

Root-level inport blocks import data from the MATLAB workspace based on the value of the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data that you import and map to roo-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

You can also choose a signal data import technique that meets your modeling requirements, such as the data amount or storage location. For a comparison of data import methods, see "Comparison of Signal Loading Techniques" on page 59-105.

Open the Root Inport Mapping Tool

Use either of these approaches to open the Root-Inport Mapping tool:

- In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.
- In the block parameters dialog box for the Inport block, select **Connect Input**.

Command-Line Interface

You can use the `getRootInportMap` to create a custom object to map signals to root-level inports and `getSlRootInportMap` to create a custom mapping mode. For more information, see "Create and Use Custom Map Modes" on page 59-190.

Import and Mapping Workflow

1. Identify the signals that you want to import and map to the model root-level inports.
2. Import and inspect signal data.
3. Map the imported signal data. For example, you can map the signal data by block path or signal name.
4. Simulate the model using the mapped data.
5. Optionally, save:
   - Signal data for future reference or for other people to use
   - The current Root Inport Mapping scenario (session) for future reference or to share with other people

Tip To extend the Root Inport Mapping tool map modes, you can create a custom mapping file function to map data to root-level inports.

Choose a Map Mode

To specify how you want the Root Inport Mapping tool to map the signal data to a model, select from these map modes in the **MAP TO MODEL** section of the toolbar:

- Block name — Connect signal data to ports based the name of a root-inport block.
- Block path — Connect signal data to ports based the path of a root-inport block.
- Signal name — Connect signal data to ports based on the name of the signal on a port.

- Port order — Connect sequential port numbers to the imported data.
- Custom — Connect signal data to ports based on the definitions in a custom mapping file.

Each supported input format supports one or more mapping modes. To import MATLAB `timeseries` data, for example, you use any mapping mode . To import data array signal data, use the port order mapping mode.

Create Signal Data for Root Inport Mapping

In this section...
“Identify Signal Data to Import and Map” on page 59-162
“Choose a Naming Convention for Signal and Buses” on page 59-162
“Choose a Base Workspace and MAT-File Format” on page 59-163
“Bus Signal Data for Root Inport Mapping” on page 59-164
“Create Signal Data in a MAT-File for Root Inport Mapping” on page 59-165
“Supported Microsoft Excel File Formats” on page 59-166

Identify Signal Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import signal data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 59-163.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapping tool.

  For more information, see “Choose a Base Workspace and MAT-File Format” on page 59-163 and “Supported Microsoft Excel File Formats” on page 59-166.

Tip To import signal data from an Microsoft Excel spreadsheet, consider using the `From Spreadsheet` block. The `From Spreadsheet` block incrementally loads data from the spreadsheet during simulation. If you use a `From Spreadsheet` block, you do not need to do anything to handle changes to worksheet values.

Choose a Naming Convention for Signal and Buses

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (signal group) is interchangeable. For example, you can have two MAT-files whose data has different values but the same variable names. Then you can switch the groups of input data into and out of a model quickly.

Choose a Base Workspace and MAT-File Format

The Root Inport Mapping tool supports these MATLAB data types or formats for imported signal data. For each data type, you can use one or more mapping modes.

Data Formats	Block Name	Block Path	Signal Name	Port Order	Custom
`Simulink.SimulationData.Dataset`	✓	✓	✓	✓	✓
MATLAB `timeseries`	✓		✓	✓	✓
`Simulink.SimulationData.Signal`	✓	✓	✓	✓	✓
`Stateflow.SimulationData.State`	✓	✓	✓	✓	✓
Structure with time and structure without time				✓	
Data array				✓	
Array of buses	✓		✓	✓	✓
"Specifying Function-Call Inputs" on page 10-13	✓		✓	✓	✓

Note: If your MAT-file or base workspace contains data in a format that the Root Inport Mapping tool does not support, the tool ignores that data.

Note: Although the Root Inport Mapping tool accepts these formats, it can only link in a `Simulink.SimulationData.Dataset` object. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, in the Root Inport Mapping From dialog box, select the **Convert signals into a scenario dataset and save to MAT-file** check box. Alternatively, use the `convertToSlDataset` function to convert your data.

Dataset Signal Data

If data sets have nonunique element names, use the **Port Order** map mode.

MATLAB Timeseries Signal Data

If you have MATLAB timeseries data with enumeration, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

Array Signal Data

The Root Inport Mapping tool tries to map the data array to a single inport. In this case, you can choose any of the map modes.

Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level `Enable` or `Trigger` block.

1. In the MATLAB workspace, create or load a "Bus Objects" on page 63-27 for the bus data that you want to import and map.
2. If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.
3. Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:
   - Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.
   - Create the bus in the base workspace and then save it to a MAT-file.
4. Set up the model to load the bus object.
   - For root-level `Inport` blocks that you map signals to, set the **Data type** field to `Bus`. Specify the name of the variable for the bus object to be used for signal data mapping.
   - Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see "Alternative Workflows to Load Data" on page 59-186.

Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`), and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSlDataset` function convert MAT-files to `Simulink.SimulationData.Dataset` objects.

1. In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```
signal1 = Simulink.SimulationData.Signal;
signal1.Name = 'signal1';
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');
signal1.PortType = 'inport';
signal1.PortIndex = 1;

signal2 = Simulink.SimulationData.Signal;
signal2.Name = 'signal2';
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');
signal2.PortType = 'inport';
signal2.PortIndex = 2;

signal3 = Simulink.SimulationData.Signal;
signal3.Name = 'signal3';
signal3.BlockPath = Simulink.SimulationData.BlockPath('Out3');
signal1.PortType = 'inport';
signal1.PortIndex = 3;
```

2. In the MATLAB workspace, select `signal1`, `signal2`, and `signal3`. Right-click and in the context menu, click **Save as**. Save the file as `mySigData.mat`.

3. Open the MAT-file.

```
open mySigData.mat

ans =

    signal1: [1x1 Simulink.SimulationData.Signal]
    signal2: [1x1 Simulink.SimulationData.Signal]
    signal3: [1x1 Simulink.SimulationData.Signal]
```

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapping tool maps the signal data from the MAT-file to corresponding ports.

Supported Microsoft Excel File Formats

You can use the Root Inport Mapping tool to import signal data into Excel spreadsheets. You can also use the Root Inport Mapping tool to import signal data in CSV files on a Windows system with Microsoft Office installed.

- Each worksheet name must be a valid MATLAB variable name.
- For signal names, use the first row of a worksheet. Either specify a signal name for every signal or do not specify any signal names. If you do not specify any signal names, the tool assigns signal names by using the format `Signal#`.
- For time values, use the first column of the remaining rows. The time values must increase for each row.
- Put signal values in the remaining columns.

This example of an Microsoft Excel spreadsheet that is set up for root-inport mapping.

- The worksheet name is `sigData`, which is a valid MATLAB variable name.
- The first row contains the signal names `signal1`, `signal2`, and `signal3`.
- The first column has six time values.
- In each row with a time value, columns to the right of the first column contain signal data values for each signal.

	A	B	C	D	E
1		signal1	signal2	signal3	
2	0	2	4	6	
3	1	3	5	7	
4	2	2	4	6	
5	3	4	6	8	
6	4	5	7	9	
7	5	6	8	10	
8					
9

Import Signal Data for Root Inport Mapping

In this section...
“Import Signal Data” on page 59-168
“Import Bus Data” on page 59-169
“Import Signal Data from Other Sources” on page 59-170
“Import Test Vectors from Simulink Design Verifier Environment” on page 59-170

Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 59-162.

For data import purposes, the Root Inport Mapping From dialog box provides a **Convert signals into a scenario dataset and save to MAT-file** check box, selected by default. Select this check box to convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object. Alternatively, use the `convertToSlDataset` function to convert your data.

Note: The Root Inport Mapping uses the term *link* to refer to the act of importing Simulink data.

To import signal data for root-inport mapping:

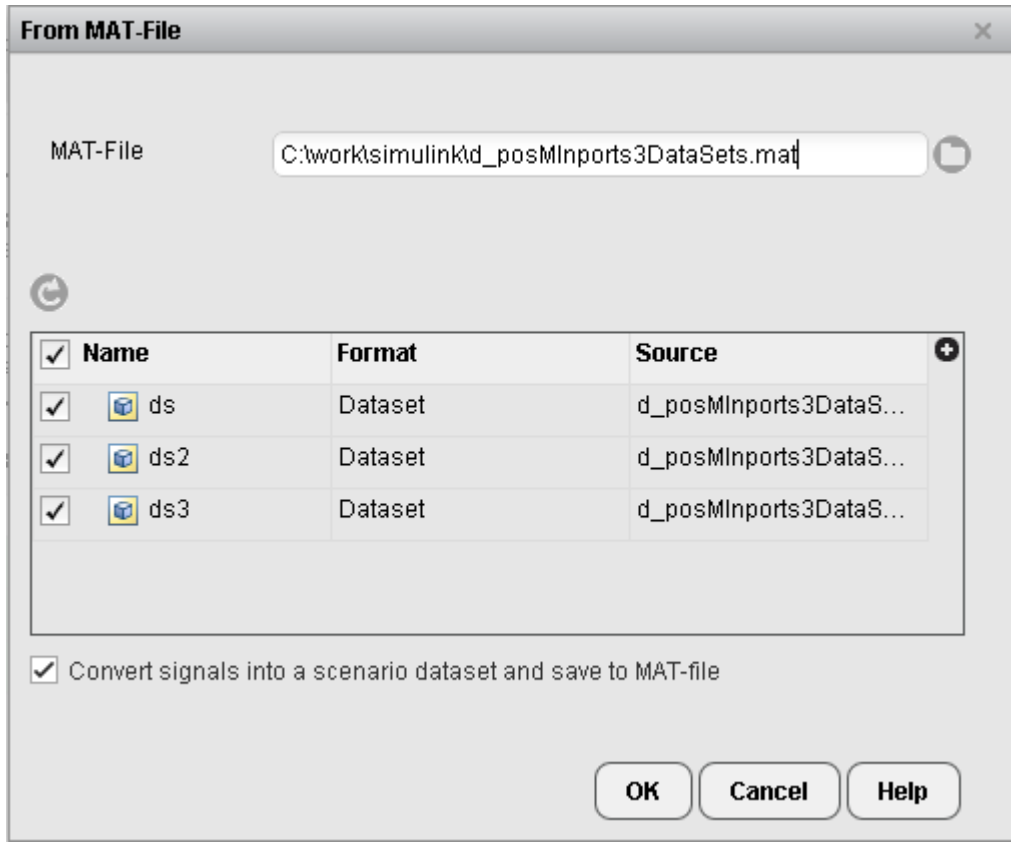
1. Open the Root Inport Mapping tool. In the **Configuration Parameters** > **Data Import/Export** pane, click **Connect Input**.
2. In the LINK section, select the data source.

   - To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select **From Spreadsheet** or **From MAT-File**. Click **Open** to return to the LINK section. Then click **OK**.

     Note: To import bus data for root inport mapping, see “Import Bus Data” on page 59-169.

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From MAT-File dialog box displays the contents of the spreadsheet, file, or base workspace.



3 Select the data that you want to import, and then click **OK**.

The Root Inport Mapping tool displays the imported data.

Import Bus Data

Use bus objects for bus data that you want to import and map to root inports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB `struct`, or you can create the bus in the base workspace and save it to a MAT-file. For more information, "Bus Signal Data for Root Inport Mapping" on page 59-164.

To import the bus data, in the LINK section of the Root Inport Mapping toolstrip, click **From MAT-File**. Select the MAT-file that contains the bus data and click **OK**.

Import Signal Data from Other Sources

Use the Root Inport Mapping tool to import signals from other sources.

- You can import Excel spreadsheet data. The Root Inport Mapping tool imports a worksheet as a `Simulink.SimulationData.Dataset` object that contains timeseries elements.
- To convert and import test vectors from Simulink Design Verifier, see "Import Test Vectors from Simulink Design Verifier Environment" on page 59-170.
- To import signals from models that contain `Signal Builder` blocks, see "Converting Harness-Driven Models to Use Harness-Free External Inputs" on page 59-180.

Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Import a MAT-file that contains a Simulink Design Verifier test vector structure `sldvData`.

The test vectors are converted during the import to a `Simulink.SimulationData.Dataset` supported by the Root Inport Mapping tool.

Alternatively, you can use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. Save the output to a MAT-file and then import that file into the Root Inport Mapping tool.

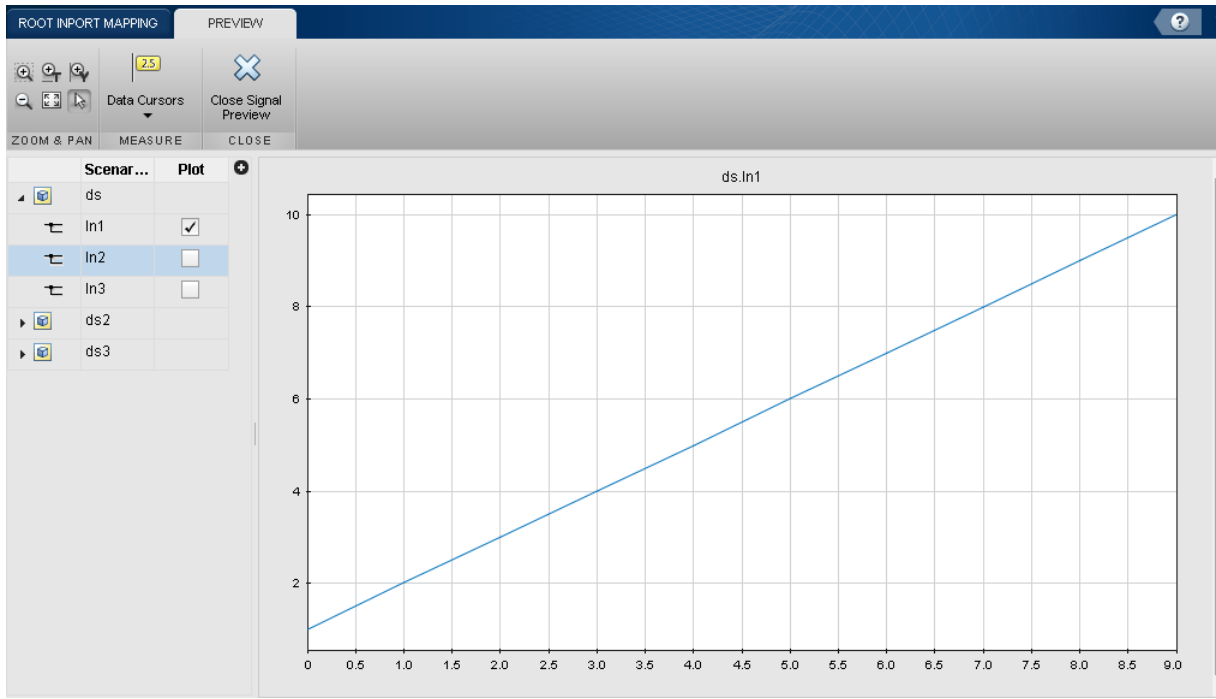
View and Inspect Signal Data

After you import signal or bus data, you can view and inspect signal data.

1. In the **ROOT INPORT MAPPING** tab, click **Preview Signals**.
2. To plot the signal, in the **Plot** column, select the check box next to the signal. If the format is a bus, click the expander (▸) to see and select the elements of the bus.



3. Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

   - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
   - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.

Map Signal Data to Root Inports

In this section...
“Select Map Mode” on page 59-174
“Set Options for Mapping” on page 59-175
“Map Data” on page 59-175
“Understand Mapping Results” on page 59-176
“Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-180
“Alternative Workflows to Load Data” on page 59-186

Select Map Mode

To map signal data to root-level ports, use one of these map modes in the MAP TO MODEL section of the Root Inport Mapping toolstrip.

Goal	Map Mode
Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-inport block, the data is mapped to the corresponding port.	**Block Name**
Assign signals to ports according to the block path of the root-inport block. If the block path of a signal matches the block path of a root-inport block, the data is mapped to the corresponding port.	**Block Path**
Assign signals to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, the signal is mapped to the corresponding port.	**Signal Name**
Assign sequential port numbers to the imported data, starting at 1. Map signals to the corresponding inports.	**Port Order**

Goal	Map Mode
• If there is more data than inports, the remaining data is mapped to enable and then trigger inports. • If the data is not in the form of a dataset, it is processed in the order in which it appears in the data file.	
Assign signals to ports according to the definitions in a custom file. To create a custom mapping mode, see "Create and Use Custom Map Modes" on page 59-190.	**Custom**

Set Options for Mapping

If you want to set up mapping options, in the MAP TO MODEL section on the Root Inport Mapping toolstrip, click **Options**. To map the signals, see "Map Data" on page 59-175.

Goal	Option
Compile the model and review the data types of root-level inports and imported data.	**Compile**. Compare the signal data and inport parameters to the root-level port and display the results. If you do not select this option, the tool maps the imported data to the root-level inport but does not compile the model. See "Understand Mapping Results" on page 59-176. If the data that is in the comparison window is inherited from the connected block, a warning appears.
Import bus data that is only partially defined.	**Allow partial**. Confirm that any partially specified bus data you import maps properly to root-level inports.

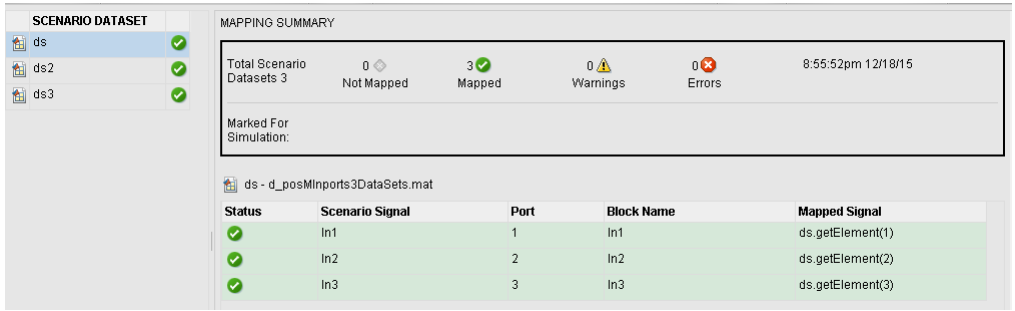
Map Data

After you import signals or buses, you can map data.

1 On the Root Inport Mapping toolbar, click **Map to Model**.

The results of a signal mapping appear in the **SCENARIO DATASET** tab.

2 In the FILE section, click a data set to see the mapping results



- The **MAPPING SUMMARY** tab lists the input data and the status of the mapping.

  Note: See "Understand Mapping Results" on page 59-176.

- The mapping definition for the input data is applied to the model.

After you save and close the model, when you load input data of the same signal group to the workspace, the model uses the mapping defined for that signal group.

For an example of mapping signal data to root-level inputs, see "Converting Harness-Driven Models to Use Harness-Free External Inputs" on page 59-180.

After you save the mapping definition for a model, you can automate data loading. For more information, see "Alternative Workflows to Load Data" on page 59-186.

Understand Mapping Results

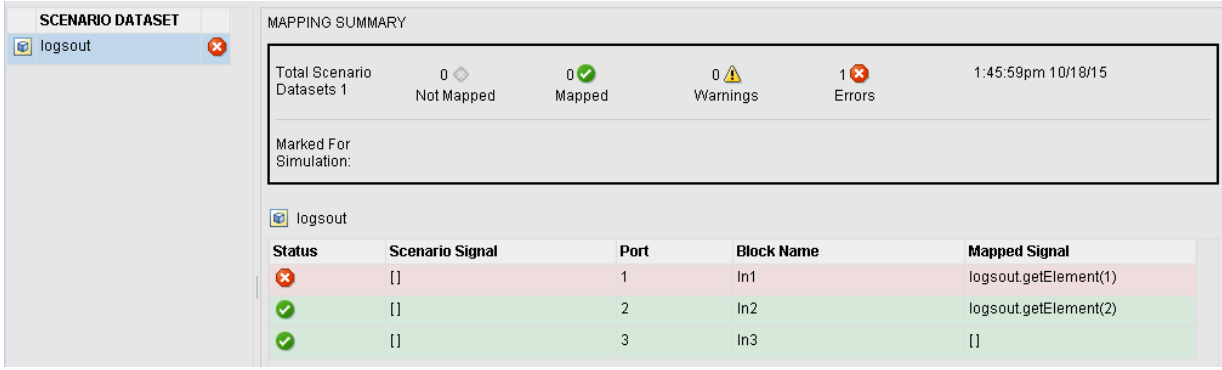
When you complete the import and map process, the **MAPPING SUMMARY** tab displays the results in the status area. The results depend on whether you select the **Compile** option when you set up the mapping.

Status	Compile	Continue Without Compile
✓	The properties of the mapped data and the inport are appropriate for simulation.	The data type, dimension, and signal type properties of the data and inport are compatible.

Status	Compile	Continue Without Compile
⚠	Not applicable	Comparison of data and root-level port data type, dimension, and signal type properties cannot determine whether there is a match. If you do not compile before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the inport data types. Confirm that you set these block parameters correctly: • `Inport` block parameter **Data type** is not set to `Inherit:auto`. • `Inport` block parameter **Dimension** is not set to `-1`. • `Inport` block parameter **Signal type** cannot be `auto`.
⊗	The properties of the mapped data and the inport are not appropriate for simulation.	One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level inport.

Root-level input ports that have not been mapped are displayed as empty ([]).

This figure shows mapping successes and failures.



In the Root Inport Mapping tool, clicking **Mark for Simulation** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box.

It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**.

This graphic illustrates the application of the changes to the model configuration for the model in "Map Data" on page 59-175.

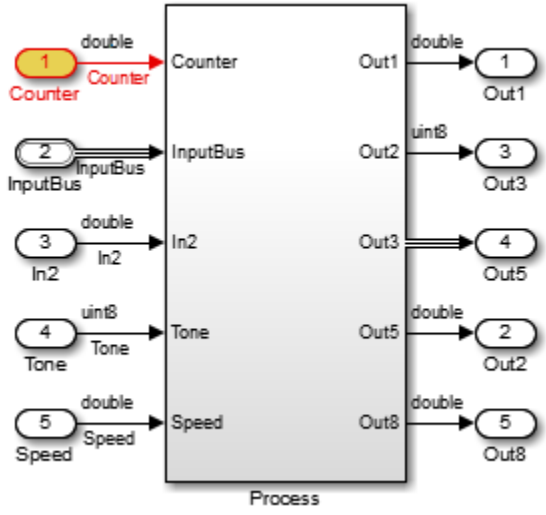
To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the **MAPPING SUMMARY** tab. If there are warnings or failures, the `Inport` block associated with the data appears highlighted in the model.

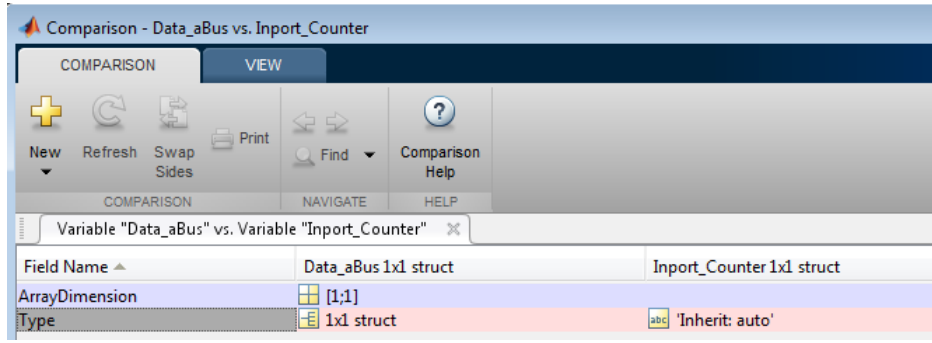
- Failures appear as yellow Inport blocks outlined with bold red.
- Warnings appear as yellow Inport blocks outlined in orange.
- Successes appear as normal Inport blocks outlined with blue.

When you select the Counter block name in the **MAPPING SUMMARY** tab, the Counter block in the model is highlighted. The highlighting indicates an error.



Use the Comparison Tool to evaluate your next action. The Comparison Tool shows the properties for the root-level inport and the signals that you are trying to map to the inport. You can tell from this table whether there is a mismatch that prevents the mapping. For example, if there is a mismatch, you can update the imported signals or edit the root-level inport. When you are done, reimport the data to map it.

To investigate warnings and failures, in the **MAPPING SUMMARY** tab, click the line item that you want to inspect. The Comparison Tool lists the selected variable, including the field name, input data, and root-level inport.



Note: When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

Sometimes the Comparison Tool shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Compile** check box from the **Options** menu, select it and click **Map** again.

Tip Each time you click a nongreen status item, a new Comparison Tool instance appears. To dock all Comparison Tool instances in one window, click the **Dock** button .

For more information on the Comparison Tool, see “Comparing Files and Folders”.

Converting Harness-Driven Models to Use Harness-Free External Inputs

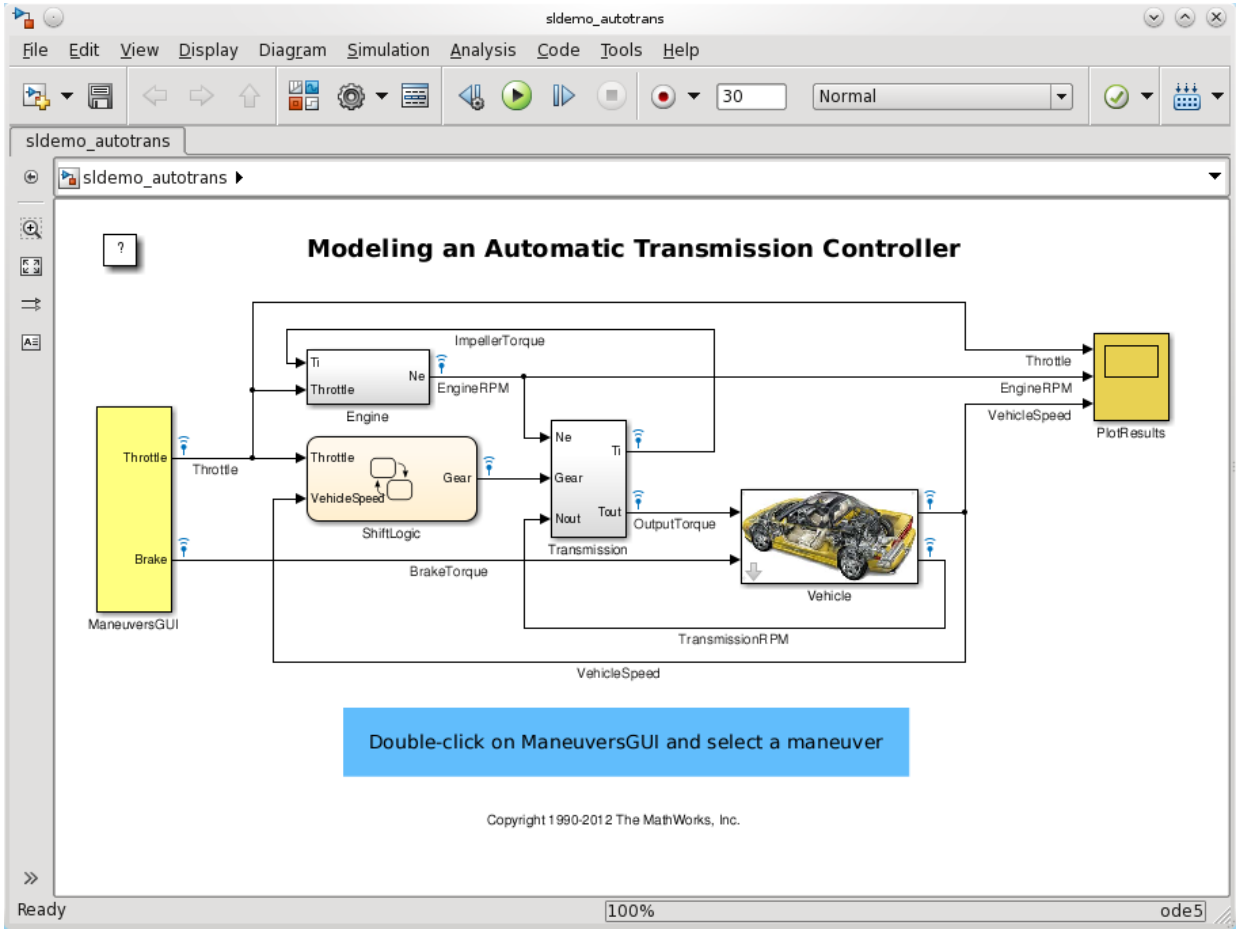
This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files, for use by the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

Save Harness Data to MAT-Files

Before converting the model to be harness-free, capture the test cases in the harness.

For this example, you will modify the model sldemo_autotrans from the **Modeling an Automatic Transmission Controller** example.

Open the example model. In the MATLAB Command Window type `sldemo_autotrans`.



Use MATLAB function slexAutotransRootInportsSaveActiveGroup to save the Signal Builder block data of the active group into a MAT-file. At the command line type `slexAutotransRootInportsSaveActiveGroup('slexAutotransRootInport','ManeuversGU`
This function creates a MAT-file in the current directory with the same name as the active group. The function slexAutotransRootInportsSaveActiveGroup has been provided with this example.

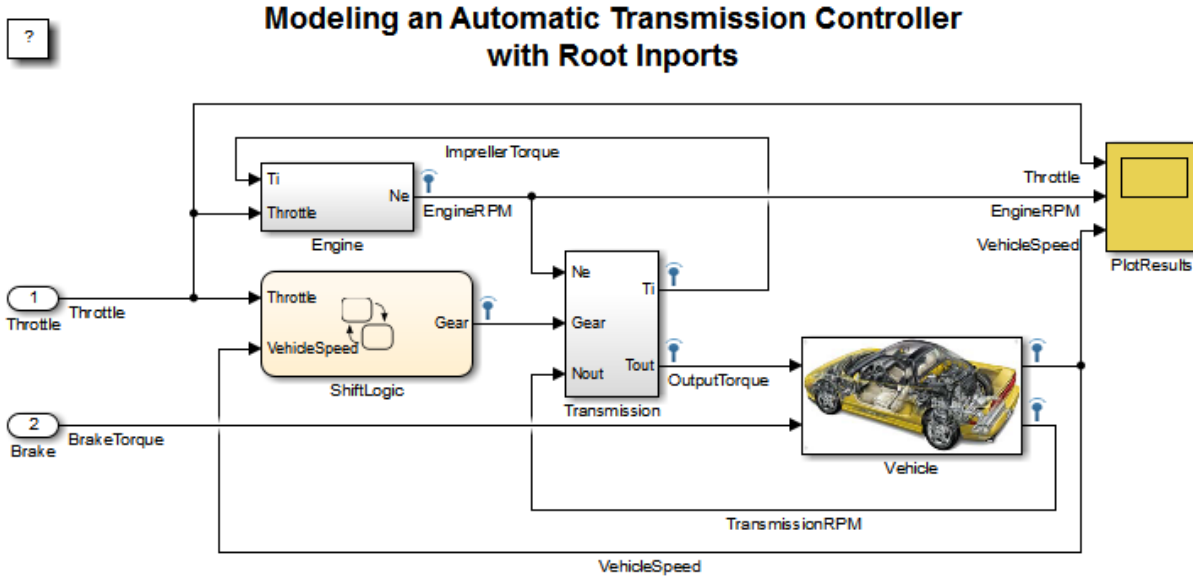
Remove the Signal Builder Block

Remove the Signal Builder block named ManeuversGUI and replace it with two inports.

1. Delete the Signal Builder block named ManeuversGUI.
2. Open the **Simulink Library Browser** and select **Commonly Used Blocks**.
3. Drag and drop two **input ports** from the **Library Browser** to the model.
4. Connect the input ports to the lines previously connected to the Signal Builder block.
5. Rename the inport ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.

Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.



Copyright 2012 - 2014 The MathWorks, Inc.

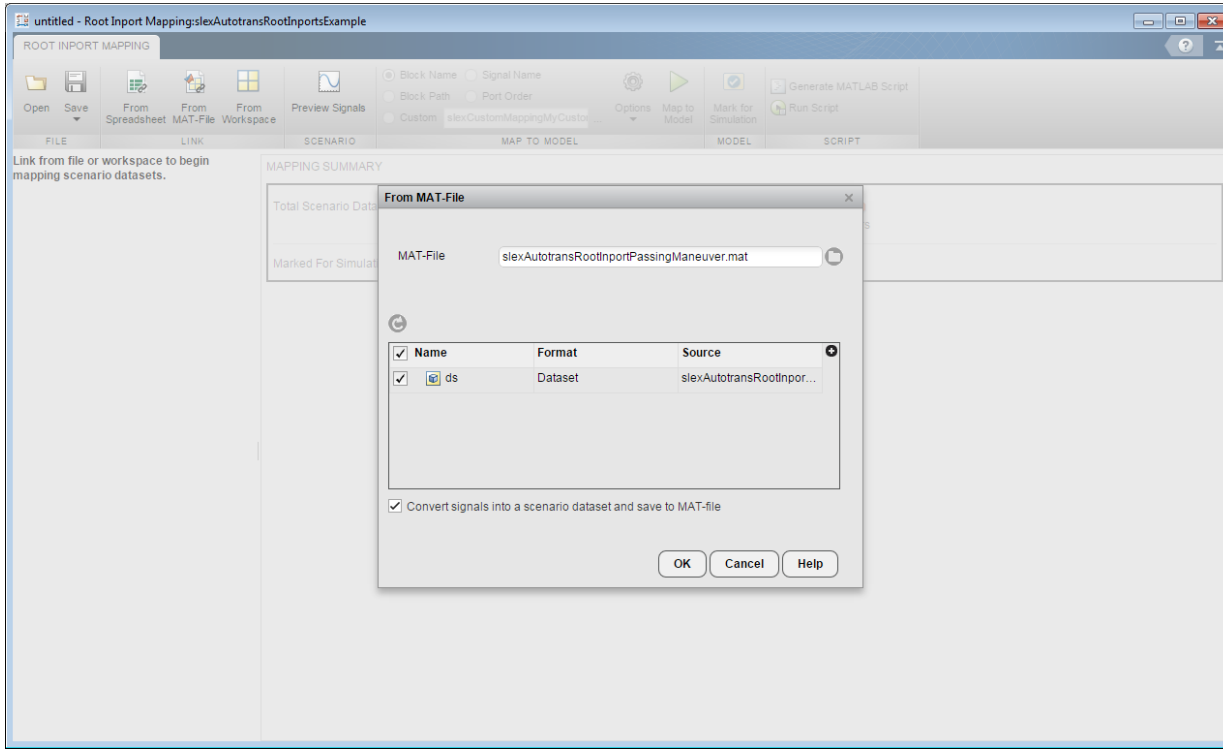
Set Up Harness-Free Inputs

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

From the **Simulation->Model Configuration Parameters->Data Import/Export** pane, click the **Connect Input** button.

Map Signals to Root Inport

The Root Inport Mapping tool opens.



This example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **From MAT-File** button on the Root Inport Mapping toolbar. When the link dialog appears, click the Open Folder button. In the browser, select the MAT-file that you saved earlier.

Select a Mapping Mode

Once you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:

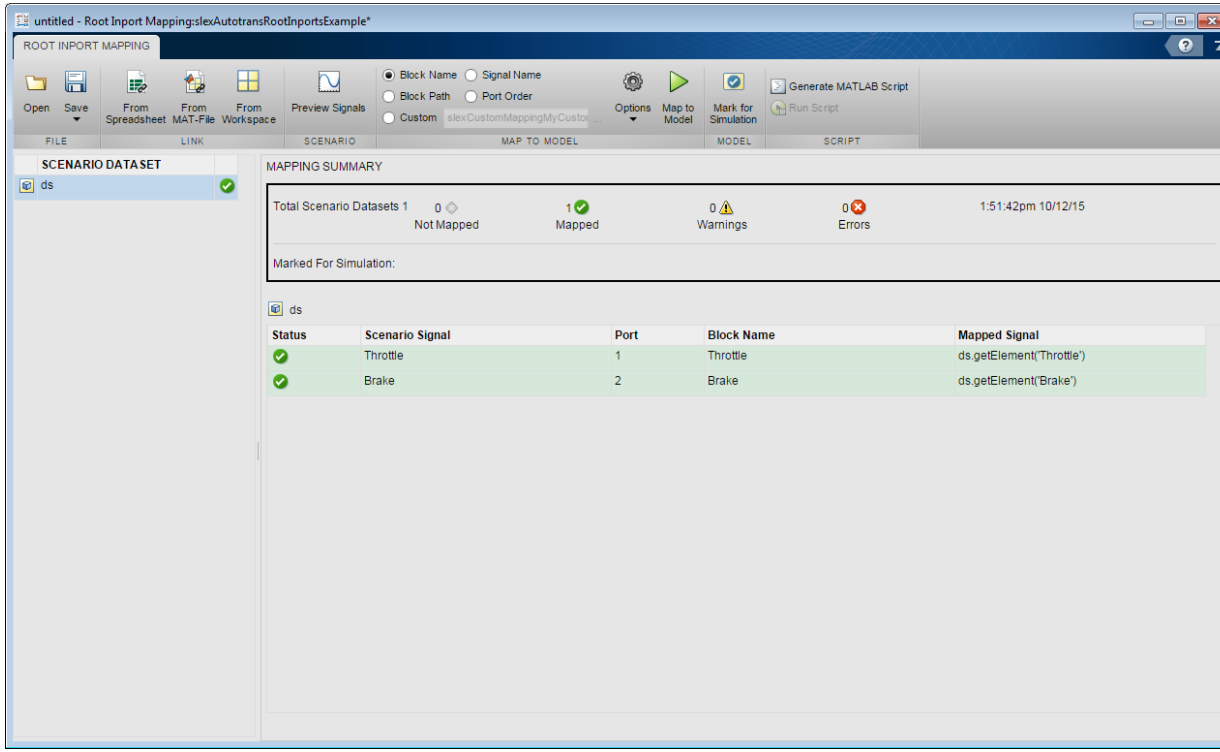
- **Port Order** - Maps in the order it appears in the file to the corresponding port number.
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Earlier in this example, you used the `slexAutotransRootInportsSaveActiveGroup` to save input data to variables of the same name as the harness signals Throttle and Brake, and you added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries try to match input data variable names to the names of the input ports. To select this option:

1. Click the **Block Name** radio button.
2. Click the **Options** button and select Compile from the dropdown. This will provide some verification on the mapping.
3. Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine whether or not there is a compatibility issue. The status of this compatibility is reflected by the table colors green, orange, or red. Clicking a cell in the table which has orange or red color will open the Comparison Tool for further inspection.

- **Data Type** - Double, single, enum, ...
- **Complexity** - Real or complex
- **Dimensions** - Signal dimensions vs port dimensions

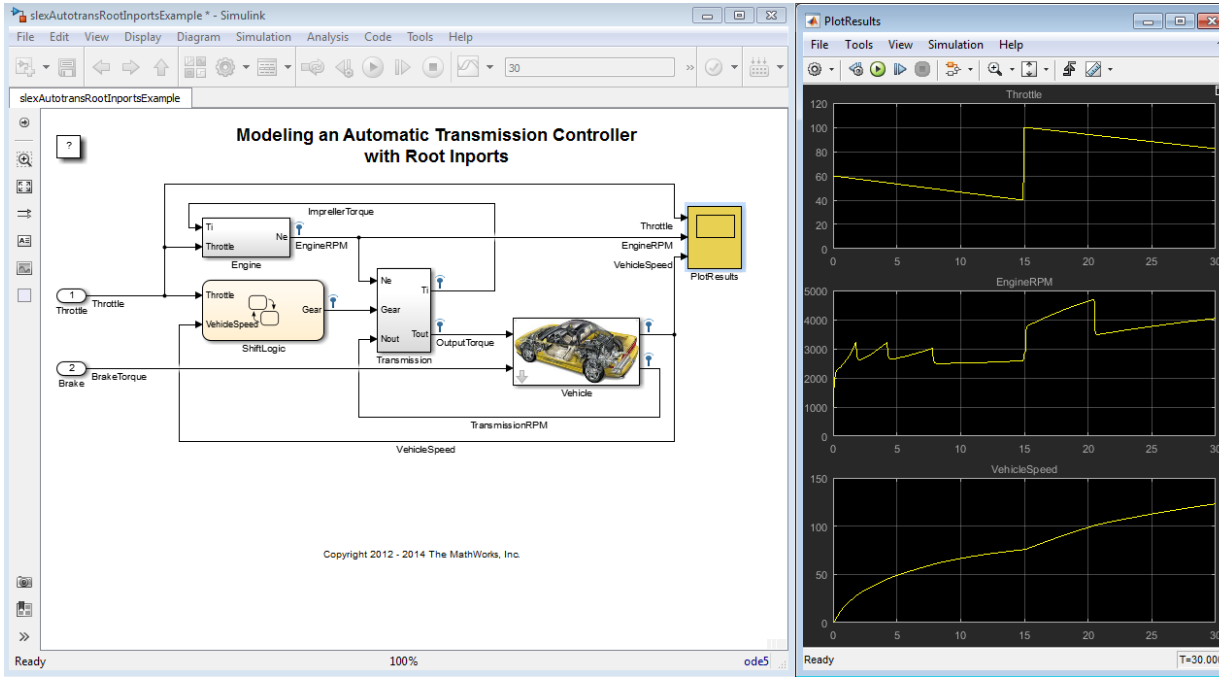


Finalize the Inputs to the Model

Review the results of the mapping compatibility. Click the Scenario Dataset 'ds' in the scenario dataset list. To apply the results of the **Map** action and load the data that was mapped to the input ports from the MAT-file to the base workspace click the **Mark for Simulation** button. This action also sets the **Model Configuration Parameters->Data Import/Export->External Input** edit box with the proper comma-separated list of inputs.

Simulating the Model

With the changes applied you can now simulate the model and view the results. Click the **Play** button on the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.



Alternative Workflows to Load Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands similar to:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:

- Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

Note: The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

```
% Create signal groups
fileName = 'testCase';
for k =1 :3

    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    %create a dataset
    ds = Simulink.SimulationData.Dataset();
    ds = ds.addElement( var1, 'var1');
    ds = ds.addElement( var2, 'var2');
    ds = ds.addElement( var3, 'var3');

    % Save the data
    save([fileName '_' num2str(k) '.mat' ],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
   % Load the MAT-file.
   load([fileName '_' num2str(k) '.mat']);

   % Simulate the model
   simOut{k} = sim('model_name');
end
```

Use the PreLoadFcn Pane

When you are satisfied with the data and mapping, you can configure your model to load to the MATLAB workspace a MAT-file of the same signal group. Call the `load` function in a `PreLoadFcn` callback in the model properties node.

1. After saving the MAT-file, in the Simulink editor, select **File** > **Model Properties** > **Model Properties**.
2. In the Model Properties window, select the `PreLoadFcn` node.
3. Enter a load function that loads the signal data MAT-file. For example,

   ```
   load d_signal_data.mat;
   ```

4. Click **OK** and save the model.

Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see "Root Inport Mapping Scenarios" on page 59-193).

1. Associate your scenario with the model.
2. In the **SCRIPT** section, click **Generate MATLAB Script** and supply a script name when prompted.
3. To run the script, click **Run Script**.
4. To evaluate the results of the simulation, see the base workspace.

More About

- "Root Inport Mapping Scenarios" on page 59-193

Create and Use Custom Map Modes

Create Custom Mapping File Function

If you do not want to use the map modes in the Root Inport Mapping tool, create a custom mapping file function. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

For examples, see these files in the folder *`matlabroot`*`/help/toolbox/simulink/examples` (open).

File	Description
`BlockNameIgnorePrefixMap.m`	Custom mapping file function that ignores the prefix of a signal name when importing signals
`BlockNameIgnorePrefixData.mat`	MAT-file of signal data to be imported
`ex_BlockNameIgnorePrefixExample`	Model file into which you can import and map data

In addition, see the example Using Mapping Modes with Custom-Mapped External Inputs.

To create a custom mapping file function:

1. Create a MATLAB function with these input parameters:
   - Model name
   - Signal names specified as a cell array of strings
   - Signals specified as a cell array of signal data
2. In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
3. Save and close the MATLAB function file.

4 Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

1 Open the model that you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
2 Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.
3 In the **Load from workspace** section, click **Connect Input**.
4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
5 In the **MAP TO MODEL** section of the toolstrip, click **Custom**.
6 In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

   By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for the Attaching Input Data to External Inputs via Custom Input Mappings example.

   Tip The Root Inport Mapping tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.
7 Click **Options** and select the **Compile** check box.
8 Click **Map**.

   The model is compiled and the Root Inport Mapping tool gets updated.

   To understand the mapping results, see "Understand Mapping Results" on page 59-176.
9 Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation. For more information, see "Alternative Workflows to Load Data" on page 59-186.

Custom Mapping Modes Similar to Simulink Modes

If your custom mapping mode is similar to a Simulink mapping mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see Using Mapping Modes with Custom-Mapped External Inputs.

Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter

Root Inport Mapping Scenarios

In this section...
“Open Scenarios” on page 59-193
“Save Scenarios” on page 59-194
“Open Existing Scenarios” on page 59-194
“Work with Multiple Scenarios” on page 59-195

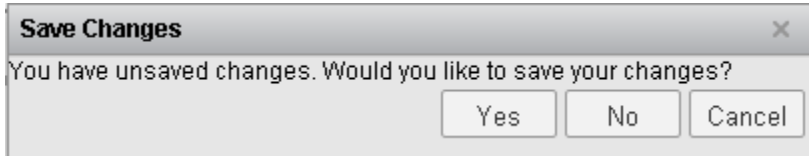
Use the Root Inport Mapping tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapping tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel. Place the signal files in the last known location (where you used the Root Inport Mapping tool most recently) or the MATLAB path.

Open Scenarios

To open an existing scenario, click **Open**. If you are working in another scenario, the Root Inport Mapping tool displays a message.



To...	Click...
Open a new scenario. Remove the existing scenario without saving it.	**No**

To...	Click...
Cancel opening a scenario.	**Cancel**
To save the existing scenario, click **Yes**. Then click the **Open** button again to open an existing scenario.	**Yes**

Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar is has an asterisk (*), you can save a scenario.

1. On the Root Inport Mapping toolbar, select **Save** > **Save As**.
2. In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.

   - To save the signals and the scenario file, click **Yes**.

     If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

1. On the Root Inport Mapping tool toolbar, click **Save**.
2. Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.

   If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

Goal	Action
Overwrite the existing `.mldatx` file.	**Yes**
Exit the dialog box. The tool does not save the scenario.	**No**

Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (*.`mldatx`). The Root Inport Mapping tool opens and loads the model. Alternatively, right-click the file and select **Open**.

  - When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.
  - If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapping tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

Goal	Click
Save the existing scenario and associated data before loading the new scenario.	**Yes**
Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario.	**No**

Work with Multiple Scenarios

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapping tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the `Simulink.SimulationData.Dataset` format:

1. To convert the signals to a `Simulink.SimulationData.Dataset` format, use the `convertToSlDataset` function.
2. Link to the new data set. You do not need to reopen the scenario.

Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block includes units information for `Dataset` or `Timeseries` logging formats.

Logging root-level Outport data from a previous simulation contains units information if:

- These **Data Import/Export** configuration parameter settings:
  - **Output** is enabled.
  - **Format** is `Dataset`.
- For the Outport blocks that you log, in the Block Parameters dialog box, you set the **Unit** parameter.

Otherwise, to include units in signal data that you load, for the `Units` property of the MATLAB `timeseries` objects that you want to load, specify a `Simulink.SimulationData.Unit` object.

Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Outport block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

Load Data Using the From File Block

In this section...
"Data Loading" on page 59-199
"Sample Time" on page 59-200
"Simulation Time Hits Without Corresponding Time Data" on page 59-200
"Duplicate Timestamps" on page 59-200
"Detect Zero Crossings" on page 59-201

To load signal data with a From File block for use in a model:

1. Create a MAT-file with the signal data that you want to load.
2. Add a From File block to a model. Connect the From File block to the block that the From File provides input to.
3. In Block Parameters dialog box of the From File block, configure the block by specifying:
   - The path to the file that you want to load data from
   - The data format for the From File block output
   - How the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection

Data Loading

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory at the start of simulation. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For each simulation time hit for which the MAT-file contains no matching timestamp, Simulink uses interpolation or extrapolation to obtain the needed data. You specify the interpolation and extrapolation methods. For details, see "Simulation Time Hits That Have No Corresponding MAT-File Timestamps."

During simulation, the From File block cannot load data from a MAT-file that a `To File` block is exporting data to.

Sample Time

The From File block **Sample time** parameter specifies the sample time to load data from a MAT-file. The timestamps in the file must be monotonically nondecreasing. For details, see the From File block documentation.

Simulation Time Hits Without Corresponding Time Data

If a simulation time hit does not have a corresponding MAT-file timestamp, then the From File block output depends on:

- Whether the simulation time hit occurs before the first timestamp, within the range of timestamps, or after the last timestamp
- The interpolation or extrapolation methods that you select
- The data type of the MAT-file data

For details about interpolation and extrapolation options, see the descriptions of the following parameters in "Parameters and Dialog Box":

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

Duplicate Timestamps

Sometimes the MAT-file includes duplicate timestamps (two or more data values that have the same timestamp). When that happens, the From File block action depends on when the simulation time hit occurs, relative to the duplicate timestamps in the MAT-file.

Suppose that the MAT-file contains the following data, with three data values having a timestamp value of 2:

```
time stamps:    0 1 2 2 2 3 4
data values:    2 3 6 4 9 1 5
```

The following table describes the From File block output.

Simulation Time, Relative to Duplicate timestamp Values in MAT-File	From File Block Action
Before the duplicate timestamps	Uses the first of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 6.)
At or after the duplicate timestamps	Uses the last of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 9.)

For more information, see the From File block documentation for these parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

Detect Zero Crossings

Zero-crossing detection locates a discontinuity in timestamps, without resorting to excessively small time steps. By default, the From File block does not enable zero-crossing detection.

For the From File block, zero-crossing detection occurs only at timestamps in the file. Simulink examines only the timestamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

For more information, see the From File block documentation of the **Enable zero-crossing detection** parameter.

Load Data Using the From Workspace Block

In this section...
“Specify the Workspace Data” on page 59-202
“Sample Time” on page 59-203
“Interpolate Missing Data Values” on page 59-203
“Specify Output After Final Data” on page 59-203
“Detect Zero Crossings” on page 59-204

To load signal data with a From Workspace block:

1. Create a workspace variable with the signal data that you want to load. See “Create Data for a From Workspace Block” on page 59-138.
2. Add a From Workspace block to a model. Connect the From Workspace block to the block that the From Workspace block provides input to.
3. In the Block Parameters dialog box of the From Workspace block, configure:
   - The workspace data to load
   - The data format for the From Workspace block output
   - How the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection

An alternative to using a From Workspace block for loading workspace data is to load data to a root-level input port. For more information, see “Root-Level Input Ports” on page 59-98.

Specify the Workspace Data

In the dialog box of the From Workspace block, in the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For example, suppose that the workspace contains a column vector of times named `T` and a column vector of corresponding signal values named `U`. Entering the expression `[T U]` for **Data** parameter yields the required input array. If the required array or structure exists in the workspace, enter the name of the structure or matrix in the **Data** parameter.

If you load a structure that does not specify a time vector:

1. Set **Sample time (-1 for inherited)** to a value other than `0` (continuous).
2. Clear **Interpolate data**.
3. Set **Form output after final data value by** to a value other than `Extrapolation`.

For more information, see "Create Data for a From Workspace Block" on page 59-138.

Sample Time

The From Workspace block **Sample time** parameter specifies the sample time to load data from a workspace. The timestamps in the workspace data must be monotonically nondecreasing. For details, see "Specify Sample Time" on page 7-3.

Interpolate Missing Data Values

To use linear Lagrangian interpolation to compute data values for time hits that occur between the time hits for which the workspace supplies the data, select **Interpolate data**.

For variable-size signals, clear **Interpolate data**.

Specify Output After Final Data

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

Iin the From Workspace block documentation, see the **Form output after final data value by** parameter.

Detect Zero Crossings

By default, the From File block does not enable zero-crossing detection.

Zero-crossing detection locates discontinuities, without resorting to excessively small time steps.

The **Enable zero-crossing detection** parameter applies only if the sample time is continuous (0).

If you select the **Enable zero-crossing detection** parameter, and if an input array contains multiple entries for the same time hit, Simulink detects a zero crossing at that time hit.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

Create Dataset Data for Root Inport Ports

In this section...

"Specify a Dataset Using the Input Parameter" on page 59-205
"Dataset Elements" on page 59-205
"Import Dataset Objects for Buses" on page 59-205

Specify a Dataset Using the Input Parameter

You can use a Dataset object as a value for the **Configuration Parameters** > **Data Import/Export** > **Input** parameter. Specify only one `Dataset` object and do not include it in a comma-separated list.

Dataset Elements

A `Dataset` object can include elements with different data types. The elements can be:

- A MATLAB `timeseries` object
- A structure, if each leaf node is either empty or is a MATLAB `timeseries` object
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See "Create Data Arrays for Root-Level Inports" on page 59-209.
  - An `nx1` array for a root inport that drives a function-call subsystem. See "Arrays for Input Ports Driving Function-Call Subsystems" on page 59-210.
- A `Simulink.SimulationData.Signal` object
- An empty matrix

The number of elements in the data set must match the number of root-level input ports.

Import Dataset Objects for Buses

You can use a `Dataset` object to import bus data for a root-level input port. For details, see "Import Bus Data to Top-Level Input Ports" on page 59-147.

Create MATLAB Timeseries Data for Root Inports

In this section...
“Specify Time Dimension” on page 59-207 “Models with Multiple Root Inport Blocks” on page 59-208

A root-level Inport, Enable, Trigger, and From Workspace block can import data specified by a MATLAB `timeseries` object residing in a workspace.

Note: This documentation about importing MATLAB timeseries data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

Specify Time Dimension

When you create a MATLAB `timeseries` object to import data to Simulink, the time dimension depends on the dimension and the type of signal data.

Signal Data Dimension or Type	Time Dimension Alignment	Example of timeseries Constructor

Scalar or a 1D vector	First	Constructor for a scalar signal. Time is aligned with the first dimension.
		`t = (0:10)';`
		`ts = timeseries(sin(t), t);`

2D (including row and column vectors) or greater	Last	Constructor for a matrix signal. Time is aligned with the last dimension.
		`t = 0;`
		`ts = timeseries([1 2; 3 4], t);`

2D row vector, and there is only one time step	Last	`'InterpretSingleRowDataAs3D', true`
		For example:
		`t = 0;`
		`ts = timeseries([1 2], t, 'Interpret`

Models with Multiple Root Inport Blocks

To use a MATLAB `timeseries` object for a root Inport block in a model that has multiple root Inport blocks, convert all the other root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to one of these formats:

- MATLAB `timeseries` objects
- A structure of MATLAB `timeseries` objects

You can use the `Simulink.Timeseries.convertToMATLABTimeseries` method to convert a `Simulink.Timeseries` object to a MATLAB `timeseries` object. For example, if `sim_ts` is a `Simulink.Timeseries` object, then the following line converts `sim_ts` to a MATLAB `timeseries` object:

```
ts = sim_ts.convertToMATLABTimeseries;
```

Create Data Arrays for Root-Level Inports

In this section...
"Data Array Format" on page 59-209
"Specify the Input Expression" on page 59-209
"Arrays for Input Ports Driving Function-Call Subsystems" on page 59-210

Data Array Format

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal driving the trigger port must be the last data item.

The total number of columns of the input matrix must equal `n + 1`, where `n` is the total number of signals entering the model input ports.

Specify the Input Expression

The default input expression for a model is `[t,u]` and the default input format is `Array`. So if you define `t` and `u` in the MATLAB workspace, simply select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to input data from the model workspace.

For example, suppose that you have a model with two Inport blocks:

- The `In1` block accepts two signals (the block has the **Port dimensions** parameter set to `2`).
- The `In2` block accepts one signal (the block uses the default value for the **Port dimensions** parameter).

You define `t` and `u` in the MATLAB workspace:

```
numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t),cos(t),4*cos(t)];
```

When the simulation runs, the signal data `sin(t)` and `cos(t)` are assigned to `In1` and the signal data `4*cos(t)` is assigned to `In2`. Signal data is input for 100 time points.

Note The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and data types other than `double`.

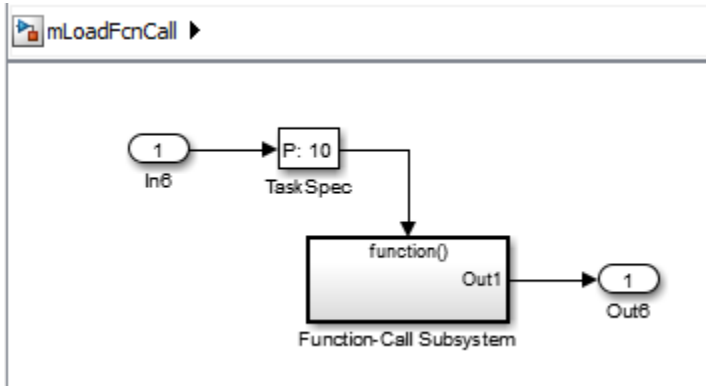
Arrays for Input Ports Driving Function-Call Subsystems

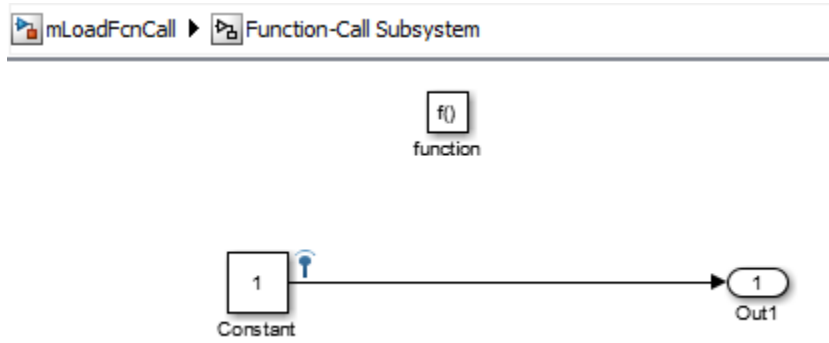
You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a `Dataset` object. The array must be an `nx1` array. For the root-level Inport block, select the **Output function call** parameter.

For example, this `Dataset` object has an array element `x`:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x,'theElementName');
```

This model uses the `ds` data set in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.





When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem shows that the Function-Call Subsystem was triggered only for the times specified in array stored in `ds`.

```
>> logsout.get(1).Values.Time

ans =

     1
     3
     7
     8
```

Create MATLAB Time Expressions for Root Inports

Specify the Input Expression

You can use a MATLAB time expression to import data from a workspace. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. For example, suppose that a model has one vector Inport that accepts two signals. Furthermore, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. The following are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

Create Data Structures for Root Inports

In this section...
“Data Structures” on page 59-214
“Structures for All Ports or for Each Port” on page 59-215
“Specify Signal Data” on page 59-215
“Specify Time Data” on page 59-216
“Examples of Specifying Signal and Time Data” on page 59-217

Data Structures

The Simulink software can load data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters > Data Import/Export > Input** parameter.

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

The structure always includes a signals substructure, which contains a values field and a dimensions field. For details about the signal data, see “Specify Signal Data” on page 59-215. Depending on the modeling task that you want to perform, the structure can also include a time field.

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see “Structures for All Ports or for Each Port” on page 59-215.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For details, see:

- "Import Data to Test a Discrete Algorithm" on page 59-124
- "Import Data to Model a Continuous Plant" on page 59-121
- "Import Data for an Input Test Case" on page 59-126

For both discrete and continuous signals, specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. For details, see "Specify Signal Data" on page 59-215.

For continuous signals, you can specify a `time` field, which contains a time vector. See "Specify Time Data" on page 59-216.

Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one `signals` field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, `in1, in2,..., inN`. The value `in1` is the data for first input port in the model, `in2` for the second input port, and so on.

The rest of the section about importing structure data focuses on specifying one structure for all ports.

Specify Signal Data

Each `signals` substructure must contain two fields: `values` and `dimensions`.

The Values Field

The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions `4-by-5-by-51`.

The Dimensions Field

The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose:

- First element specifies the number of rows in the matrix
- Second element specifies the number of columns

Note Set the **Port dimensions** parameter of the `Inport` or the `Trigger` block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, an error message is displayed when you try to simulate the model.

Specify Time Data

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

Signal Data	Time Data Recommendation
Inport or Trigger block with a discrete sample time	Do not specify a time vector. Simulink loads one signal value at each time step.
Evenly spaced discrete signals	Use an expression in this form: `timeVector = timeStep * [startTime:numSteps-1]'` The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you

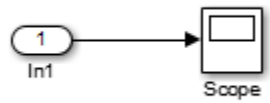
Signal Data	Time Data Recommendation

	want minus 1. For example, to specify 50 time values at 0.2 time steps:
	`T1 = 0.2 * [0:49]'`
	Note: Do *not* use an expression in this form:
	`timeVector = [startTime:timeStep:endTime]'`
	For example, do not use:
	`T2 = [0:0.2:10]'`
	This time vector form is not equivalent to the form that multiplies by time steps (`T1`), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the `T2` form can lead to mismatches between the provided time vector and the times steps taken by Simulink, resulting in unexpected simulation results.

Unevenly spaced values	Use any valid MATLAB array expression; for example, `[1:5 5:10]` or `(1 6 10 15)`. The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.

Examples of Specifying Signal and Time Data

In the first example, consider the following model that has a single input port:

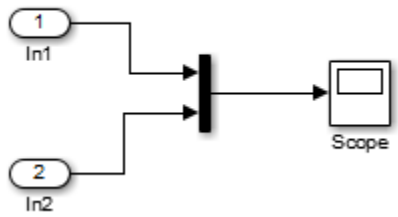


1. Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

   ```
   N = 10
   Ts = 0.1
   a.time = Ts*[0:N]';
   c1 = int8([0:1:10]');
   c2 = int8([0:10:100]');
   a.signals(1).values = [c1 c2];
   a.signals(1).dimensions = 2;
   ```

2. In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
3. In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to `2` and **Data type** to `int8`.

As another example, consider a model that has two inputs:



Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = 0.1*[0:1]';
a.signals(1).values = sin(a.time);
a.signals(1).dimensions = 1;
a.signals(2).values = cos(a.time);
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box.

Note: In this model you do not need to specify the dimension and data type, because the default values are `1` and `double`.

State Information

In this section...
"Simulation State Information" on page 59-220
"Types of State Information" on page 59-220
"Format for State Information Saved Without SimState" on page 59-223
"State Information for Referenced Models" on page 59-224

Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information for calculating the output signal value for the current simulation step.

Some examples of uses of saved state information include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

Types of State Information

You can save these kinds of state information.

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
States for each simulation step	State information of blocks (referred to as partial state data) at each time step of a simulation	**States**
Final state	State information of blocks at the end of the simulation	**Final states**

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
Final state with `SimState`	Final state with a `SimState` object that captures additional internal information that Simulink uses during simulation	**Final States** and **Save complete SimState in final state**

`SimState` provides more complete final simulation state information than final states information by itself does. However, if the requirements and limitations of using `SimState` do not meet your modeling requirements, save final state information without `SimState`.

Comparison of SimState and Final State Logging

Characteristic	Final State	Final State with SimState
Simulation mode	Supports all simulation modes	Normal or Accelerator.
Model reference	"State Information for Referenced Models" on page 59-224	See "Model Referencing" on page 23-43.
Resumed simulation	Not supported	Supported.
Saved state data	Only logged states — the continuous and discrete states of blocks — which are a subset of the complete simulation state of the model User data, run-time parameters, or logs of the model not saved	Complete state information Does not save user data, run-time parameters, or logs of the model.
Block output	User data, run-time parameters, or logs of the model not saved	Simulink tries to save the output of a block as part of a `SimState` even if S-functions declare that no `SimState` states exist in the block. If the block output is of custom type, Simulink displays an error.

Characteristic	Final State	Final State with SimState
Readability	Use structure with time format for best readability	To examine a simplified view of the data, consider using looking at the `loggedStates` property of the Simulink.SimState.ModelSimState class.
Restoring state data	Can save and restore in different simulation modes. If logged state information is not sufficient, you can obtain different results in the two simulation modes.	Cannot save in normal mode and restore in Accelerator, or conversely save in accelerator mode and restore in normal mode.
Restoring multiple states	You can initialize only one out of multiple logged states in the model.	You restore all states in the model. You cannot load a subset of states.
Structural changes	You can make structural changes between simulation and restoring the simulation.	You cannot make structural changes to the model between when you save the `SimState` and when you restore the simulation using the `SimState`. For example, you cannot add or remove a block after saving the `SimState` without repeating the simulation and saving the new `SimState`.
Input to `model` function	To input to model function, use `Array` format with non-complex data of type `double`.	You cannot input the `SimState` to model function.
Code generation	Supported	Not supported

For both `SimState` and final state logging, Simulink saves state information at one of these points:

- At the final time step

- At the execution time at which the simulation paused or stopped

For additional information about `SimState`, see “Limitations of SimState” on page 23-42.

Format for State Information Saved Without SimState

If you do not use the `SimState` for saving state information, then use **Configuration Parameters** > **Data Import/Export** > **Format** to specify the data format for the saved state information.

You can set **Format** to:

- `Dataset` (default)
- `Array`
- `Structure`
- `Structure with time`

The `Array` option for the **Configuration Parameters** > **Data Import/Export** > **Format** option supports compatibility with models developed in earlier releases, when Simulink supported only the array format for saving state information.

The array format reflects the order of signals. The order of saved state information can change between simulations when you change any of the following:

- The model (even without changing the signal)
- The simulation mode
- The code generation mode

The `Structure` and `Structure with time` formats are easier to read and consistent across simulations. Also, these two formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.
- `Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging
- Does not support logging nonvirtual bus data for code generation or rapid accelerator mode.

State Information for Referenced Models

When Simulink saves states in the structure or structure-with-time format, it adds an `inReferencedModel` subfield to the `signals` field of the structure. The value of this additional subfield is true (`1`) if the `signals` field records the final state of a block that resides in the reference model. For example:

```
xout.signals(1)
```

```
ans =

              values: [101x1 double]
          dimensions: 1
               label: 'DSTATE'
           blockName: [1x66 char]
    inReferencedModel: 1
```

If the signals field records a referenced model state, its `blockName` subfield contains a compound path of a top model path and a reference model path. The top model path is the path from the model root to the Model block that references the reference model. The reference model path is the path from the reference model root to the block whose state the `signals` field records. The compound path uses a `|` character to separate the top and reference model paths. For example:

```
>> xout.signals(1).blockName
```

```
ans =

sldemo_mdlref_basic/CounterA|sldemo_mdlref_counter/Previous Output
```

Save State Information

In this section...
“Save State Information for Each Simulation Step” on page 59-226
“Save Partial Final State Information” on page 59-226
“Examine State Information Saved Without the SimState” on page 59-227
“Save Final State Information with SimState” on page 59-228

Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

1. Select the **Configuration Parameters** > **Data Import/Export** > **States** check box.
2. In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
3. Also in the **Data Import/Export** pane, set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`, unless you use array format for compatibility with a legacy model. `Dataset` format does not support code generation or Rapid Accelerator simulation mode.
4. Click **Apply**.
5. Simulate the model.

Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

1. Select the **Configuration Parameters** > **Data Import/Export** > **Final states** check box.
2. In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.
3. Clear the **Save complete SimState in final state** parameter.
4. Set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`.
5. Click **Apply**.

6 Simulate the model.

Examine State Information Saved Without the SimState

If you enable the **Configuration Parameters** > **Data Import/Export** > **Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for States information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

Final State Information in Dataset Format

For example, suppose that you saved final state information in `Dataset` format, and use the default `xFinal` variable for the saved state information.

```
xFinal
```

```
xFinal =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'xFinal'
    Total Elements: 2

  Elements:
    1: 'CSTATE'
    2: 'DSTATE'
```

Examine the first element of the state data set.

```
xFinal.get(1)
```

```
ans =

  Simulink.SimulationData.State
  Package: Simulink.SimulationData

  Properties:
         Name: 'CSTATE'
```

```
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        Label: CSTATE
       Values: [1x1 timeseries]
```

Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
```

```
xFinal =

       time: 20
    signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
```

```
ans =

              values: 2.0108
          dimensions: 1
               label: 'CSTATE'
           blockName: 'vdp/x1'
           stateName: ''
    inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the x1 block is 2.018.

Note: If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

Save Final State Information with SimState

To save complete state information, save the `SimState` for a simulation.

1. Select the **Configuration Parameters > Data Import/Export > Final states** check box.
2. Also in the Data Import/Export pane, select the **Save complete SimState in final state** parameter.
3. In the edit box next to the **Save complete SimState in final state** parameter, enter a variable name for the `SimState` and click **Apply**.
4. Simulate the model.

For more information about using the `SimState`, see “Save and Restore Simulation State as SimState” on page 23-37.

Load State Information

In this section...
“Import Initial States” on page 59-230
“Initialize a State” on page 59-230
“Initialize States in Referenced Models” on page 59-231

Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `SimState`) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters** > **Data Import/Export** parameters to import initial states.

1. Enable the **Initial state** parameter.
2. In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify structure or structure with time data. You cannot specify `Dataset` format data.

Initialize a State

You can initialize a specific state. For example, the following commands create an initial state structure that initializes the `x2` state of the `vdp` model. The `x1` state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the state.

1. Obtain an initial state structure.

```
open_system('vdp');
states = Simulink.BlockDiagram.getInitialState('vdp');
```

2. Set the initial value of the signals structure element associated with `x2` to 2.

   ```
   states.signals(2).values = 2;
   ```

3. Remove the signals structure element associated with `x1`.

   ```
   states.signals(1) = [];
   ```

4. Use the `states` variable for the `vdp` model. Enable the **Configuration Parameters** > **Data Import/Export** > **Initial state** option. Enter `states` in the edit field.

When you simulate the model, both states have the initial value of 2. The initial value of the `x2` state is assigned in the `states` structure, while the initial value of the `x1` state is assigned in its Integrator block.

Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use `SimState`.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

Working with Data Stores

- "Data Store Basics" on page 60-2
- "Model Global Data by Creating Data Stores" on page 60-12
- "Log Data Stores" on page 60-38

Data Store Basics

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

In this section...
"When to Use a Data Store" on page 60-2
"Local and Global Data Stores" on page 60-3
"Data Store Diagnostics" on page 60-3

When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

In some cases, you may be able to use a simpler technique, `Goto` blocks and `From` blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the `Goto` and `From` block reference pages for more information about Goto/From links.

Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only inports and outports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

Local and Global Data Stores

You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data stores only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 60-12.

For information about using referenced models, see “Model Reference”.

Data Store Diagnostics

- “About Data Store Diagnostics” on page 60-3
- “Detecting Access Order Errors” on page 60-4
- “Detecting Multitasking Access Errors” on page 60-6
- “Detecting Duplicate Name Errors” on page 60-8
- “Data Store Diagnostics in the Model Advisor” on page 60-11

About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

Detecting Access Order Errors

- "Data Store Diagnostics and Models Referenced in Accelerator Mode" on page 60-5
- "Data Store Diagnostics and the MATLAB Function Block" on page 60-6

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

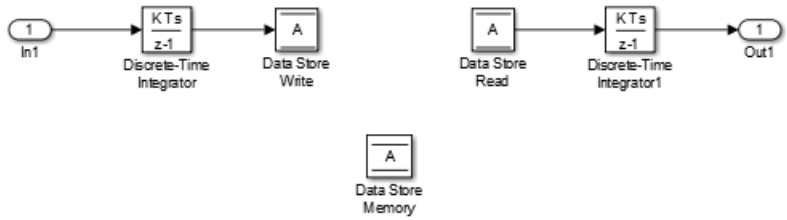
- **Detect read before write:** Detect when a data store is read from before written.
- **Detect write after read:** Detect when a data store is written.
- **Detect write after write:** Detect when a data store is written.

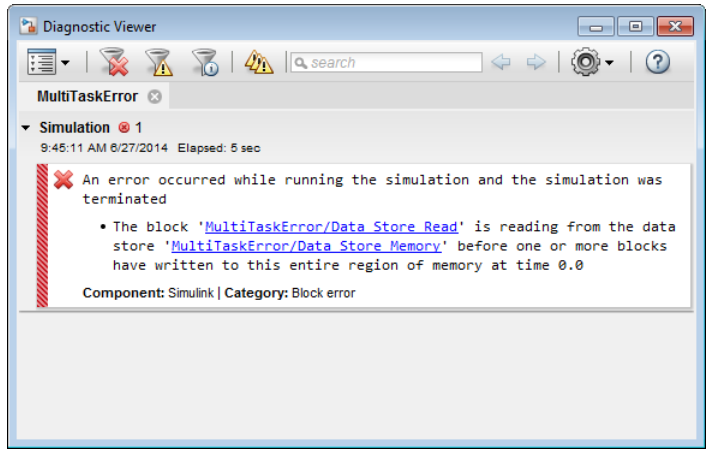
These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block** pane, where each can have one of the following values:

- `Disable all` — Disables this diagnostic for all data stores accessed by the model.
- `Enable all as warnings` — Displays the diagnostic as a warning in the MATLAB Command Window.
- `Enable all as errors` — Halts the simulation and displays the diagnostic in an error dialog box.
- `Use local settings` — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to `none`, `warning`, or `error`. The value specified by an individual block takes effect only if the corresponding configuration parameter is `Use local settings`. See "Diagnostics Pane: Data Validity" and the `Data Store Memory` documentation for more information.

The most conservative technique is to set all data store diagnostics to `Enable all as errors` in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block**. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the `Data Store Read` block to execute before the `Data Store Write` block:





An error occurred during simulation because the data store `A` is read from the `Data Store Read` block before the `Data Store Write` block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to `Use local settings`, then setting that parameter to `none` in the **Diagnostics** pane of the `Data Store Memory` block dialog box. If you use this technique, set the parameter to `error` in all other `Data Store Memory` blocks aside from those that are to be intentionally excluded from the diagnostic.

Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters** > **Diagnostics** > **Data Validity** > **Data Store Memory Block** parameters if you set them to a value other than `Disable all`.

- **Detect read before write** (`ReadBeforeWriteMsg`)

- **Detect write after read** (`WriteAfterReadMsg`)
- **Detect write after write** (`WriteAfterWriteMsg`)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

1. In the Simulink Editor, select **Analysis** > **Model Advisor**.
2. Select **By Task**.
3. Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by `MATLAB Function` blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as `A=foo(A)` might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

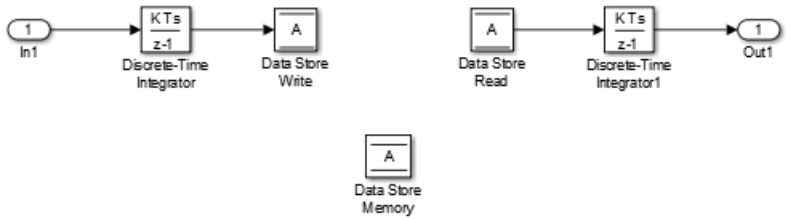
Detecting Multitasking Access Errors

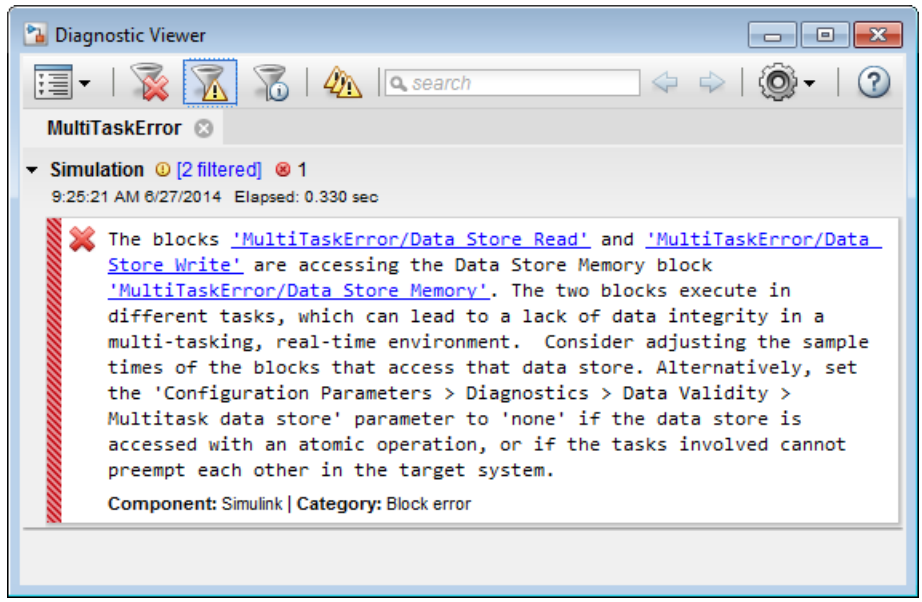
Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

1. A task is writing to a data store.
2. A second task interrupts the first task.
3. The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

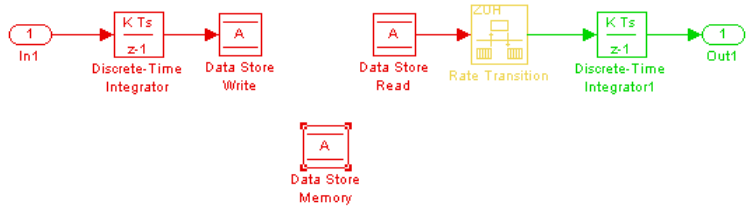
Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block > Multitask Data Store** to `warning` (the default) or `error`. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask Data Store** to `error`:





Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.



With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block > Duplicate Data Store Names** to `warning` or `error`. By default, the value of the diagnostic is `none`, suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate Data Store Names** to `error`:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an

error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

"Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues"

"Check data store block sample times for modeling errors"

"Check if read/write diagnostics are enabled for data store blocks"

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see "Data Store Basics" on page 60-2.

Data Store Examples

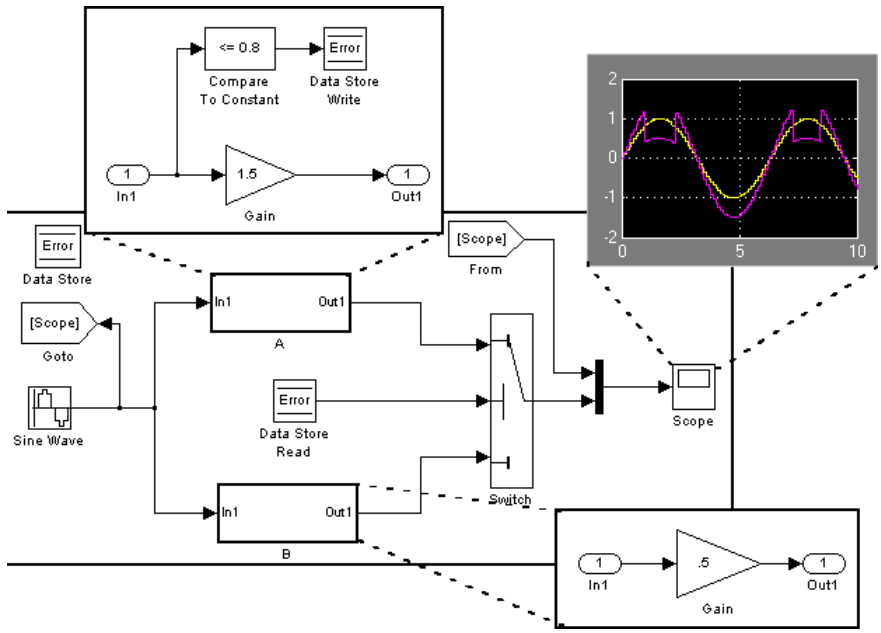
Overview

The following examples illustrate techniques for defining and accessing data stores. See "Order Data Store Access" on page 60-22 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See "Data Store Diagnostics" on page 60-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

Note: In addition to the following examples, see the sldemo_mdlref_dsm model, which shows how to use global data stores to share data among referenced models.

Local Data Store Example

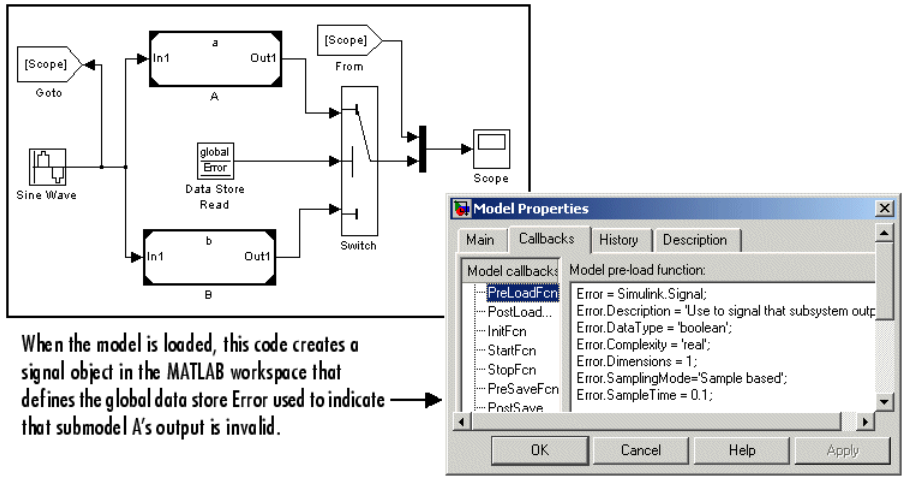
The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.



This model uses a data store to permit subsystem A to signal that its output is invalid. If subsystem A's output is invalid, the model uses the output of subsystem B.

Global Data Store Example

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.



In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace.

Create and Apply Data Stores

Note: To use buses and arrays of buses with data stores, perform *both* the following procedure and "Setting Up a Model to Use Data Stores with Buses and Arrays of Buses" on page 60-30.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

1. Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see "Data Stores and Software Verification" on page 60-2.
2. Create data stores using the techniques described in "Data Stores with Data Store Memory Blocks" on page 60-16 or "Data Stores with Signal Objects" on page 60-19. For greater reliability, consider assigning rather than inheriting data store attributes, as described in "Specifying Data Store Memory Block Attributes" on page 60-16.

3. Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in "Access Data Stores with Simulink Blocks" on page 60-20.
4. Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in "Order Data Store Access" on page 60-22.
5. Apply the techniques described in "Data Store Diagnostics" on page 60-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
6. If you intend to generate code for your model, see "Data Stores in Generated Code" in the Simulink Coder documentation.

To create a data store, you create a `Data Store Memory` block or a `Simulink.Signal` object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A `Data Store Memory` block implements a local data store. See "Data Stores with Data Store Memory Blocks" on page 60-16.
- A `Simulink.Signal` object can act as a local or global data store. See "Data Stores with Signal Objects" on page 60-19.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with `Simulink.Signal` objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with `Simulink.Signal` objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

Data Stores with Data Store Memory Blocks

- "Creating the Data Store" on page 60-16
- "Specifying Data Store Memory Block Attributes" on page 60-16

Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters dialog box to define the data store's properties. The **Data store name** property specifies the name to of the data store that the Data Store Write and Data Store Read blocks access. See `Data Store Memory` documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See "Specifying Attributes Using a Signal Object" on page 60-17 for details.

Specifying Data Store Memory Block Attributes

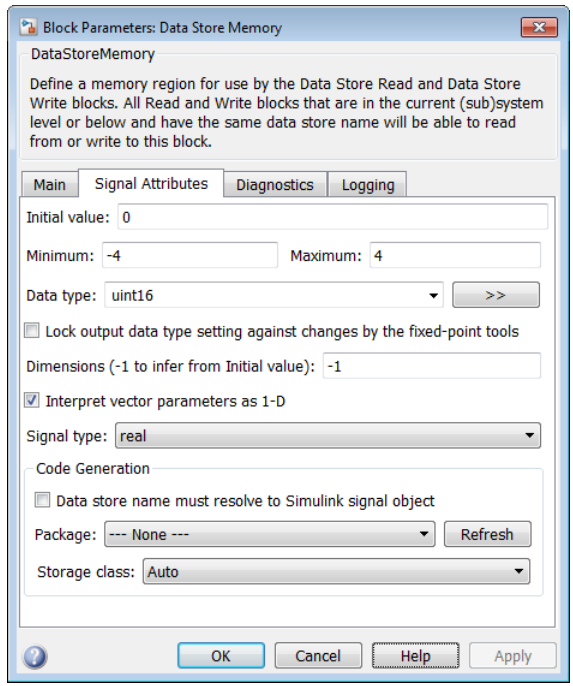
A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box to specify the data type and complexity of a data store. In the next figure, the dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.



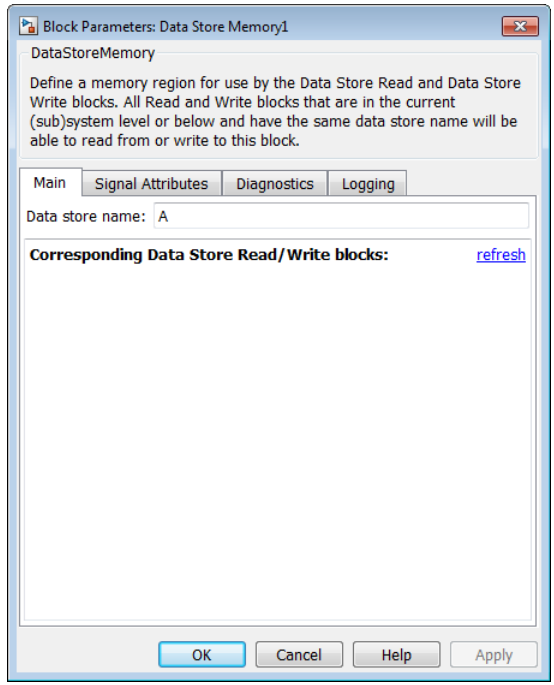
Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

Tip To establish an implicit data store, as described in "Data Stores with Signal Objects" on page 60-19, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

The next figure shows a Data Store Memory block that specifies resolution to a `Simulink.Signal` object, named A. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal**

Attributes tab and select the **Data store name must resolve to Simulink signal object** parameter.



The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the `Simulink.Signal` object `A` has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

```
A =

Simulink.Signal (handle)
         CoderInfo: [1x1 Simulink.CoderInfo]
       Description: ''
          DataType: 'auto'
               Min: []
               Max: []
              Unit: ''
        Dimensions: 1
    DimensionsMode: 'auto'
```

```
    Complexity: 'auto'
    SampleTime: -1
  InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 60-19.

Data Stores with Signal Objects

- “Creating the Data Store” on page 60-19
- “Local and Global Data Stores” on page 60-19
- “Signal Object Attributes for Data Stores” on page 60-19

Creating the Data Store

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

Local and Global Data Stores

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

Signal Object Attributes for Data Stores

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The parameter values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```
Error = Simulink.Signal;
Error.Description = 'Use to signal that subsystem output is invalid';
Error.DataType = 'boolean';
Error.Complexity = 'real';
Error.Dimensions = 1;
Error.SampleTime = 0.1;
```

Attributes for Local Data Stores

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- `DataType`
- `Complexity`
- `SampleTime`

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

Attributes for Global Data Stores

The following table describes the parameter requirements for global data stores.

Parameter	Global Data Store Value
`DataType`	Must be set explicitly
`Complexity`	Must be set explicitly
`Dimensions`	Can be set or inherited
`SampleTime`	Can be set or inherited

Access Data Stores with Simulink Blocks

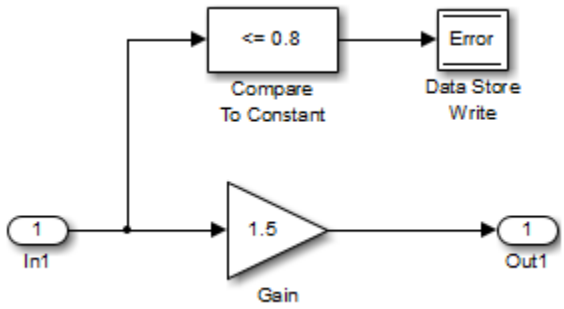
- "Writing to a Data Store" on page 60-21

- "Reading from a Data Store" on page 60-21
- "Accessing a Global Data Store" on page 60-22

Writing to a Data Store

To set the value of a data store at each time step:

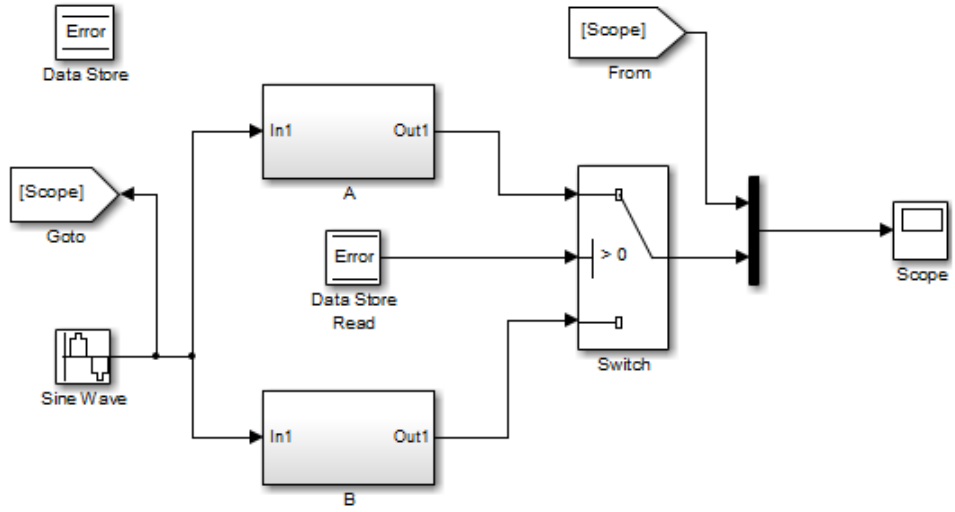
1. Create an instance of a `Data Store Write` block at the level of your model that computes the value.
2. Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.
3. Connect the output of the block that computes the value to the input of the Data Store Write block.



Reading from a Data Store

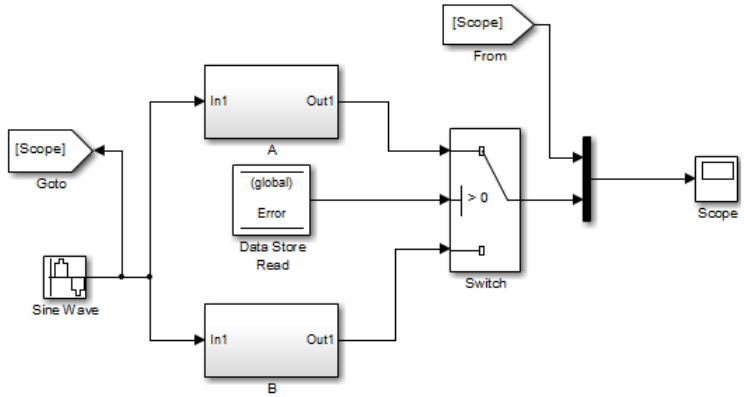
To get the value of a data store at each time step:

1. Create an instance of a `Data Store Read` block at the level of your model that needs the value.
2. Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.
3. Connect the output of the Data Store Read block to the input of the block that needs the data store value.



Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.



Order Data Store Access

• “About Data Store Access Order” on page 60-23

- "Ordering Access Using Function Call Subsystems" on page 60-23
- "Ordering Access Using Block Priorities" on page 60-27

About Data Store Access Order

To obtain correct results from data stores, you must control the order of execution of the data store's reads and writes. If a data store's read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

This section describes several strategies for explicitly controlling the order of execution of a data store's reads and writes. See "Data Store Diagnostics" on page 60-3 for techniques you can use to detect and correct potential data store errors without running simulations.

Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

The subsystem `Before` contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem `After`, which contains the Data Store Read.

Ordering Access Using Block Priorities

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority then `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals
- Frame-based signals

Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a `Simulink.Signal` object. Before performing the procedure, you must understand how to use data stores in a model, as described in "Create and Apply Data Stores" on page 60-14.

To use buses and arrays of buses with data stores:

1. Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see "Manage Bus Objects with the Bus Editor" on page 63-33.
2. Add a data store (using a `Data Store Memory` block or a `Simulink.Signal` object) for storing the bus data.
3. Specify the bus object as the data type of the data store. For details, see "Specify a Bus Object Data Type" on page 57-50.
4. In the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the **Mux blocks used to create bus** diagnostic to `error`. For details, see "Prevent Bus and Mux Mixtures" on page 63-123.
5. If you use a MATLAB structure for the initial value of the data store, then set **Configuration Parameters > All Parameters > Underspecified initialization detection** to `Simplified`. For details, see "Specify Initial Conditions for Bus Signals" on page 63-78 and "Underspecified initialization detection".
6. (Optional) Select individual bus elements to write to or read from a data store. For details, see "Accessing Specific Bus and Matrix Elements" on page 60-30.

Accessing Specific Bus and Matrix Elements

Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the `Data Store Write` block and the **Element Selection** pane of the `Data Store Read` block . Selecting specific bus or matrix elements offers the following benefits:

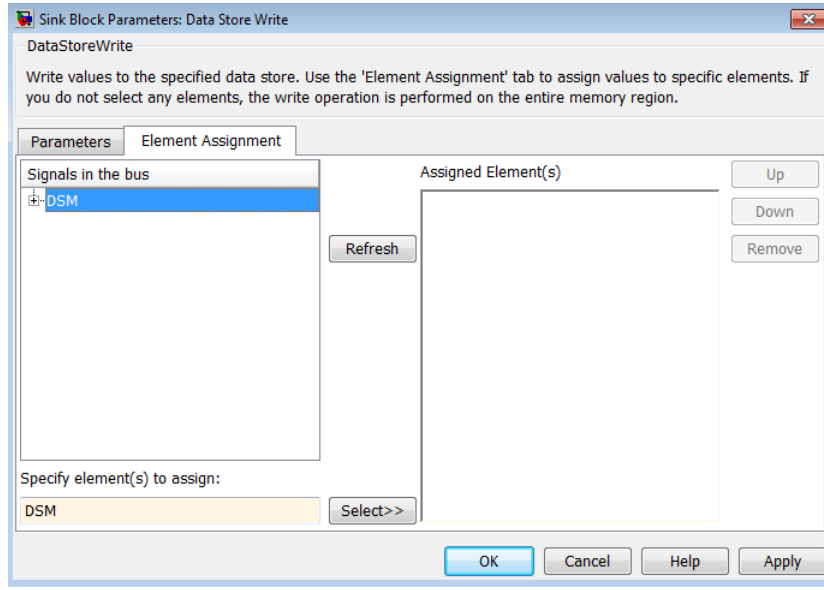
- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

Writing Specific Elements to a Data Store

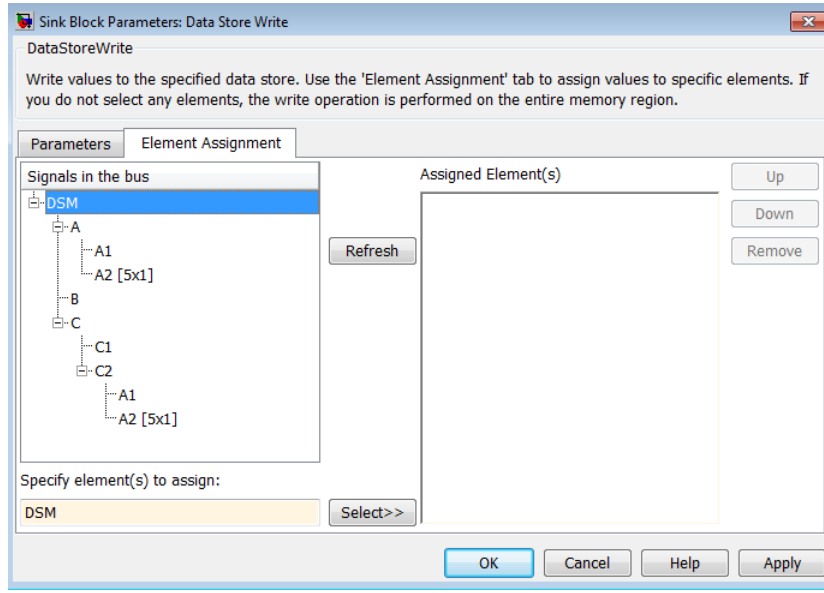
Note: The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see "Specification using the command line" on page 60-35.

To assign specific bus or matrix elements to write to a data store:

1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named `DSM`:

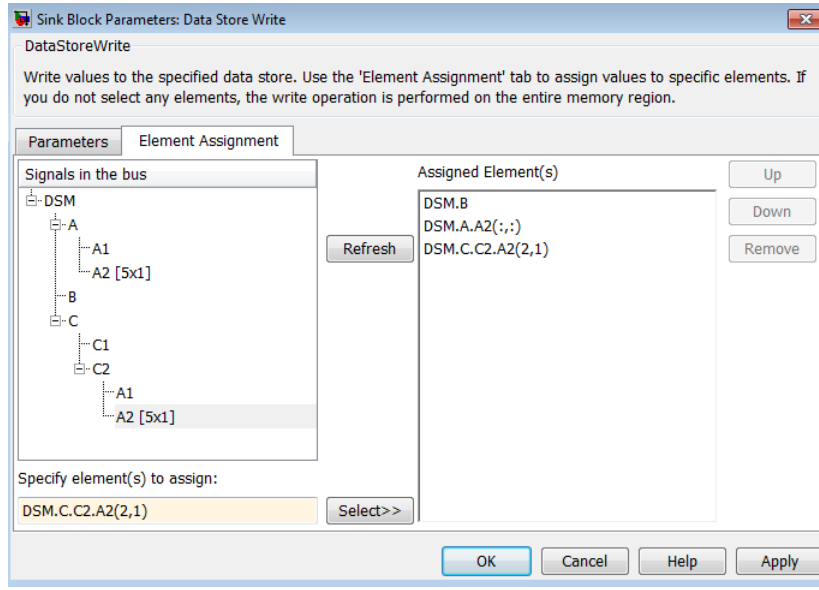


2 Expand all the elements in the **Signals in the bus** list.



3 Specify the elements that you want to write to the data store. For example:

- In the **Signals in the bus** list, click `B`. Then click **Select>>** to select the element `B`.
- To write all the elements of `A2` (in the `A` subbus), select `A2[5x1]`. Then click **Select>>**.
- To write the second element of `A2` in the `C2` subbus, select the `A2[5x1]` element. In the **Specify element(s) to assign** text box, edit the text to say `DSM.C.C2.A2(2,1)`.



For more examples, see “Specifying Elements to Assign or Select” on page 60-34.

4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.

- To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
- To remove an assigned element, click **Remove**.

5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 60-31. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

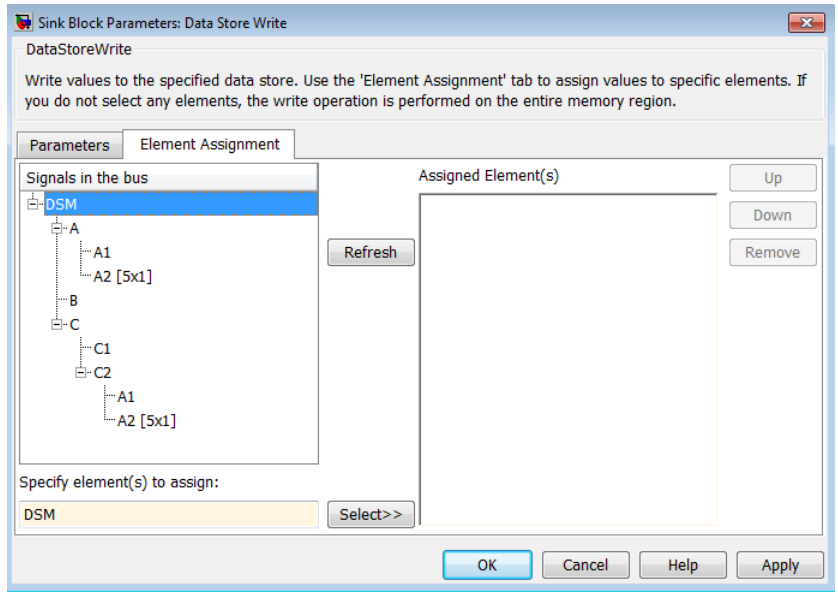
Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see "Creating and Concatenating Matrices".

Note: To select matrix elements, you cannot use dynamic indexing with the **Element Assignment** and **Element Selection** panes of Data Store Read and Bus Assignment block pairs or Data Store Write and Bus Selector block pairs. You can, however, use a `MATLAB Function` block for dynamic indexing.

Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the A2 subbus of the A bus, as shown in the bus hierarchy used in "Writing Specific Elements to a Data Store" on page 60-31.



Valid Syntax	Description
`DSM.A.A2(:,:)`	Selects all elements in every dimension
`DSM.A.A2([1,3,5],1)`	Selects the first, third, and fifth elements
`DSM.A.A2(2:5,1)`	Selects the second through the fifth element

Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the `A2` subbus of the `A` bus, as shown in the bus hierarchy used in "Writing Specific Elements to a Data Store" on page 60-31.

Invalid Syntax	Reason the Syntax Is Invalid
`DSM.A.A2(:)`	You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.
`DSM.A.A2(2:end,1)`	You cannot use the `end` operator.
`DSM.A.A2(idx,1)`	You cannot use variables to specify indices. Consider using a `MATLAB Function` block.
`DSM.A.A2(-1,1)`	The dimension –1 is not within the valid dimension bounds.

Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (#) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

Rename Data Stores

- "Rename Data Store Defined by Block" on page 60-36
- "Rename Data Store Defined by Signal Object" on page 60-36

Rename Data Store Defined by Block

Rename a data store everywhere it is used by `Data Store Read` and `Data Store Write` blocks in a model.

1. In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
2. In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**

Note: You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see "Rename Data Store Defined by Signal Object" on page 60-36.

Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by `Data Store Read` and `Data Store Write` blocks in a model or in a model reference hierarchy.

1. Open the model `sldemo_mdlref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
2. Open Model Explorer.
3. In the **Model Hierarchy** pane, select the base workspace.
4. In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.
5. In the **Select a system** dialog box, click the name of the model `sldemo_mdlref_dsm` to select it as the context for renaming the data store `ErrorCond`.
6. Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

   The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

Customized Data Store Access Functions in Generated Code

Embedded Coder provides a custom storage class that you can use to specify customized data store access functions in generated code. See "Control Data Representation by Applying Custom Storage Classes" and "Access Data Through Functions with Custom Storage Class GetSet".

Log Data Stores

In this section...
"Logging Local and Global Data Store Values" on page 60-38
"Supported Data Types, Dimensions, and Complexity for Logging Data Stores" on page 60-38
"Data Store Logging Limitations" on page 60-38
"Logging Data Stores Created with a Data Store Memory Block" on page 60-39
"Logging Icon for the Data Store Memory Block" on page 60-39
"Logging Data Stores Created with a Simulink.Signal Object" on page 60-40
"Accessing Data Store Logging Data" on page 60-40

Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging – view the order of all data store writes
- Confirming a model modification – use the logged data to establish a baseline for comparing results for identifying the impact of a model modification

To see an example of logging a global data store, see the sldemo_mdlref_dsm model.

Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
  - Simulate the top-level model in Normal mode.
  - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- If you set the **Model Configuration Parameters > Solver > Tasking mode for periodic sample times** parameter to `MultiTasking`, then you cannot log Data Store Memory blocks that use asynchronous sample times or hybrid sample times (that is, sample times resulting from when different data sources for the data store have different sample times).

  For details about viewing information about sample times, see "View Sample Time Information" on page 7-9.
- You cannot log data stores that use custom data types.

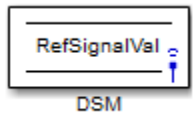
Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

1. In the Block Parameters dialog box for the Data Store Memory block that you want to log, select the **Logging** pane.
2. Select the **Log signal data** check box.
3. Optionally, specify limits for the amount of data logged, using the **Minimum** and **Maximum** parameters.
4. Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
5. Simulate the model.

Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.



Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See "Data Stores with Signal Objects" on page 60-19 for details.

To log a data store that you create with a `Simulink.Signal` object:

1. Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in "Data Stores with Signal Objects" on page 60-19.
2. Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.
3. From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to `1`.

   For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

   ```
   DataStoreSignalObject.LoggingInfo.DataLogging = 1
   ```
4. Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.
5. Enable data store logging with the **Model Configuration Parameters** > **Data Import/Export** > **Data stores** parameter.
6. Simulate the model.

Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

Class	Description
`Simulink.SimulationData.BlockPath`	Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy
Simulink.SimulationData.Dataset	Stores logged data elements and provides searching capabilities; use to group `Simulink.SimulationData.Element` objects in a single object
`Simulink.SimulationData.DataStoreMemor`	Stores logging information from a data store during simulation

You can also convert data logged in formats other than Dataset. For more information, see "Dataset Conversion for Logged Data" on page 59-20.

Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The sldemo_mdlref_dsm model illustrates approaches for viewing data store logging data.

Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
                Name: 'RefSignalVal'
           Blockpath: [1x1 Simulink.SimulationData.BlockPath]
               Scope: 'local'
  DSMWriterBlockPaths: [1x2 Simulink1.SimulationData.BlockPath]
          DSMWriters: [101x1 uint32]
              Values: 101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation.

In this section...
"Dictionary Capabilities" on page 61-2
"Sections of a Dictionary" on page 61-3
"Manage and Edit Entries in a Dictionary" on page 61-4
"Dictionary Referencing" on page 61-4
"Import and Export File Formats" on page 61-4

Dictionary Capabilities

Dictionary Capability	Benefit
Dictionary as data source	All entries in a dictionary are persistent. You do not need to reload data during development.
Explicit data-model linkage	You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves design data from the data dictionary.
Change tracking	When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes.
Entry comparison	Compare values of entries in two dictionaries.
Data grouping into reference dictionaries	Partition and organize data items into reference dictionaries.
Model-data dependency	Discover how entries are used in the model.

Dictionary Capability	Benefit
Store and partition reference data	Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.
Unified interface for defining data	Use the Model Explorer to work with design data in a dictionary.
Incremental update in memory	Improved performance and scalability with minimal footprint on memory.
Requirements traceability linking	Navigate from a data dictionary entry to a location in a requirements document.

Sections of a Dictionary

A Simulink data dictionary is made up of three parts called sections.

1. **Design Data**: Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

   This section can store only certain classes and data types. See "Valid Design Data Classes" on page 61-10 for more information.

2. **Configurations**: Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

   When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see "About Configuration References" on page 13-28.

   This section can also store variant configuration objects, which belong to the Simulink.VariantConfigurationData class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

3. **Other Data**: Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as

data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 61-11 for more information.

Manage and Edit Entries in a Dictionary

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Workspace Variables in Model Explorer” on page 12-51 and “View and Revert Changes to Dictionary Data” on page 61-26.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 61-51.

Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 61-33 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 61-36.

Import and Export File Formats

File Format	Import to Dictionary	Export from Dictionary
MAT-file	✓	✓
MATLAB script	✓	✓

Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

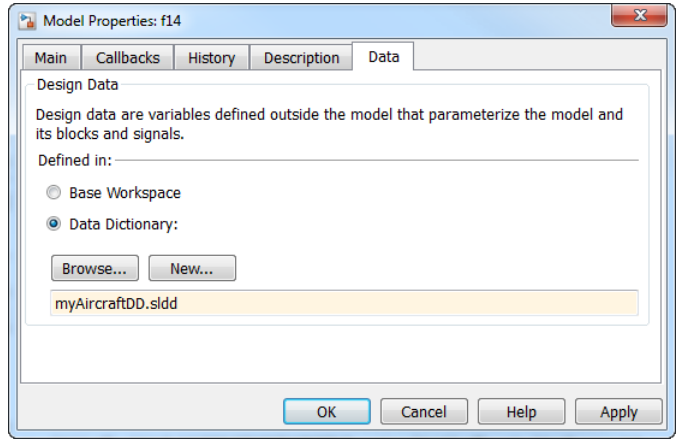
In this section...
“Migrate Single Model to Use Dictionary” on page 61-5
“Migrate Model Reference Hierarchy to Use Dictionary” on page 61-7
“Considerations before Migrating to Data Dictionary” on page 61-8

Migrate Single Model to Use Dictionary

This example shows how to link a single standalone model to a single data dictionary.

Note: Simulink does not import simulation data such as Timeseries objects into the data dictionary.

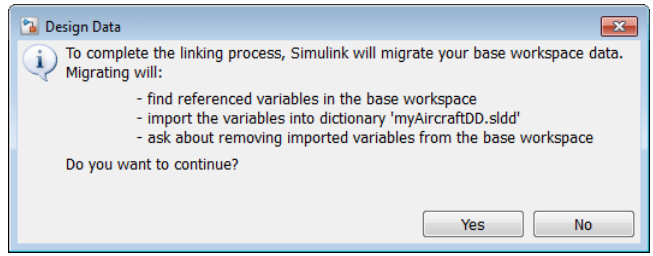
1. Open the `f14` model, which loads design data into the base workspace.
2. In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
3. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



4 Name the data dictionary, save it, and click **Apply**.

5 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.

6 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



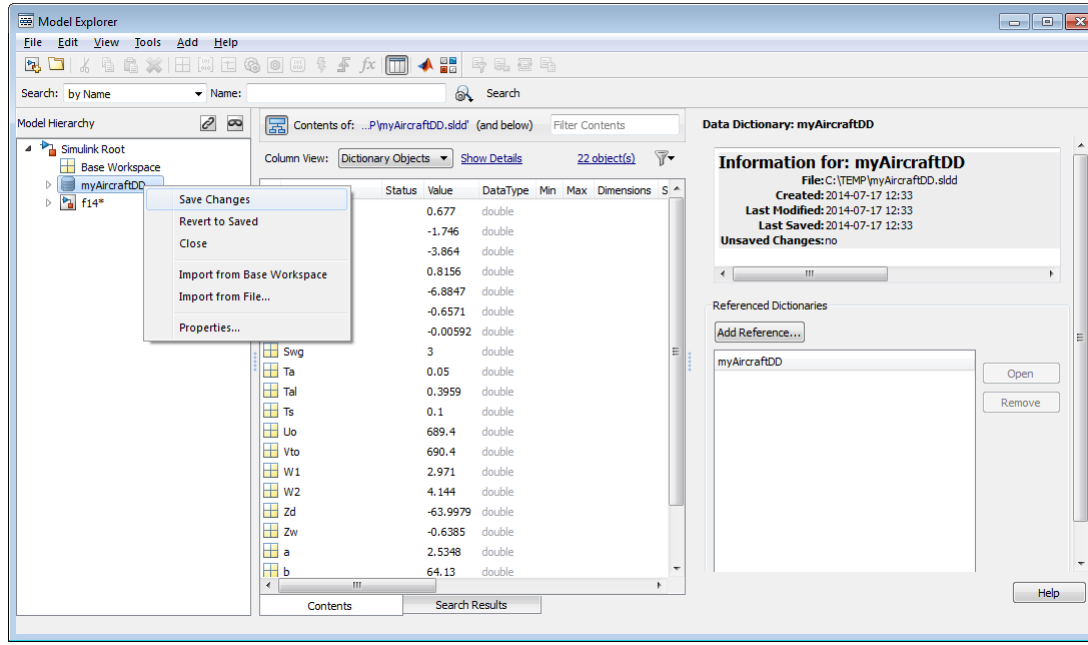
A message appears, reporting the number of items imported from the base workspace to the data dictionary.

7 Click **OK** in the **Model Properties** dialog box.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

8 In the Simulink Editor, click the data dictionary badge in the bottom left corner to open the dictionary.

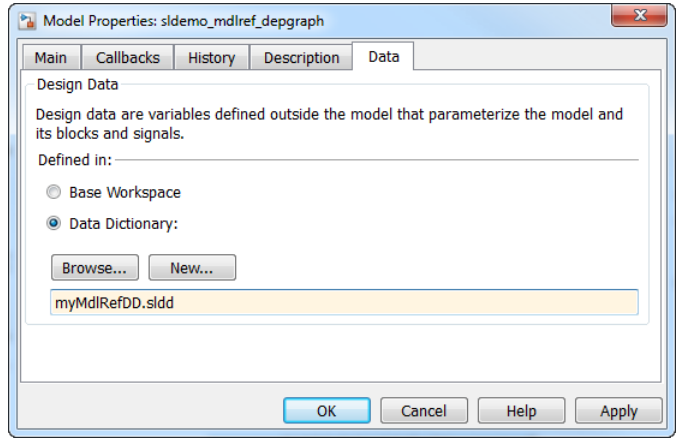
9 Right-click the dictionary node and select **Save Changes**.



Migrate Model Reference Hierarchy to Use Dictionary

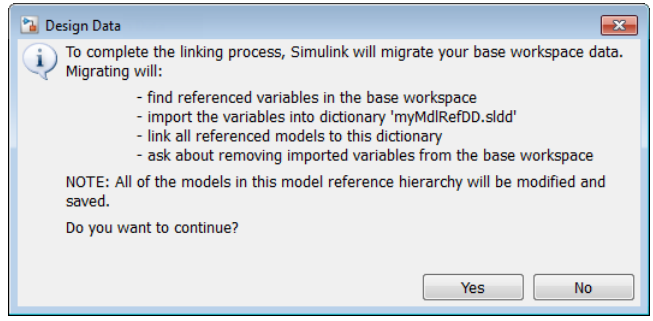
This example shows how to link a parent model and all its referenced models to a single data dictionary.

1. Open the top model containing the model reference hierarchy.
2. In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
3. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



4 Name the data dictionary, save it, and click **Apply**.

5 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



A message appears, reporting the number of items imported to the data dictionary.

Considerations before Migrating to Data Dictionary

- "Check for Data-Loading Callbacks" on page 61-9
- "Check Scripts" on page 61-9
- "Check Tunable Parameters for Code Generation" on page 61-10
- "Data Shared by Model References" on page 61-10
- "Valid Design Data Classes" on page 61-10
- "Invalid Other Data Classes" on page 61-11

• "Data Dictionary Limitations" on page 61-12

Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Simulink Manifest Tools to find data-loading callbacks. See "Analyze Model Dependencies" on page 18-20.

Check Scripts

If you make explicit references to the base workspace by using the handle `base` in your scripts, consider changing these references. When you move any of your data to a data dictionary, the model no longer looks into the base workspace to find design data.

After you migrate design data to a data dictionary, explicit references to the base workspace cannot resolve and errors can occur.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
 enable = 'Enabled';
else
 enable = 'Disabled';
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalinGlobal(myExampleModel,...
'sensor.noiseEnable')
 enable = 'Enabled';
else
 enable = 'Disabled';
```

```
end
```

The `Simulink.data.evalinGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

Check Tunable Parameters for Code Generation

- If your model is linked to a data dictionary, Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.
- If you use the Simulink interface to migrate a model to use a data dictionary, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.
- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.
- If you set the `DataDictionary` property of a model from the command line, convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

Data Shared by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.

The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries. For more information, see “Determine Where to Store Data for Simulink Models” on page 57-78.

Valid Design Data Classes

You can import, store, or create design data objects of the following data classes in the **Design Data** section of a Simulink data dictionary.

- `Simulink.AliasType`

- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.Signal`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`
- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary.

- `Simulink.ConfigSet`
- Simulink.VariantConfigurationData

Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- `timeseries`
- Function handles
- `embedded.numerictype`
- Sparse matrices
- `Simulink.ConfigSetRef`
- Arrays of objects created from built-in or custom classes
- Classes in the `Simulink` or `MATLAB` packages that the Design Data and Configurations sections do not accept
- Custom classes that have a property with any of these names:
  - `LastModified`
  - `LastModifiedBy`
  - `DataSource`
  - `Status`

- `Variant`

Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as `meta` class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow **Explicit and Implicit** signal resolution for a model linked to a data dictionary. The **Signal Resolution** parameter of the model is specified in **Model Configuration Parameters** > **Diagnostics** > **Data Validity**. To use a data dictionary, set **Signal Resolution** to **Explicit only**.
- The data dictionary does not support models that contain `From Workspace` blocks. Further, Simulink does not import simulation data such as `timeseries` objects into the Design Data section of a data dictionary. You can migrate such models in one of the following ways.
  - Before migration, replace `From Workspace` blocks in your model with other source blocks or a combination of source blocks.
  - Migrate the model without replacing `From Workspace` blocks. After migration, replace the `From Workspace` blocks.
- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

  In other words, migrate a model to use a data dictionary before protecting it.

Enumerations in Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

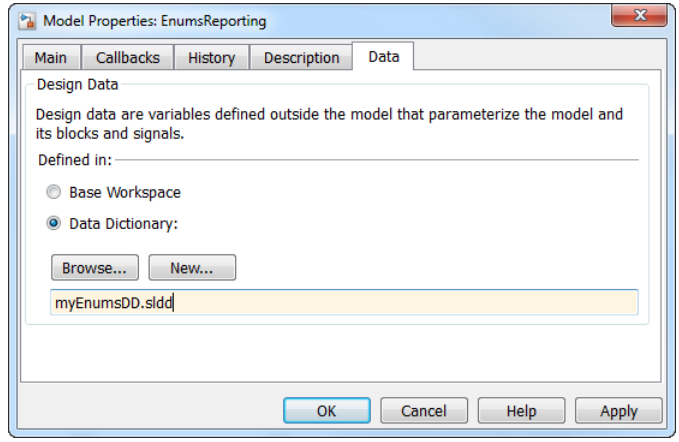
In this section...
“Migrate Enumerated Types into Data Dictionary” on page 61-13
“Manipulate Enumerations in Data Dictionary” on page 61-17

Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

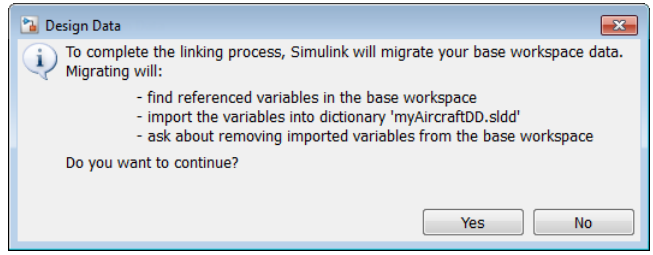
Import Design Data

1. Open a model that uses enumerated types for design data or for blocks in the model.
2. In the Simulink Editor, click **File** > **Model Properties** > **Link to Data Dictionary**.
3. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



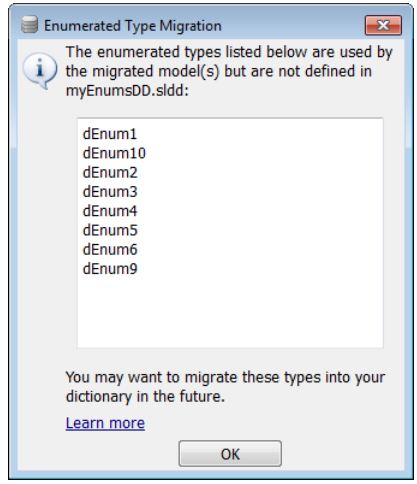
4. Name the data dictionary, save it, and click **Apply**.
5. Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.

6 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



A message appears, reporting the number of items imported from the base workspace to the data dictionary.

7 Simulink reports the enumerated types that were not imported into the data dictionary.



8 Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary,

Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting','IncludeEnumTypes',true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
enumTypesFile = strcmp({usedTypesVars.SourceType},'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType},'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'
```

```
enumTypeNames =

    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'
```

2 Open the data dictionary, and represent it with a `Simulink.data.Dictionary` object.

```
ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')
```

```
ddConnection =

  Dictionary with properties:

          DataSources: {0x1 cell}
```

```
    HasUnsavedChanges: 0
           NumberOfEntries: 3
```

3 Import the enumerated types that are used by blocks in the model.

```
[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection,enumTypeNames)

successfulMigrations =

1x6 struct array with fields:

    className
    renamedFiles

unsuccessfulMigrations =

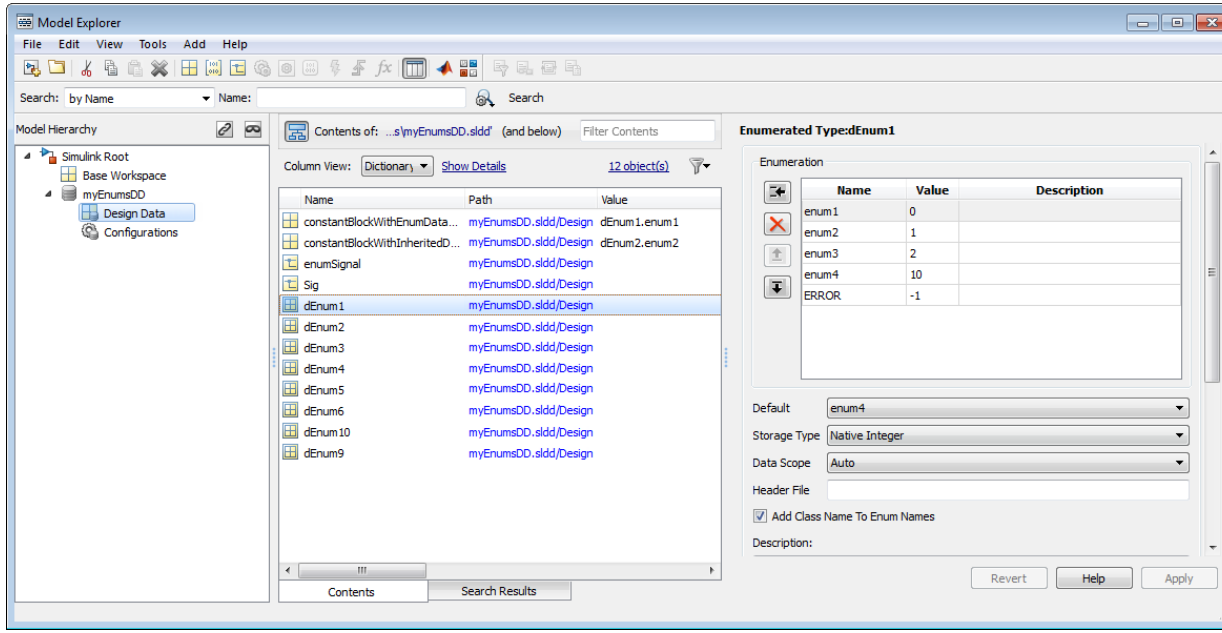
1x2 struct array with fields:

    className
    reasons
```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not be migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

4 Open the dictionary to view the migrated enumerated types.



Manipulate Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

- "Rename Enumerated Type Definition" on page 61-17
- "Rename Enumeration Members" on page 61-18
- "Delete Enumeration Members" on page 61-18
- "Change Underlying Value of Enumeration Member" on page 61-18

Rename Enumerated Type Definition

1. In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
2. Find enumeration objects used by your model that are derived from the type with the old name.
3. Replace these objects with those derived from the renamed type.
4. Delete the type with the old name.

Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members as strings, change these strings to match the renamed member.

Delete Enumeration Members

1. Find references in your model to an enumeration member you want to delete.
2. Replace these references with an alternate member.
3. Delete the original member from the enumeration.

Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using `Value` field of `Simulink.Parameter` objects.

1. Find references in your model to an enumeration member whose value you want to change.
2. Make a note of these references.
3. Change the value of the enumeration member.
4. Manually update references to the enumeration member in your model.

Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

In this section...
“Import Data to Dictionary from File” on page 61-19
“Export Design Data from Dictionary” on page 61-24

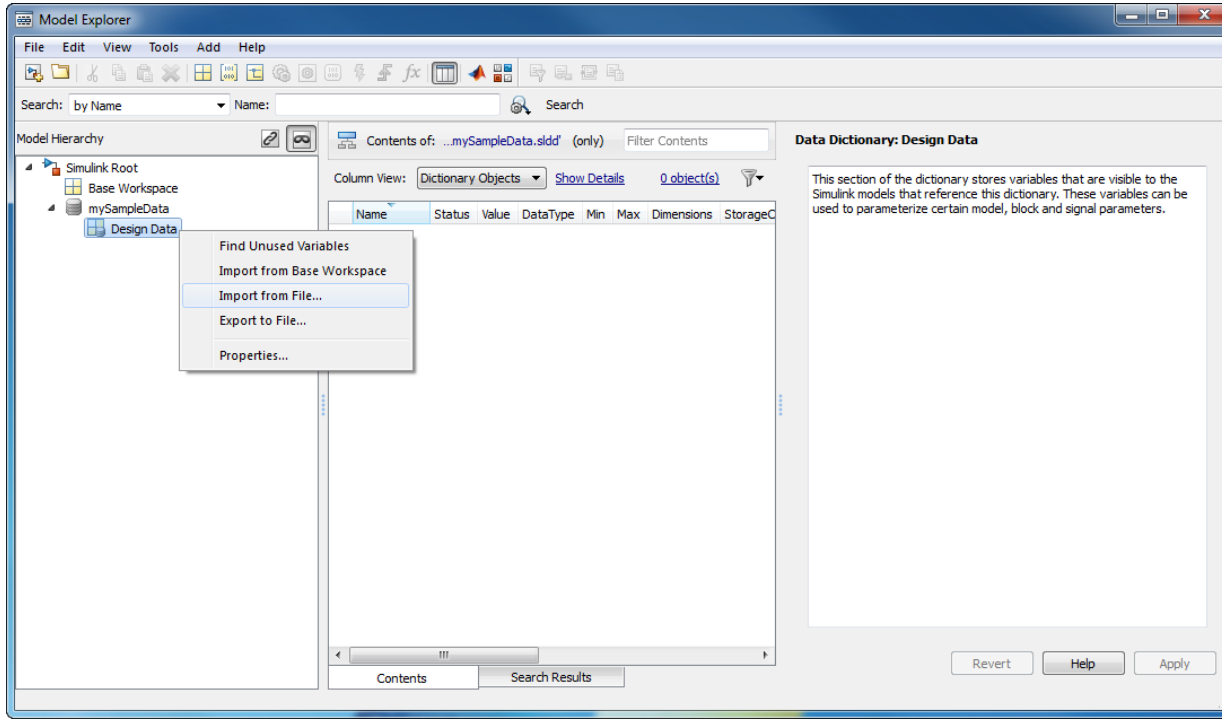
Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

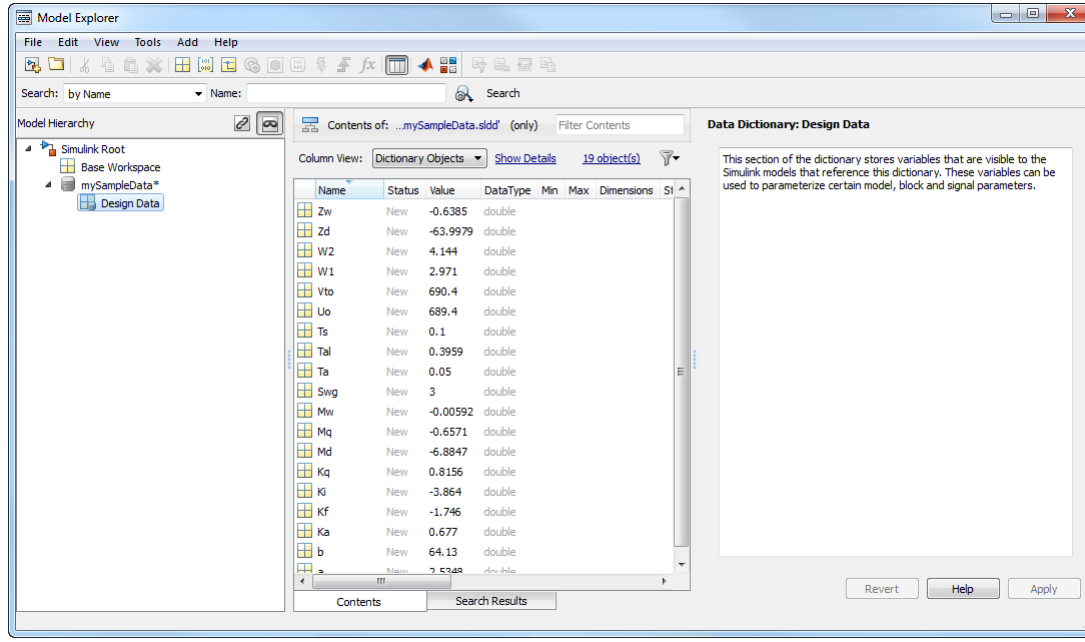
Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

1. In the Simulink Editor, select **View** > **Model Explorer** to open the Model Explorer.
2. Click **File** > **Open**. Then browse to an existing dictionary.
3. In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.



Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

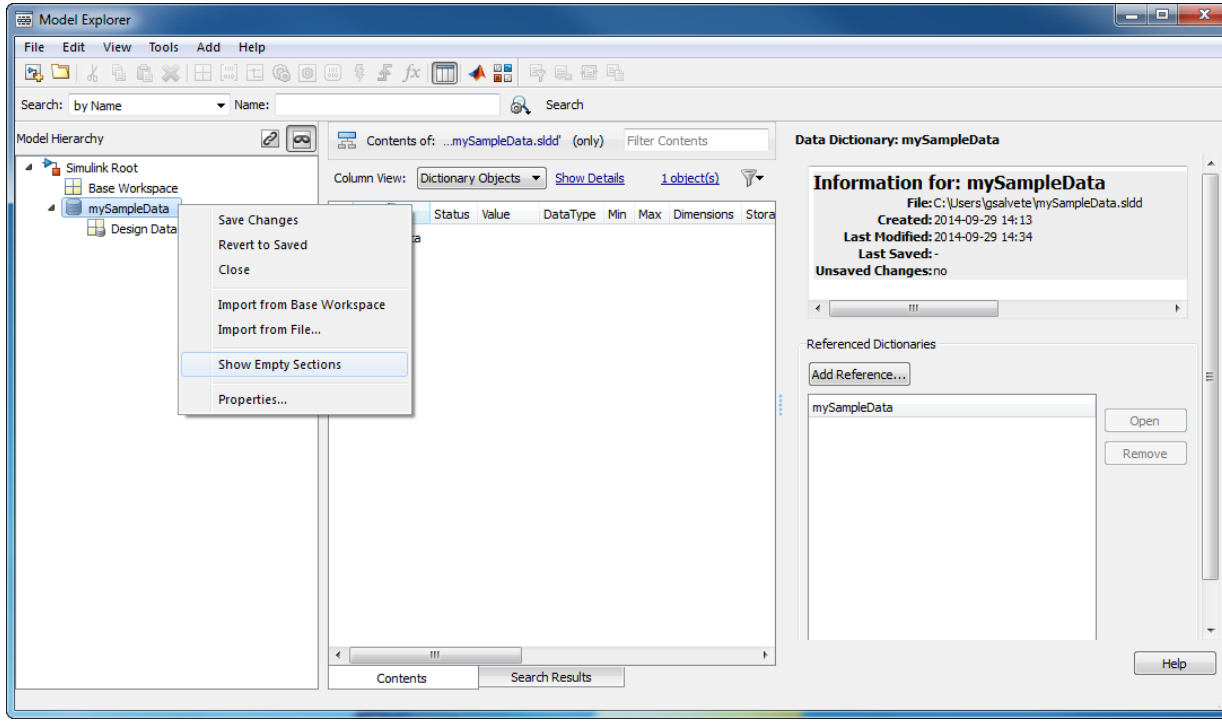


If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

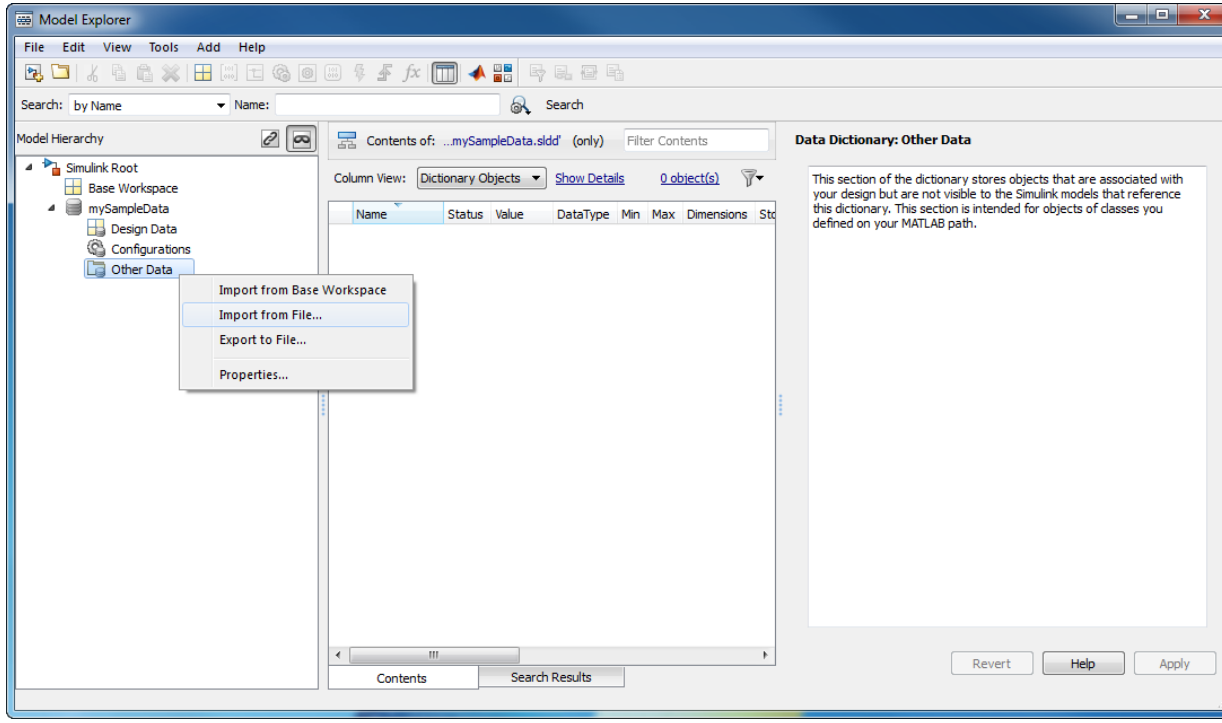
Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

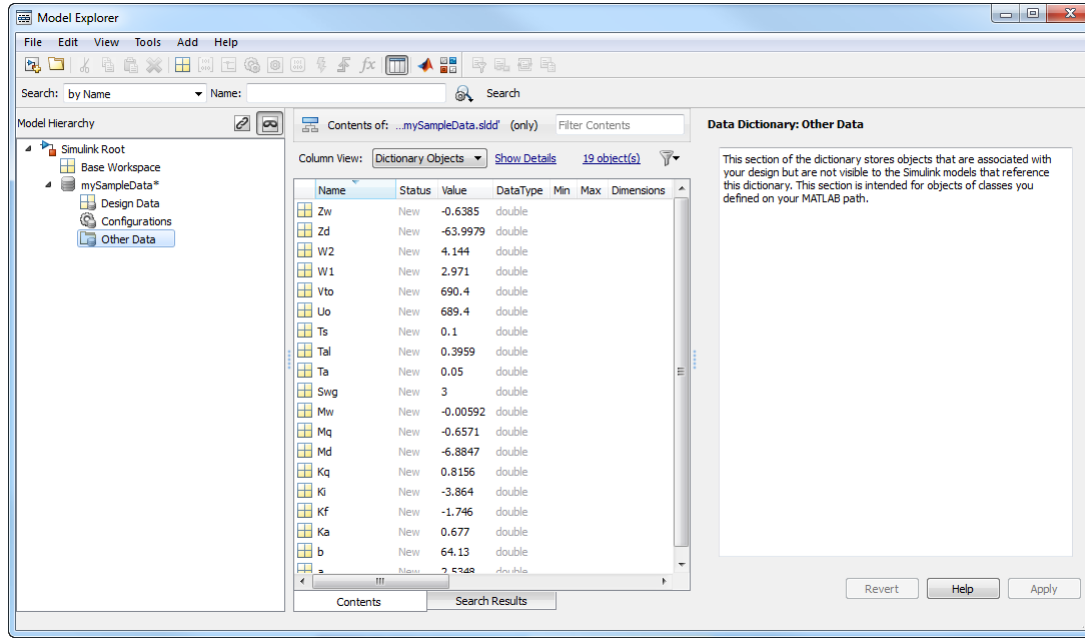
1. In the Simulink Editor, select **View** > **Model Explorer** to open the Model Explorer.
2. Click **File** > **Open**. Then browse to an existing dictionary.
3. In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.



4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.



Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

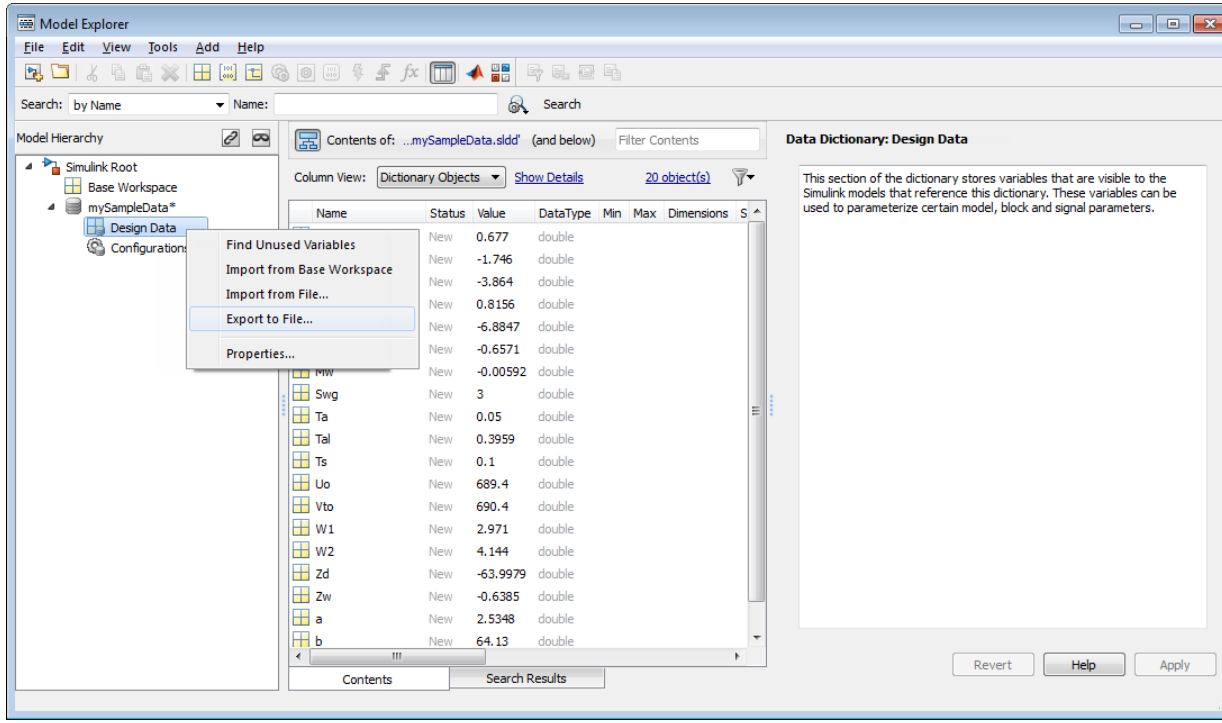


If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

1. In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
2. Open a data dictionary using **File > Open Data Dictionary**.
3. In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data > Export to File**. Then save the design data to a MAT-file or MATLAB script.



Related Examples

- "View and Revert Changes to Dictionary Data" on page 61-26
- "Migrate Models to Use Simulink Data Dictionary" on page 61-5

View and Revert Changes to Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

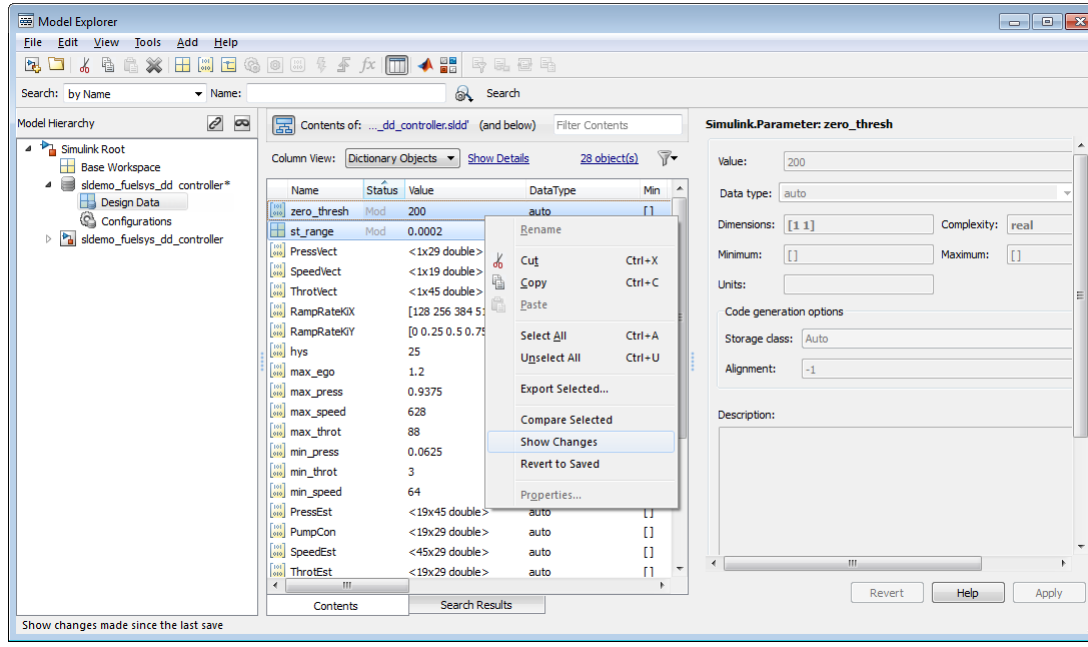
In this section...
“View and Revert Changes to Dictionary Entries” on page 61-26
“View and Revert Changes to Entire Dictionary” on page 61-30

View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

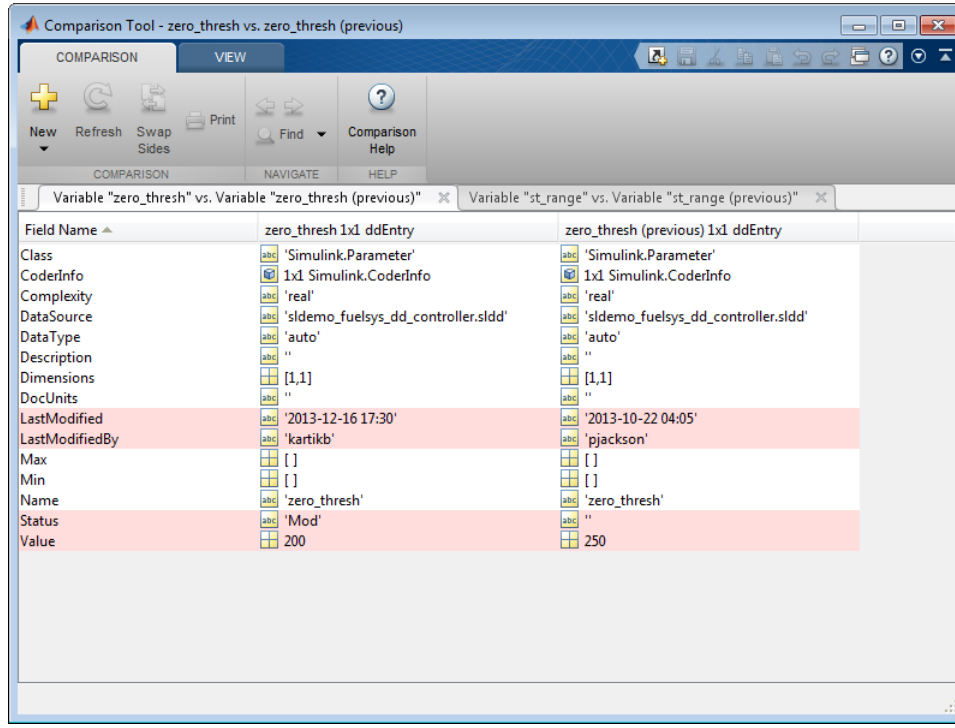
1. Open the `sldemo_fuelsys_dd_controller` model.
2. Open the data dictionary linked to this model by clicking the data dictionary badge in the bottom left corner of each model.
3. In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

   The **Status** column of these entries changes to `Mod`, indicating that they have been modified.
4. Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the `Mod` status.

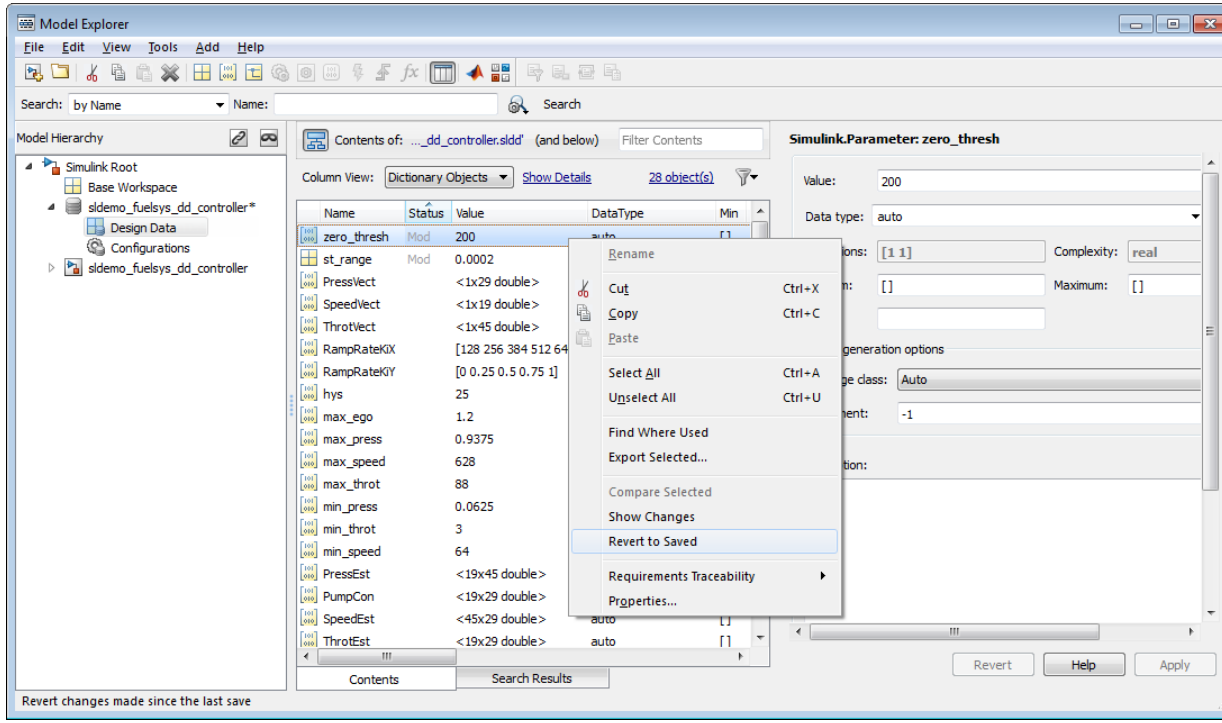


5 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.



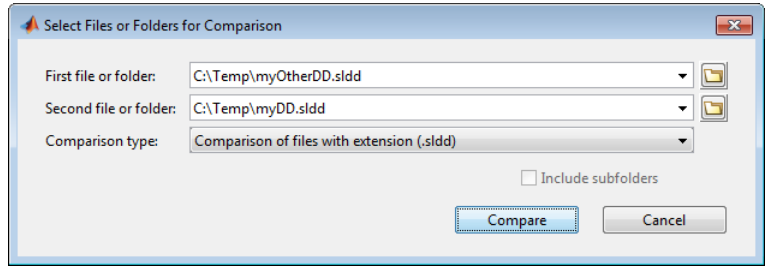
6 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.



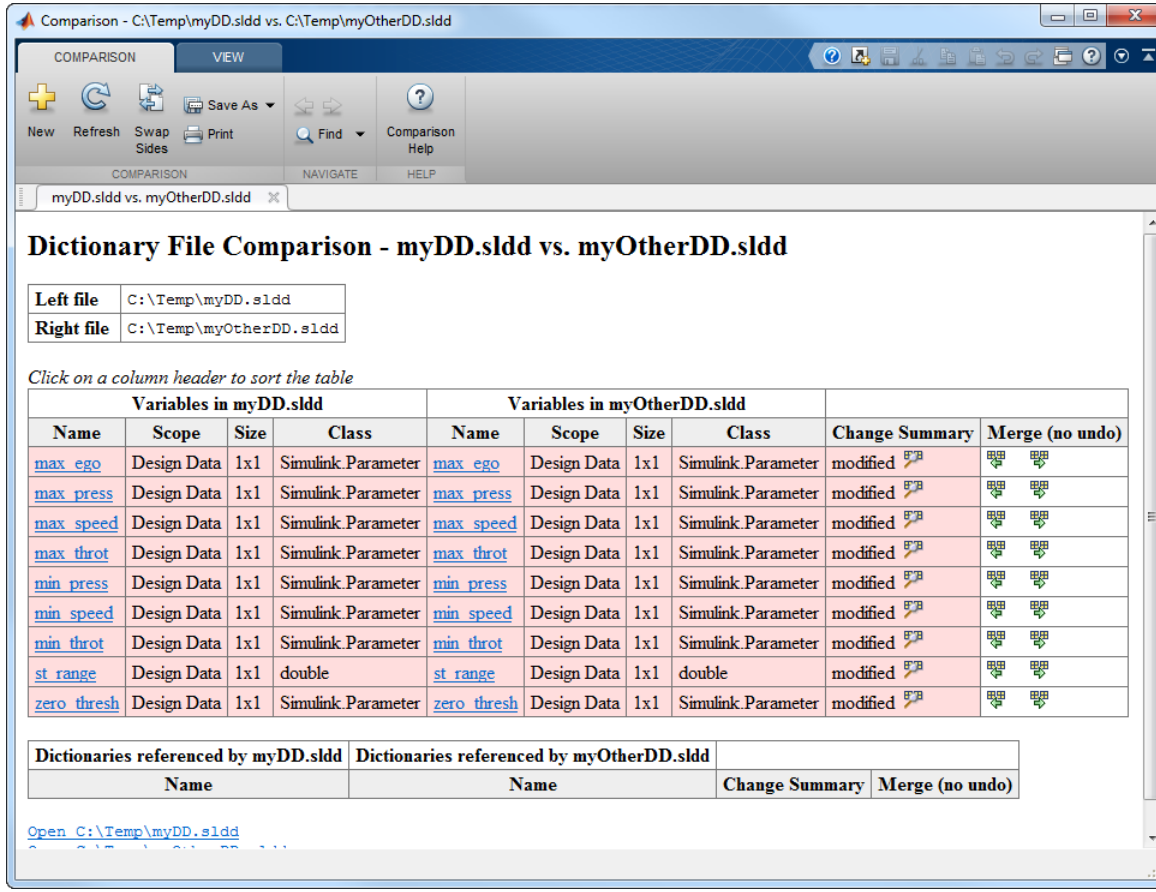
Simulink reverts `zero_thresh` to its value at the time of the last save action.

7 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.

8 Select the dictionaries to compare and merge.



9 In the comparison report, select the merge direction for each dictionary entry.



View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

1. View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

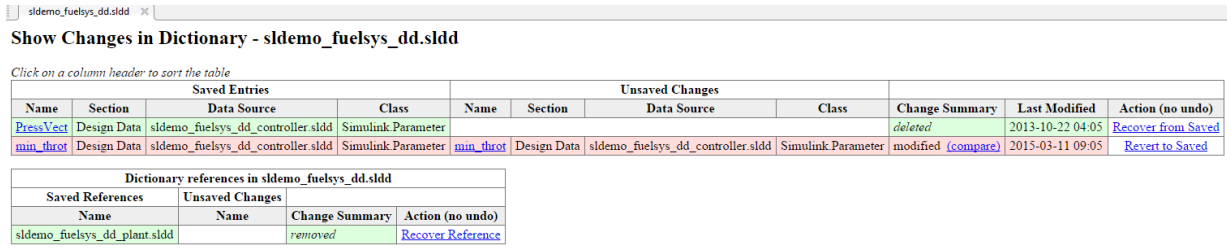
   ```
   dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
   show(dictionary)
   ```

   The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

2. Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.

3. In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

   The Comparison Tool displays the changes made to the dictionary.



sldemo_fuelsys_dd.sldd

Show Changes in Dictionary - sldemo_fuelsys_dd.sldd

Click on a column header to sort the table

Saved Entries				Unsaved Changes						
Name	Section	Data Source	Class	Name	Section	Data Source	Class	Change Summary	Last Modified	Action (no undo)
PressVect	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter					*deleted*	2013-10-22 04:05	Recover from Saved
min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter	min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter	modified (compare)	2015-03-11 09:05	Revert to Saved

Dictionary references in sldemo_fuelsys_dd.sldd			
Saved References	Unsaved Changes		
Name	Name	Change Summary	Action (no undo)
sldemo_fuelsys_dd_plant.sldd		*removed*	Recover Reference

4. In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

   A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from `3` to `4`.

5. Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

   The entry reverts to the definition from the last saved version of the dictionary.

6. The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.

7 The table **Dictionary references in sldemo_fuelsys_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

Related Examples

- "What Is a Data Dictionary?" on page 61-2

Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

Open dictionary for partitioning

1. Open the Model Explorer. In the Simulink Editor, select **View > Model Explorer**.
2. Click **File > Open**.

   Browse and locate your dictionary.

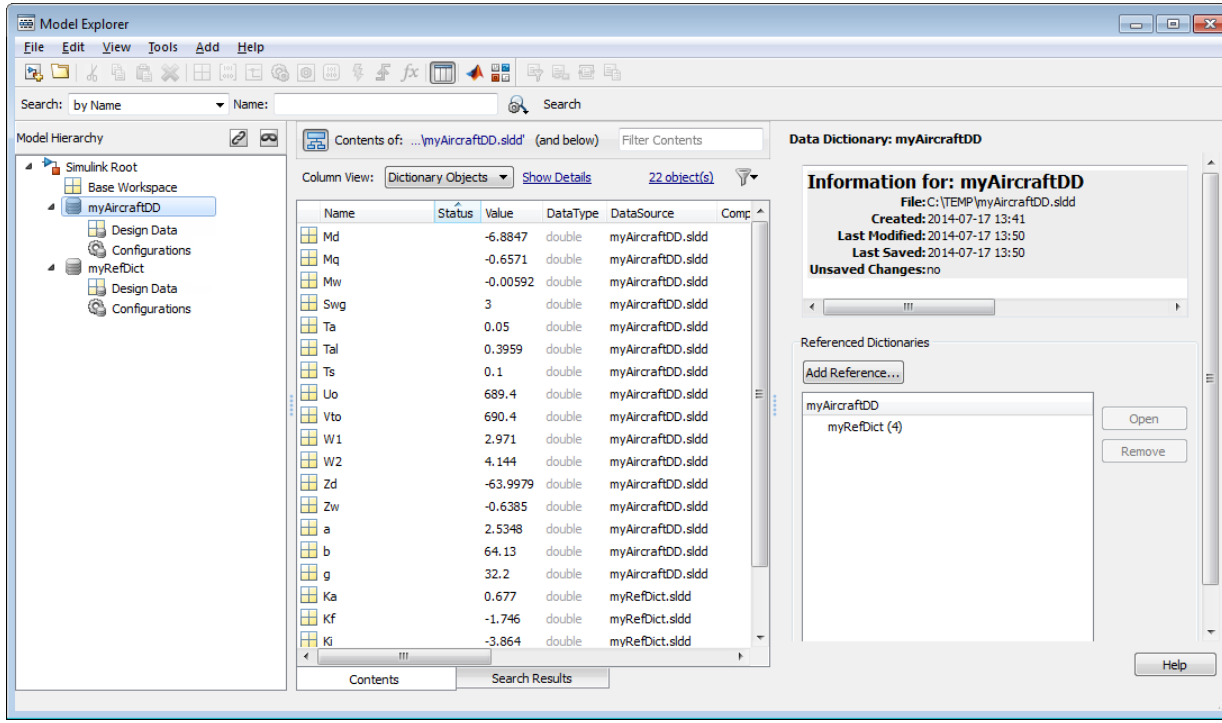
Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

1. Click **File > New > Data Dictionary**.

   Name the reference dictionary and save it.

   Both dictionaries appear as nodes in the **Model Hierarchy** pane.
2. In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
3. In the dialog box pane, in the **Referenced Dictionaries** section, click **Add Reference**. Browse to the location of the reference dictionary and add it as a reference.



Move entries into reference dictionary

1. In the **Model Hierarchy** pane, select the **Design Data** node of the parent dictionary.
2. In the **Contents** pane, select the entries you want to move to the reference dictionary.
3. For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

   To make the **DataSource** column visible, click **Show Details** in the **Contents** pane. In the text box, enter `DataSource`, and add `DataSource` to the list of displayed columns.

Organize display of entries

1. Click the name of the **DataSource** column to sort the entries by the dictionaries that define them.

2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

- "What Is a Data Dictionary?" on page 61-2

Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see "What Is a Data Dictionary?" on page 61-2.

You can migrate all of the models in a model reference hierarchy to use one or more data dictionaries using either of these techniques:

- Migrate all of the models in the hierarchy at once to use a single dictionary. Then, create separate referenced dictionaries to organize the design data.
- Incrementally migrate by beginning with the models at the bottom of the hierarchy. Use this technique if you cannot migrate all of the models at once.

Create a Dictionary for Each Component

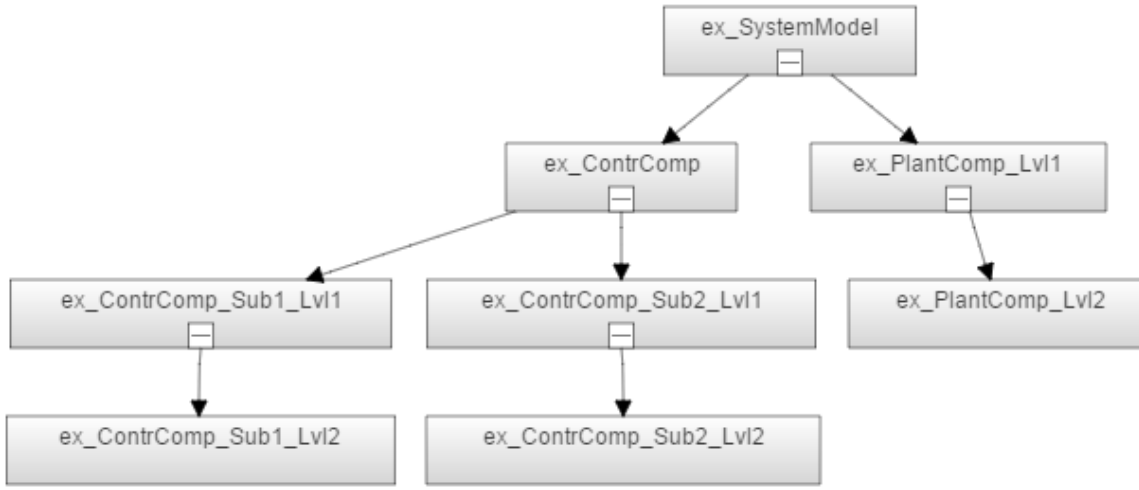
This example shows how to partition design data into dictionaries. When you finish, each component and subcomponent in the system has a dictionary, and dictionary references allow the components and subcomponents to share data.

Explore Example Model Hierarchy

1. Navigate to the folder *`matlabroot`*`/help/toolbox/simulink/examples` (open).
2. Copy these files to a writable folder:
   - `ProjectData.mat`
   - `ex_SystemModel`
   - `ex_PlantComp_Lvl1`
   - `ex_PlantComp_Lvl2`
   - `ex_ContrComp`
   - `ex_ContrComp_Sub1_Lvl1`
   - `ex_ContrComp_Sub1_Lvl2`
   - `ex_ContrComp_Sub2_Lvl1`

- `ex_ContrComp_Sub2_Lvl2`

3. Load the MAT-file `ProjectData.mat` to create design data in the base workspace.
4. Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.
5. Select **Analysis** > **Model Dependencies** > **Model Dependency Viewer** > **Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component. The controller component contains two subcomponents, each of which consist of two models.



6. In the model, update the diagram. The signals in the model use the `Simulink.Bus` objects `SensorBus` and `CtrlBus` in the base workspace.

   The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` also use the bus objects. Therefore, the plant and controller components share the objects.
7. In the MATLAB base workspace, double-click the bus object `SensorBus` to view it in the Bus Editor. The data type of each signal element is set to `FloatType`, which is a `Simulink.NumericType` object in the base workspace.

   All of the models in the hierarchy use `FloatType` to control the data types of signals and parameters.
8. In the Model Explorer **Model Hierarchy** pane, expand the node ex_SystemModel.

The node Reference to SimConfigSet appears. `SimConfigSet` is a `Simulink.ConfigSet` object in the base workspace. All of the models in the hierarchy use references to `SimConfigSet` to maintain configuration parameter uniformity for simulation.

9 Right-click the node Controller (ex_ContrComp) and select **Open**. In the Model Explorer **Model Hierarchy** pane, expand the new node ex_ContrComp.

The nodes Reference to SimConfigSet and Reference to CodeGenConfigSet appear. `CodeGenConfigSet` is a `Simulink.ConfigSet` object in the base workspace. All of the models in the controller component use references to `CodeGenConfigSet` to maintain configuration parameter uniformity for code generation. The models in the plant component do not use `CodeGenConfigSet`.

10 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by `Constant` blocks in the models `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables `coeff`, `init`, and `mu`.

The table shows the models that share each variable in the base workspace.

Variable Name	Models Using the Variable	Scope of Sharing
`SimConfigSet`	All models in the hierarchy	Shared globally by entire system
`FloatType`	All models in the hierarchy	Shared globally by entire system
`CtrlBus`	All models in the hierarchy	Shared globally by entire system
`SensorBus`	All models in the hierarchy	Shared globally by entire system
`CodeGenConfigSet`	All models in the controller component	Shared by controller subcomponents

Variable Name	Models Using the Variable	Scope of Sharing
`init`	`ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub2_Lvl1`	Shared by controller subcomponents
`diff`	`ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`	Shared by models in the first controller subcomponent
`coeff`	`ex_ContrComp_Sub2_Lvl1` and `ex_ContrComp_Sub2_Lvl2`	Shared by models in the second controller subcomponent
`mu`	`ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`	Shared by models in plant component

Suppose that three teams of developers maintain the plant component and the two controller subcomponents. You can use data dictionaries to store and scope the shared design data.

Create System Dictionary

1. In the model `ex_SystemModel`, select **File** > **Model Properties** > **Link to Data Dictionary**.
2. In the dialog box, under **Defined in**, select **Data Dictionary**. Click **New**.
3. Set the new dictionary name to `System` and click **Save**.
4. In the **Model Properties** dialog box, click **OK**.
5. Click **Yes** in response to the message about migrating workspace data.
6. Click **Yes** in response to the message about removing imported items from the base workspace.
7. Save the model.

You can simulate and generate code from the models in the hierarchy. All of the models in the hierarchy are linked to the dictionary. All of the variables in the base workspace now reside in the new dictionary `System.sldd`.

Create Dictionary for Plant Component

1. Open the model `ex_PlantComp_Lvl1`.
2. Select **File** > **Model Properties** > **Link to Data Dictionary**.

3. In the dialog box, under **Defined in**, click **New**.
4. Set the new dictionary name to `Plant` and click **Save**.
5. In the **Model Properties** dialog box, click **OK**.
6. In response to the message, click **Move Data**.
7. Click **Yes** in response to the message about migrating data.
8. Save the model.

The models in the plant component, `ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`, are linked to the new dictionary `Plant.sldd`. The other models in the hierarchy remain linked to `System.sldd`. Because the model `ex_PlantComp_Lvl1` uses globally shared variables such as `CtrlBus` and `FloatType`, the migration process moves the variables to `Plant.sldd`. However, `System.sldd` references `Plant.sldd`, so all of the models in the hierarchy can continue to use the globally shared variables.

The variable that the plant models share, `mu`, also resides in `Plant.sldd`. Other variables such as `init` and `diff` remain in `System.sldd`.

The plant component can stand alone from the rest of the system because all of its data is in `Plant.sldd`. However, the controller component depends on the shared data that is also defined in `Plant.sldd`.

Create Dictionary for Controller Component

Open the model `ex_ContrComp`, which is the top model in the controller component. Link this model to a new dictionary named `Contr.sldd`. Then, save the model.

When you finish, the five models in the controller component are linked to `Contr.sldd`. Because the globally shared variables such as `CtrlBus` and `FloatType` still reside in the dictionary `Plant.sldd`, the dictionary `Contr.sldd` references `Plant.sldd`. Due to this reference, the models in the controller component can continue to use the globally shared variables.

The variables that the controller models share, such as `diff`, `init`, and `CodeGenConfigSet`, now reside in `Contr.sldd`.

Create Dictionary for First Controller Subcomponent

Open the model `ex_ContrComp_Sub1_Lvl1`. Link this model to a new dictionary named `ContrSub1.sldd`. Then, save the model.

When you finish, the models in the first controller subcomponent, `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, are linked to `ContrSub1.sldd`. The models in the second subcomponent remain linked to the dictionary `Contr.sldd`.

Create Dictionary for Second Controller Subcomponent

Open the model `ex_ContrComp_Sub2_Lvl1`. Link this model to a new dictionary named `ContrSub2.sldd`. Then, save the model.

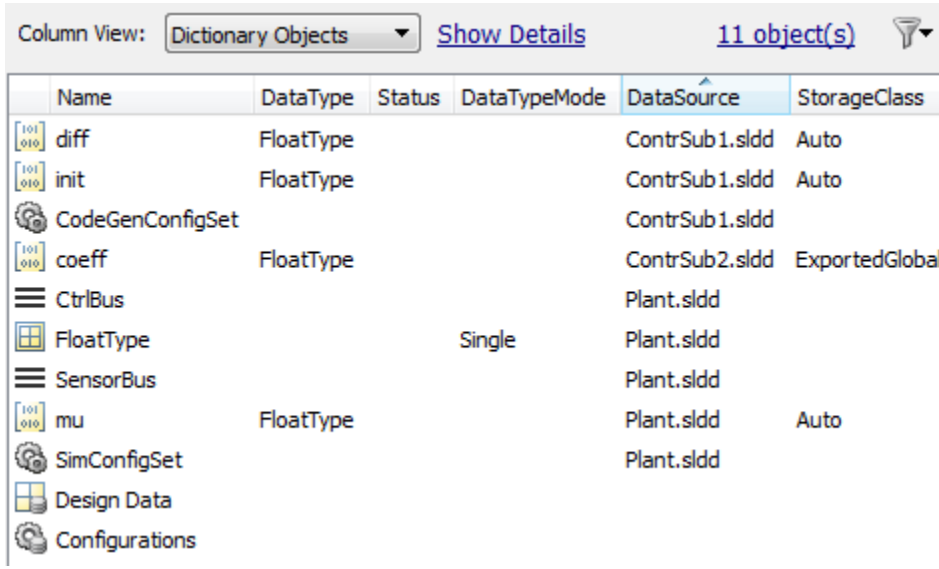
The controller dictionary `Contr.sldd` references the subcomponent dictionaries, `ContrSub1.sldd` and `ContrSub2.sldd`. Therefore, the controller dictionary can use all of the data defined in the subcomponent dictionaries.

The first subcomponent dictionary, `ContrSub1.sldd`, defines data that the subcomponents share, such as `CodeGenConfigSet`. The second subcomponent dictionary, `ContrSub2.sldd`, references `ContrSub1.sldd` so that the second subcomponent can use this shared data.

The subcomponent dictionaries `ContrSub1.sldd` and `ContrSub2.sldd` reference `Plant.sldd`. Therefore, all of the models in the hierarchy can continue to use globally shared variables such as `SensorBus` and `SimConfigSet`, which are defined in `Plant.sldd`.

Inspect Data Storage

In the Model Explorer **Model Hierarchy** pane, select the dictionary node System. In the **Contents** pane, to view the contents of `System.sldd`, click the **Show Current System and Below** button . The contents of the Design Data and Configurations sections appear.



The **DataSource** column shows the variables that each dictionary stores.

All of the globally shared variables, such as `FloatType` and `SimConfigSet`, reside in `Plant.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `ContrSub1.sldd`. Due to dictionary references created by the migration process, the models can still share these variables.

If the development teams assigned to the controller subcomponents must make changes to the globally shared variables, they must access the plant dictionary file. Similarly, if the team assigned to the second controller subcomponent must make changes to the variable `init`, they must access the first subcomponent dictionary file.

Optimize Data Sharing Using Reference Dictionaries

To share global variables such as `SimConfigSet`, `FloatType`, and `SensorBus` by clearly defining variable scope, you can create a reference dictionary. Add the new dictionary as a reference to all of the component and subcomponent dictionaries that require the shared data.

1 Close all of the models that you have open.

```
bdclose all
```

2. In Model Explorer, select **File** > **New** > **Data Dictionary**.
3. Set the new dictionary name to `GlobalShare` and click **Save**.
4. In the **Model Hierarchy** pane, select the node ContrSub2. In the Dialog pane, click **Add Reference**.
5. Double-click `GlobalShare.sldd`.
6. In the **Model Hierarchy** pane, right-click the node ContrSub2 and select **Save Changes**.
7. Add `GlobalShare.sldd` as a reference to the dictionaries `ContrSub1.sldd` and `Plant.sldd`. Save each dictionary after you add the reference.
8. In the **Model Hierarchy** pane, select the node System.
9. In the **Contents** pane, select the globally shared variables:
   - `CtrlBus`
   - `SensorBus`
   - `SimConfigSet`
   - `FloatType`
10. In the **DataSource** column, select `GlobalShare.sldd` for any of the selected variables.

    All of the variables move from `Plant.sldd` to `GlobalShare.sldd`.
11. Save changes to the dictionary `System.sldd`.

Now, if any of the three development teams need to make changes to the globally shared variables such as `SimConfigSet` and `CtrlBus`, they can access the dictionary `GlobalShare.sldd`. This dictionary contains only the variables that all of the models in the system share. Because the component and subcomponent dictionaries `Plant.sldd`, `ContrSub1.sldd`, and `ContrSub2.sldd` all reference the globally shared dictionary `GlobalShare.sldd`, all of the models in the hierarchy can use the data.

To further partition and scope the shared data, create another reference dictionary to contain the variables that the controller subcomponents share: `init` and `CodeGenConfigSet`.

1. In Model Explorer, select **File** > **New** > **Data Dictionary**.
2. Set the new dictionary name to `ContrShare` and click **Save**.
3. In the **Model Hierarchy** pane, select the dictionary node ContrSub2. In the Dialog pane, select **Add Reference**.

4. In the dialog box, double-click `ContrShare.sldd`.
5. In the **Model Hierarchy** pane, right-click the node ContrSub2 and select **Save Changes**.
6. Add `ContrShare.sldd` as a reference to `ContrSub1.sldd` and save the dictionary `ContrSub1.sldd`.
7. Add `GlobalShare.sldd` as a reference to `ContrShare.sldd` and save the dictionary `ContrShare.sldd`.
8. In the **Model Hierarchy** pane, select the node System.
9. In the **Contents** pane, select these variables:
   - `CodeGenConfigSet`
   - `init`
10. In the **DataSource** column, select `ContrShare.sldd` for any of the selected variables.

    All of the variables move from `ContrSub2.sldd` to `ContrShare.sldd`.
11. Save changes to the dictionary `System.sldd`.

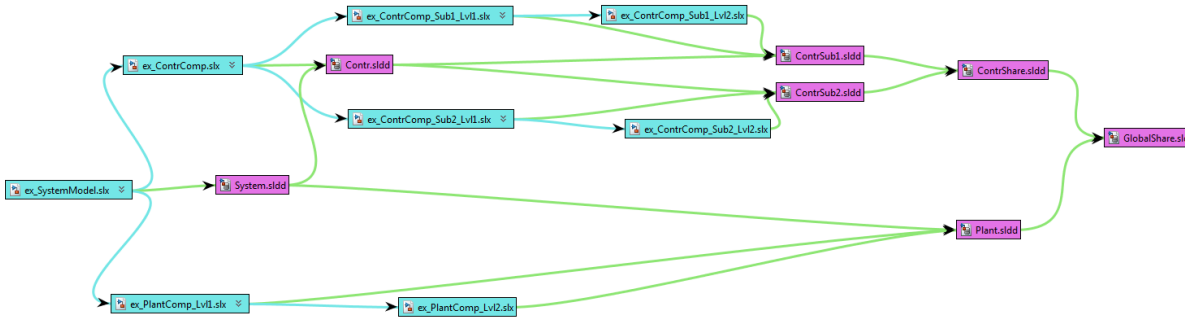
To further optimize the dictionary hierarchy, remove the unnecessary references that the migration process created. Also, remove the unnecessary references that you created from `ContrSub1.sldd` and `ContrSub2.sldd` to `GlobalShare.sldd`. Because `ContrShare.sldd` references `GlobalShare.sldd`, the controller subcomponent dictionaries can use the data in `GlobalShare.sldd` without referencing `GlobalShare.sldd`.

1. In the Model Explorer **Model Hierarchy** pane, select the dictionary node ContrSub2. In the Dialog pane, in the **Referenced Dictionaries** list, select Plant and click **Remove**. Remove the references to `GlobalShare.sldd` and `ContrSub1.sldd`. Save the changes to `ContrSub2.sldd`.
2. Remove the references to `GlobalShare.sldd` and `Plant.sldd` from `ContrSub1.sldd`. Save the changes to `ContrSub1.sldd`.
3. Remove the reference to `Plant.sldd` from `Contr.sldd`. Save the changes to `Contr.sldd`.

Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

1. Open your saved model `ex_SystemModel`. Select **File** > **Simulink Project** > **Create Project from Model**.
2. Specify a name for the project in the **Project name** box. Click **Create**.
3. In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.



The system model, `ex_SystemModel`, is linked to the dictionary `System.sldd`. The plant component, the controller component, and the controller subcomponents are each linked to a separate dictionary. These dictionaries form a reference hierarchy. To access the shared data, the component and subcomponent dictionaries reference the dictionaries `ContrShare.sldd` and `GlobalShare.sldd`.

To inspect the data in the dictionaries, use Model Explorer.

1. In your saved model `ex_SystemModel`, click the data dictionary badge .
2. In the Model Explorer **Contents** pane, click the column name **DataSource** to sort the design data. The dictionaries in the hierarchy partition the data based on the shared scope of each variable.

   You can also right-click the column name and select **Group by This Column** to group the entries by the dictionaries that define them.
3. In the **Model Hierarchy** pane, under the node System, click the node Configurations. In the **Contents** pane, the `Simulink.ConfigSet` objects `CodeGenConfigSet` and `SimConfigSet` are stored in the shared dictionaries.

Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, select **Edit > Find Referenced Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see "Workspace Variables in Model Explorer" on page 12-51.
- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function intersect to determine the variables two models, components, or subcomponents share.

Migrate Model Hierarchy to Dictionaries Incrementally

If you cannot migrate all of the models in a model reference hierarchy to a single dictionary at once, you can migrate an individual model, component, or subcomponent at the bottom of the hierarchy. Over time, you can migrate the entire hierarchy.

If you want to simulate and generate code from the hierarchy after you migrate each component, the components that you migrate cannot share any design data with other models in the hierarchy. In the example "Create a Dictionary for Each Component" on page 61-36, the components and subcomponents of a model reference hierarchy share data in the base workspace, such as `Simulink.Bus` and `Simulink.Parameter` objects. Due to these dependencies, if you migrate the hierarchy incrementally from the bottom, you cannot simulate or generate code from the hierarchy until you migrate all of the models.

Similarly, if you use configuration set references to maintain configuration parameter uniformity throughout the hierarchy, the component that you choose to migrate cannot share a configuration set with other models in the hierarchy. To permit simulation and code generation after you migrate the component, you must eliminate the dependency that the component has on the shared configuration set.

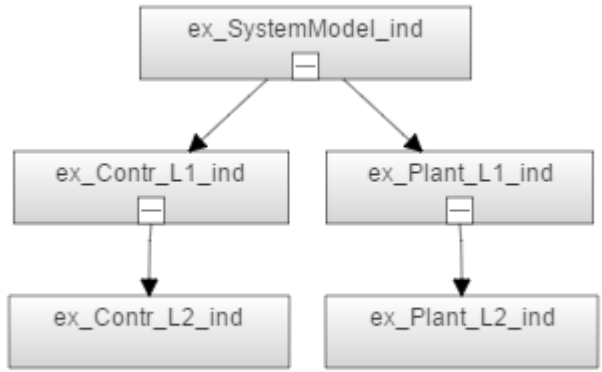
For example, when you migrate the component, copy the shared configuration set from the base workspace into the new dictionary. Then, rename the configuration set in the data dictionary, and set all of the models in the migrated component to use this renamed configuration set. The models in the migrated component use the configuration set in the data dictionary, while the rest of the models in the hierarchy use the configuration set in the base workspace. As you migrate additional components, set the models in each component to use the configuration set in the data dictionary.

If you choose to migrate a model reference hierarchy incrementally by using this technique, you must begin with the models or components at the bottom of the hierarchy. In the example "Create a Dictionary for Each Component" on page 61-36, a

controller model references two subcomponents, each of which contains two models. You cannot migrate the controller model before you migrate the models in the controller subcomponents.

Explore Example Model Hierarchy

1. Navigate to the folder *`matlabroot`*`/help/toolbox/simulink/examples` (open).
2. Copy these files to a writable folder:
   - `ProjectData_ind.mat`
   - `ex_SystemModel_ind`
   - `ex_Plant_L1_ind`
   - `ex_Plant_L2_ind`
   - `ex_Contr_L1_ind`
   - `ex_Contr_L2_ind`
3. Load the MAT-file `ProjectData_ind.mat` to create design data in the base workspace.
4. Open the example model `ex_SystemModel_ind`. This model is at the top of a reference hierarchy that includes the other example models.
5. Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component with two models.



6 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel_ind` and click **OK**. If you see a message about updating the diagram, click **OK**.

   In the **Contents** pane, the variable `diff` is used by `Constant` blocks in the models `ex_Contr_L1_ind` and `ex_Contr_L2_ind`, which make up the controller component. Similarly, other models in the hierarchy share the base workspace variable `mu`.

The table shows the models that share each workspace variable.

Variable Name	Models Using the Variable	Scope of Sharing
`diff`	`ex_ContrComp_Lvl1` and `ex_ContrComp_Lvl2`	Shared by models in the controller component
`mu`	`ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`	Shared by models in plant component

Suppose that two teams of developers maintain the plant component and the controller component. You can use data dictionaries to store and scope the design data. The teams can incrementally migrate the components to use data dictionaries.

Create Data Dictionary for Controller Component

Suppose that only the controller component team is ready to migrate their models to a data dictionary. You can independently migrate these two models.

1 Open the example model `ex_Contr_L1_ind`. This model is at the top of the controller component.

2 Select **File** > **Model Properties** > **Link to Data Dictionary**.

3 In the dialog box, under **Defined in**, select **Data Dictionary** and click **New**.

4 Set the new dictionary name to `Contr` and click **Save**.

5 In the **Model Properties** dialog box, click **OK**.

6 Click **Yes** in response to the message about migrating workspace data.

7 Click **Yes** in response to the message about removing imported items from the base workspace.

8 Save the model.

You can simulate and generate code from the model hierarchy. The models in the controller component use the data in the dictionary `Contr`, which contains the variable `diff`. The other models in the hierarchy continue to use the data in the base workspace.

Create Data Dictionary for Plant Component

Open the example model `ex_Plant_L1_ind`. Link this model to a new data dictionary `Plant.sldd`. After you link the model to the new dictionary, save the model.

The migration process moves the variable `mu` into the new dictionary.

Create Data Dictionary for System Model

Open the example model `ex_SystemModel_ind`. Link this model to a new data dictionary `System.sldd`. After you link the model to the new dictionary, save the model.

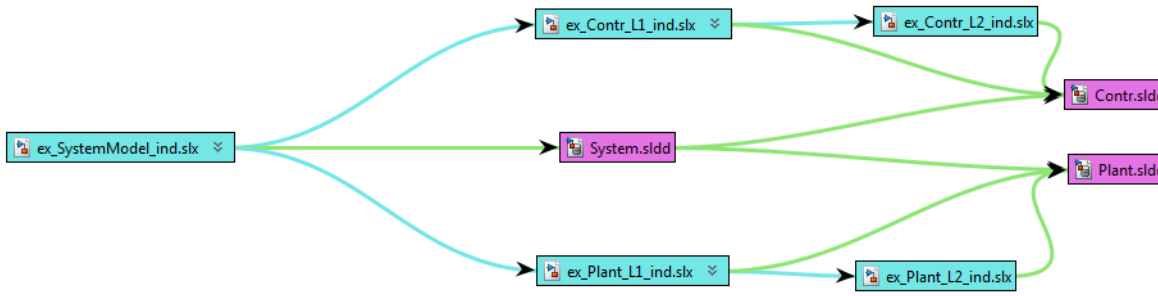
The migration process causes the new dictionary, `System.sldd`, to reference the other dictionaries that you created.

Inspect Dictionary Hierarchy

Each of the components has a data dictionary. To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

1. In your saved model `ex_SystemModel_ind`, select **File** > **Simulink Project** > **Create Project from Model**.
2. Specify a name for the project in the **Project name** box. Click **Create**.
3. In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

Each team's models are linked to the appropriate dictionaries. The system dictionary references the component dictionaries.



To inspect the data in the dictionaries, use the Model Explorer.

1. In your saved model `ex_SystemModel_ind`, click the data dictionary badge .
2. In the Model Explorer **Contents** pane, the data source for each entry is the dictionary for the appropriate component.

Data Dictionary Management

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace. Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

Goal	Use
Represent existing data dictionary with `Simulink.data.Dictionary` object	`Simulink.data.dictionary.open`
Create and represent data dictionary with `Simulink.data.Dictionary` object	`Simulink.data.dictionary.create`
Interact with data dictionary	Simulink.data.Dictionary class
Import variables to data dictionary from MATLAB base workspace	`Simulink.data.Dictionary.importFromBaseWorkspace` method
Add reference dictionary to a data dictionary	`Simulink.data.Dictionary.addDataSource` method

Goal	Use
Remove reference dictionary from a data dictionary	`Simulink.data.Dictionary.removeDataSource` method
Save changes to data dictionary	`Simulink.data.Dictionary.saveChanges` method
Discard changes to data dictionary	`Simulink.data.Dictionary.discardChanges` method
View a list of entries stored in data dictionary	`Simulink.data.Dictionary.listEntry` method
Import enumerated type definitions to data dictionary	`Simulink.data.Dictionary.importEnumTypes` method
Return file name and path of data dictionary	`Simulink.data.Dictionary.filepath` method
Show data dictionary in Model Explorer window	`Simulink.data.Dictionary.show` method
Hide data dictionary from Model Explorer window	`Simulink.data.Dictionary.hide` method
Close connection between data dictionary and `Simulink.data.Dictionary` object	`Simulink.data.Dictionary.close` method
Identify data dictionaries that are open	`Simulink.data.dictionary.getOpenDictionaryPaths`
Close all connections to all open data dictionaries	`Simulink.data.dictionary.closeAll`

Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

Goal	Use
Represent data dictionary section with `Section` object.	`Simulink.data.Dictionary.getSection` method

Goal	Use
Interact with data dictionary section	Simulink.data.dictionary.Section class
Import variables to data dictionary section from MAT-file or MATLAB file	`Simulink.data.dictionary.Section.importFromFile` method
Export entries in data dictionary section to MAT-file or MATLAB file	`Simulink.data.dictionary.Section.exportToFile` method
Delete entry from data dictionary section	`Simulink.data.dictionary.Section.deleteEntry` method
Evaluate MATLAB expression in data dictionary section	`Simulink.data.dictionary.Section.evalin` method
Search for entries in data dictionary section	`Simulink.data.dictionary.Section.find` method
Determine whether entry exists in data dictionary section	`Simulink.data.dictionary.Section.exist` method

Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

Goal	Use
Represent data dictionary entry with `Entry` object	`Simulink.data.dictionary.Section.getEntry` method
Add data dictionary entry to section and represent with `Entry` object	`Simulink.data.dictionary.Section.addEntry` method
Manipulate data dictionary entry	Simulink.data.dictionary.Entry class
Assign new value to data dictionary entry	`Simulink.data.dictionary.Entry.setValue` method

Goal	Use
Display changes made to data dictionary entry	`Simulink.data.dictionary.Entry.showChanges` method
Save changes made to data dictionary	`Simulink.data.Dictionary.saveChanges` method
Discard changes made to data dictionary entry	`Simulink.data.dictionary.Entry.discardChanges` method
Search in an array of data dictionary entries	`Simulink.data.dictionary.Entry.find` method
Return value of data dictionary entry	`Simulink.data.dictionary.Entry.getValue` method
Delete data dictionary entry	`Simulink.data.dictionary.Entry.deleteEntry` method
Store enumerated type definition in dictionary	Simulink.data.dictionary.EnumTypeDefinition class

Transition to Using Data Dictionary

These functions help you transition to data dictionaries by operating on Simulink model data either in the base workspace or in a data dictionary, as appropriate for the model.

Goal	Use
Change value of data dictionary entry or workspace variable in context of Simulink model	`Simulink.data.assigninGlobal`
Evaluate MATLAB expression in context of Simulink model	`Simulink.data.evalinGlobal`
Determine existence of data dictionary entry or workspace variable in context of Simulink model	`Simulink.data.existsInGlobal`

Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.sldd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

Note: This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page 61-13.

Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

1. Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

	A	B	C	D	E	F	G	H
1		bkpt2Name						
2	bkpt1Name	tableName	0.1	0.2	0.3	0.4	0.5	
3		0.25	0.35	0.6	0.85	1.1	1.35	
4		0.5	0.45	0.7	0.95	1.2	1.45	
5		0.75	0.55	0.8	1.05	1.3	1.55	
6		1	0.65	0.9	1.15	1.4	1.65	
7		1.25	0.75	1	1.25	1.5	1.75	
8								

Save the workbook in your current folder as `my2DLUT.xlsx`.

2 Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
    % IMPORTLUTTODD(workbookFile,dictionaryName) imports data for a
    % two-dimensional lookup table from a workbook directly into a data
    % dictionary. The two-dimensional lookup table in the workbook can be
    % any size but must follow a standard format.

    % Read in the entire first sheet of the workbook.
    [data,names,~] = xlsread(workbookFile,1,'');

    % Divide the raw imported data into the breakpoints, the table, and their
    % names.
    % Assume breakpoint 1 is in the first column and breakpoint 2 is in the
    % first row.
    % Assume cells A1, B1, and B2 define the breakpoint names and table name.
    bkpt1 = data(2:end,1);
    bkpt2 = data(1,2:end);
    table = data(2:end,2:end);
    bkpt1Name = names{2,1};
    bkpt2Name = names{1,2};
    tableName = names{2,2};

    % Prepare to import to the Design Data section of the target data
    % dictionary.
    myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
    dDataSectObj = getSection(myDictionaryObj,'Design Data');

    % Create entries in the dictionary to store the imported breakpoints and
    % table. Name the entries using the breakpoint and table names imported
    % from the workbook.
    addEntry(dDataSectObj,bkpt1Name,bkpt1);
```

```
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)
```

3 At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');
```

4 Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')
```

5 Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a `2-D Lookup Table` block.

Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```
% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD,'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD,'partDD_Data_ex_API.m');
```

```
% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD,typesDDName);
addDataSource(parentDD,paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD,'-value','-class','Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD,'-value','-class','Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
```

Sweep Data Dictionary Parameter Using Parallel Simulation

To use parallel simulation to sweep a model parameter that is defined in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and swept parameter to match your application.

You cannot use this code for parallel Rapid Accelerator Mode or Accelerator Mode simulation. For an example of parallel simulation using Rapid Accelerator Mode, see “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode”.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'myParamSweepMdl';
dd = 'myParamSweepDD.sldd';

% Define parameter sweeping values
ParamValues = [20 35 49 78 106 123 148 192 205 225];
```

```
% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(ParamValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj,'Design Data');
    entryObj = getEntry(sectObj,'SpeedVect');
    % Suppose SpeedVect is a Simulink.Parameter stored in the data dictionary

    % Modify the value of the Simulink.Parameter stored in the data dictionary
    temp = getValue(entryObj);
    temp.Value = ParamValues(index);
    setValue(entryObj,temp);

    % Simulate and store simulation output in the nondistributed array
    simOut{index} = sim(model);

    % Each worker must discard all changes to the data dictionary and
    % close the dictionary when finished with an interation of the parfor-loop
    discardChanges(dictObj);
    close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model
bdclose(model)
spmd
    Simulink.data.dictionary.cleanupWorkerCache
end
```

Note: If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

Signal Basics

In this section...
"About Signals" on page 62-2
"Creating Signals" on page 62-3
"Signal Line Styles" on page 62-3
"Signal Properties" on page 62-4
"Testing Signals" on page 62-6

About Signals

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

Many blocks can accept or output signals of any data or numeric type and dimensionality. Other blocks impose restrictions on the attributes of the signals that they can handle.

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations).

Note Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink

signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

Creating Signals

Create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine block from the Simulink Sources library into your model. For information about blocks that create signals in a model, see “Sources” .

You can use the Signal & Scope Manager to create signals in your model without using blocks. For more information, see “Signal and Scope Manager” on page 25-73 .

Signal Line Styles

A Simulink model can include many different types of signals. For details, see “Signal Types” on page 62-8. Different line styles help you to differentiate the signal types.

As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. The only line style that you can customize is the nonscalar signal type. For information about this option, see “Wide Nonscalar Lines” on page 62-60.

Signal Type	Line Style
Scalar and nonscalar	Nonscalar (with the **Wide nonscalar lines** option enabled—see “Display Signal Attributes” on page 62-57)	
Control signal	Virtual bus	Nonvirtual bus	
Array of buses	
Signal Type	Line Style
Variable-size	

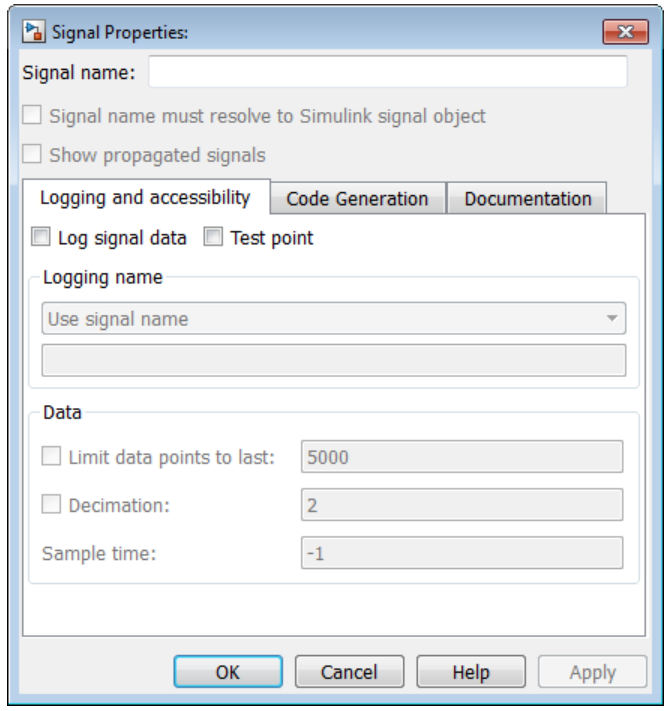
Signal Properties

Specifying Signal Properties

Use the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To open the Signal Properties dialog box, right-click a signal and choose **Properties**.



Signal Names and Labels

You can name a signal. By default, the signal name appears below a signal, displayed as a *signal label*. You can name a signal interactively in the model or by using the Signal Properties dialog box. You can also name the signal at the command prompt (see "Name a Signal Programmatically" on page 1-16). For a summary of how to work with signal names and labels in the Simulink Editor, see "Signal Name and Label Actions" on page 1-87.

The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See "Export Signal Data Using Signal Logging" on page 59-56.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in "Handling Spaces and Newlines in Logged Names" on page 59-94
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends `(signal#)` to all input signal names, where # is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, use the **Display > Signals & Ports** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions
- Signal resolution

For details, see “Display Signal Attributes” on page 62-57.

You can also highlight a signal and its source or destination blocks. For details, see “Display Signal Sources and Destinations” on page 62-38.

Testing Signals

You can perform the following kinds of tests on signals:

- “Minimum and Maximum Values” on page 62-6
- “Connection Validation” on page 62-6

Minimum and Maximum Values

For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Signal Ranges” on page 62-41.

Connection Validation

Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities.

To detect signal compatibility errors before running a simulation, update the diagram.

Signal Groups

The `Signal Builder` block displays interchangeable groups of signal sources. Use the Signal Builder to create or edit groups of signals and to switch the groups into and out of a model.

Signal groups can help with testing a model, especially when you use them with Simulink `Assertion` blocks and the Model Coverage Tool in the Simulink Verification and Validation product.

For details, see “Signal Groups” on page 62-62.

Signal Types

In this section...
"Summary of Signal Types" on page 62-8
"Control Signals" on page 62-8
"Composite (Bus) Signals" on page 62-9

Summary of Signal Types

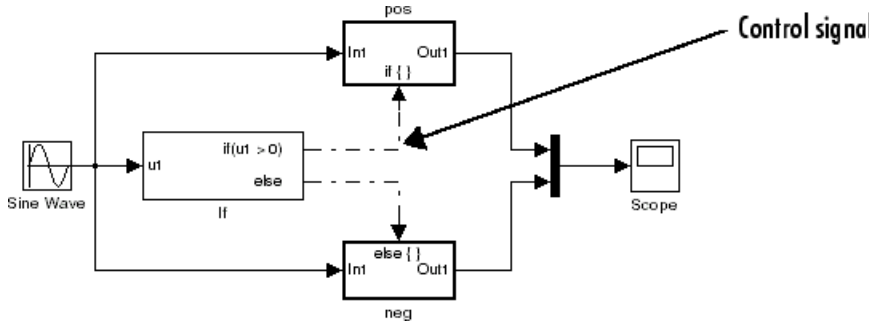
You can use many different kinds of signals in a model. The following table summarizes the signal types, and links to sections that describe each type in detail.

Signal Type	Description
Array of buses	An array whose elements are buses. See "Combine Buses into an Array of Buses" on page 63-91.
Bus (Composite)	A Simulink composite signal made up of other signals, optionally including other bus signals. See "Composite (Bus) Signals" on page 62-9.
Control	Signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem. For details, see "Control Signals" on page 62-8.
Nonvirtual	Signal that occupies its own storage. A nonvirtual bus reads inputs and writes outputs by accessing copies of the component signals.
Mux	A virtual vector created with a Mux block. See "Mux Signals" on page 62-11.
Variable-Size	Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.
Virtual	Signal that represents another signal or set of signals. A virtual signal is used for graphical purposes and has no functional effect. See "Virtual Signals" on page 62-11.

Control Signals

A *control signal* is a signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal.

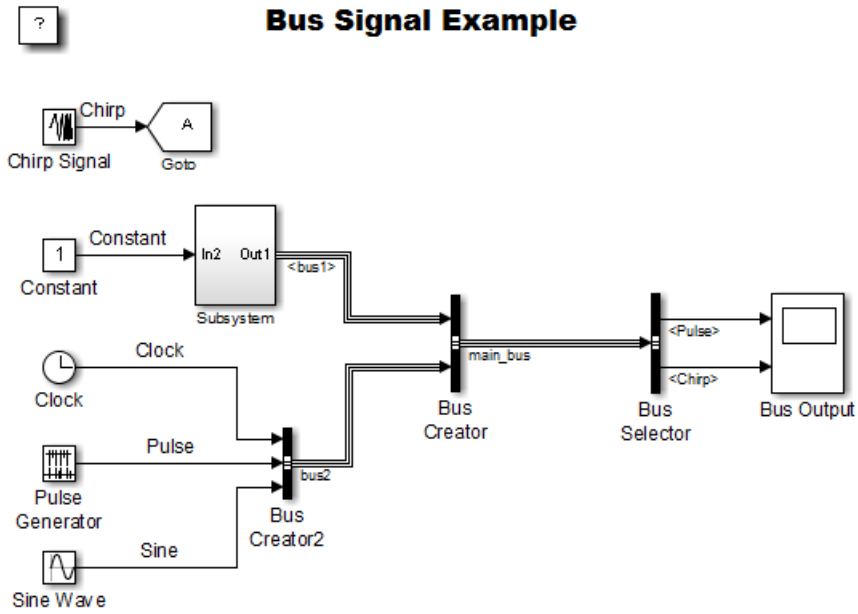
When you update or simulate a block diagram, Simulink uses a dash-dot pattern to redraw lines representing the control signals.



Composite (Bus) Signals

You can group multiple signals into a hierarchical composite signal, called a *bus*, route the bus from block to block, and extract constituent signals from the bus where needed. When you have many parallel signals, buses can simplify the appearance of a model and help to clarify generated code. A bus can be either virtual or nonvirtual.

For example, if you open and simulate the `Bus Signal` example model, the `bus1`, `bus2`, and `main_bus` signals are bus signals. These virtual bus signals use the triple line style.



For details, see “Composite Signals” on page 63-3.

Virtual Signals

In this section...
"About Virtual Signals" on page 62-11
"Mux Signals" on page 62-11

About Virtual Signals

A *virtual signal* is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; they have no mathematical or physical significance. Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as Bus Creator, can generate either virtual or nonvirtual signals.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Bus signals can also be virtual or nonvirtual. For details, see "Types of Simulink Buses" on page 63-7.

Mux Signals

A Simulink *mux* is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. A Simulink mux is not a hardware multiplexer, which combines multiple data streams into a single channel. A Simulink mux does not combine signals in any functional sense: it exists only virtually, and its only purpose is to simplify the visual appearance of a model. Using a mux has no effect on simulation or generated code.

You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux just as if the values existed in a contiguous vector, and the result is a contiguous vector, not a mux. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage.

The Simulink documentation refers, sometimes interchangeably, to “muxes”, “vectors”, and “wide signals”, and all three terms appear in Simulink GUI labels and API names. This terminology can be confusing, because most vector signals, which are also called wide signals, are nonvirtual and hence are not muxes. To avoid confusion, reserve the term “mux” to refer specifically to a virtual vector.

A mux is a *virtual* vector signal. The constituent signals of a mux retain their separate existence in every way, except visually. You can also combine scalar and vector signals into a *nonvirtual* vector signal, by using a `Vector Concatenate` block. The signal output by a Vector Concatenate block is an ordinary contiguous vector, inheriting no special properties from the fact that it was created from separate signals.

To create a composite signal whose constituent signals retain their identities and can have different data types, use a `Bus Creator` block rather than a Mux block. For details, see “Composite Signals” on page 63-3. Although you can use a Mux block to create a composite signal in some cases, MathWorks discourages this practice. See “Prevent Bus and Mux Mixtures” on page 63-123 for more information.

Using Muxes

The Signal Routing library provides two virtual blocks for implementing muxes:

`Mux`

Combine several input signals into a mux (virtual vector) signal

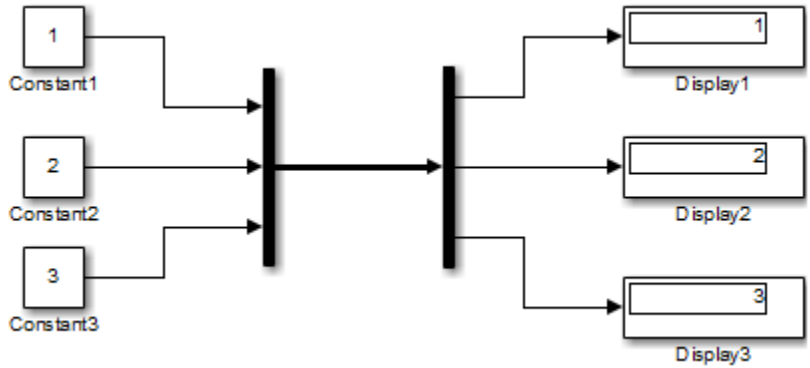
`Demux`

Extract and output the values in a mux (virtual vector) signal

To implement a mux signal:

1. Select a Mux and Demux block from the Signal Routing library.
2. Set the Mux block **Number of inputs** and the Demux block **Number of outputs** block parameters to the desired values.
3. Connect the Mux, Demux, and other blocks as needed to implement the desired signal.

The next figure shows three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.



The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name. In this example, the line connecting the blocks, representing the mux signal, is wide because the model has been built with **Display > Signals & Ports > Wide Nonscalar Lines** option enabled. See "Display Signal Attributes" on page 62-57 for details.

Signals input to a `Mux` block can be any combination of scalars, vectors, and muxes. The signals in the output mux appear in the order in which they were input to the Mux block. You can use multiple Mux blocks to create a mux in several stages, but the result is flat, not hierarchical, just as if the constituent signals had been combined using a single mux block.

The values in all signals input to a Mux block must have the same data type.

If a Demux block attempts to output more values than exist in the input signal, an error occurs. A Demux block can output fewer values than exist in the input mux, and can group the values it outputs into different scalars and vectors than were input to the Mux block. However, the Demux block cannot rearrange the order of those values. For details, see Demux.

Note: MathWorks discourages using Mux and Demux blocks to create and access buses under any circumstances. See "Prevent Bus and Mux Mixtures" on page 63-123 for details.

Signal Values

In this section...
“Signal Data Types” on page 62-15
“Signal Dimensions, Size, and Width” on page 62-15
“Complex Signals” on page 62-15
“Initializing Signal Values” on page 62-16
“Viewing Signal Values” on page 62-16
“Displaying Signal Values in Model Diagrams” on page 62-17
“Exporting Signal Data” on page 62-18

Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 57-2 for more information.

Signal Dimensions, Size, and Width

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as vectors and 2-D or multidimensional signals as matrices. A one-element array is frequently referred to as a scalar.

The size of a signal refers to the number of elements that a signal contains. The size of a matrix (2-D) signal is generally expressed as M-by-N, where M is the number of columns and N is the number of rows making up the signal. The size of a vector signal is referred to as the width of the signal.

For more information, see “Signal Dimensions” on page 62-30.

Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level `Inport` block.
- Create a `Constant` block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the `Real-Imag to Complex` conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

Initializing Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

Signal Data Type	Default Initial Value
Numeric (other than fixed-point)	Zero
Fixed-point	Ground value
Boolean	False
Enumerated	Default value

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as `Outport`, `Data Store Memory`, and `Memory`, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 62-47.

Viewing Signal Values

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either

the Scope block or the Signal & Scope Manager to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 25-8. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, see “Floating Scope and Scope Viewer Tasks” on page 25-65
- The Signal & Scope Manager, see “Signal and Scope Manager” on page 25-73
- Test points, which are signals that Simulink guarantees to be observable when using a `Floating Scope` block in a model, see “Test Points” on page 62-55.

Displaying Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 62-17
- “Display Signal Value After Simulation” on page 62-17

Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

1. In the Simulink Editor, select **Display > Data Display in Simulation**.
2. From the submenu, select either **Show Value Labels When Hovering** or **Show Value Labels When Clicked**.
3. To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 33-18.

Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

1. Right-click the signal.
2. In the context menu, select **Show Value Label of Selected Port**.

Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 59-4.

Signal Label Propagation

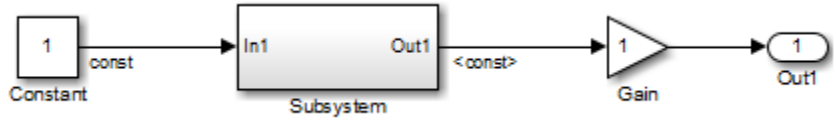
In this section...
“Propagated Signal Labels” on page 62-19
“Blocks That Support Signal Label Propagation” on page 62-19
“Display Propagated Signal Labels” on page 62-20
“How Simulink Propagates Signal Labels” on page 62-21

Propagated Signal Labels

When you enable the display of signal label propagation for output signals of the blocks listed in “Blocks That Support Signal Label Propagation” on page 62-19:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, `<sig1>`).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (`<>`) for the label.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (`<const>`) is based on the name of the upstream output signal of the Constant block (`const`).



For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 62-21.

Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function Call Split
- Goto
- Inport (subsystem only; not root inports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger
- Two-Way Connection (a Simscape block)

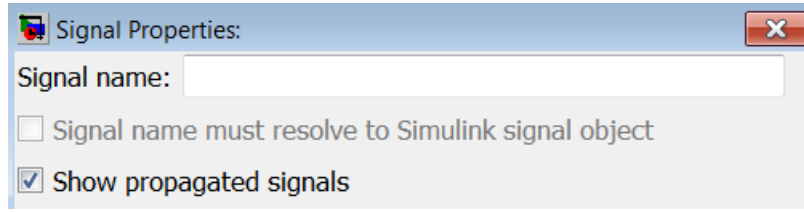
The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus signal, use the "Signal Hierarchy Viewer" on page 63-8.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see "Display Propagated Signal Labels" on page 62-20.

Display Propagated Signal Labels

To display a propagated signal label:

1. Set **Model Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** to `error`.
2. Right-click the signal for which you want to display a propagated signal label and select **Properties**.
3. In the Signal Properties dialog box, select **Show propagated signals**.



The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as `'on'`. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs,'FindAll','on','type','line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)

      %set(signalLines(i),'signalPropagation','off');
      set(signalLines(i),'signalPropagation','on');
end
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

1. In the model diagram, click the signal label.
2. Remove the label text.
3. In the signal label text box, enter an angle bracket (<).
4. Click outside the signal label.

   Simulink displays the propagated signal label.

How Simulink Propagates Signal Labels

Understanding how Simulink propagates signal labels helps you to:

- Anticipate the scope of the signal label propagation, from source to final destination
- Configure your model to display signal labels for the signals that you want

For output signals from supported blocks, you can choose to have Simulink display propagated signal labels. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 62-19.

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:

- "Processing for Referenced Models" on page 62-26
- "Processing for Variants and Configurable Subsystems" on page 62-28

General Signal Label Propagation Processing

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

1. Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
2. Stops when it encounters a block that either:
   - Supports signal label propagation and has a signal name
   - Does not support signal label propagation
3. Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
4. Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the `Out1` port).

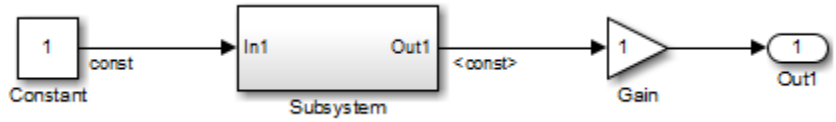
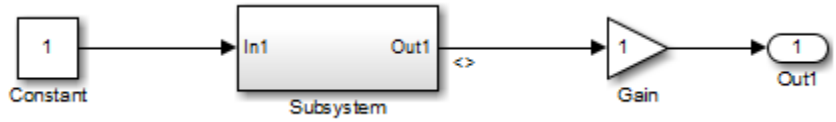
Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

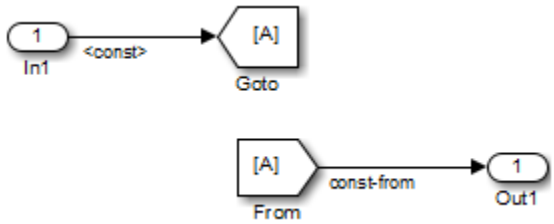
Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem output signal is `<const>`.



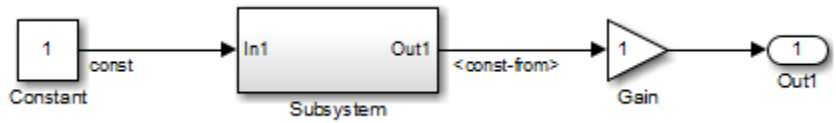
If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (<>).



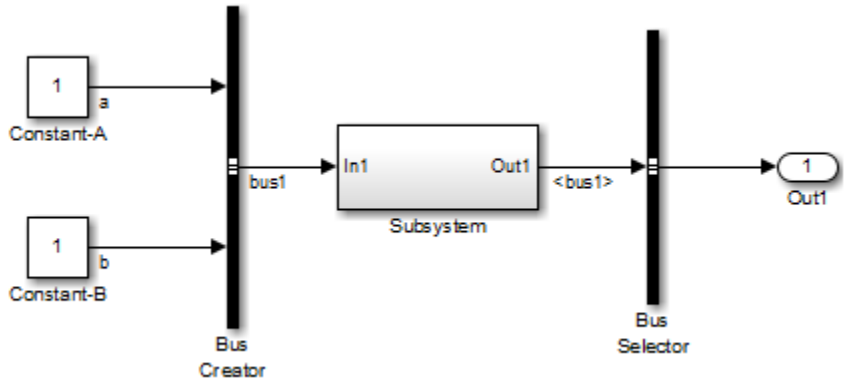
Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const-from` for the output signal of the From block, as shown below.



The propagated signal label for the Subsystem output signal changes to `<const-from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.



In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus signal of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (`a` and `b`).



Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in "Display Propagated Signal Labels" on page 62-20, use the default setting for the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for model reference variants have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

Signal Dimensions

In this section...
"About Signal Dimensions" on page 62-30
"Simulink Blocks that Support Multidimensional Signals" on page 62-31

About Signal Dimensions

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See "Multidimensional Arrays" for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals. To determine the signal dimensionality of a particular block, see the block documentation. See "Determine Output Signal Dimensions" on page 62-32 for information on what determines the dimensions of output signals for blocks that can output nonscalar signals.

Note: Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See "Variable-Size Signal Basics" on page 64-2.

Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

1. In the Simulink editor, from the **Help** menu, click **Simulink > Block Data Types & Code Generation Support > All Tables**.

   A separate window with the Simulink Block Data Type Support table opens.
2. In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An a **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

Determine Output Signal Dimensions

In this section...
“About Signal Dimensions” on page 62-32
“Determining the Output Dimensions of Source Blocks” on page 62-32
“Determining the Output Dimensions of Nonsource Blocks” on page 62-33
“Signal and Parameter Dimension Rules” on page 62-33
“Scalar Expansion of Inputs and Parameters” on page 62-34

About Signal Dimensions

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

Determining the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the `Constant` block and the `Sine Wave` block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block's **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how a source block's output value parameter(s) and **Interpret vector parameters as 1-D** parameter determine the dimensionality of its output, consider the Constant block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block's output.

Constant Value	Interpret vector parameters as 1-D	Output
scalar	off	one-element array
scalar	on	one-element array

Constant Value	Interpret vector parameters as 1-D	Output
1-by-N matrix	off	1-by-N matrix
1-by-N matrix	on	N-element vector
N-by-1 matrix	off	N-by-1 matrix
N-by-1 matrix	on	N-element vector
M-by-N matrix	off	M-by-N matrix
M-by-N matrix	on	M-by-N matrix

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

Determining the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in "Signal and Parameter Dimension Rules" on page 62-33).

Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see "Scalar Expansion of Inputs and Parameters" on page 62-34).

Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 62-34).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

Note You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.

Scalar Expansion of Inputs and Parameters

Scalar expansion is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to a block's inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For

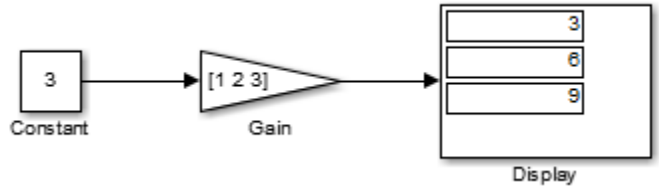
example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

Input(s)	Associated Block Parameter	Scalar Expansion
Scalar	Nonscalar	Input expanded to match parameter dimensions. See "Scalar Input and Nonscalar Parameter" on page 62-35.
Nonscalar	Scalar	Scalar parameter expanded to match number of elements of input. See "Nonscalar Input and Scalar Parameter" on page 62-36.
Combination of scalar and nonscalar	No corresponding parameter	Scalar inputs expanded to match dimensions of largest nonscalar input. See "Scalar and Nonscalar Inputs and No Associated Parameter" on page 62-36.

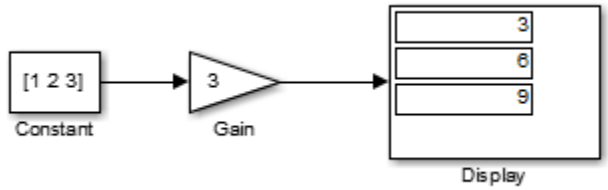
Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.



Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.



Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector `[3 3 3]`.

Display Signal Sources and Destinations

In this section...
“About Signal Highlighting” on page 62-38
“Highlighting Signal Sources” on page 62-38
“Highlighting Signal Destinations” on page 62-39
“Removing Highlighting” on page 62-40
“Resolving Incomplete Highlighting to Library Blocks” on page 62-40

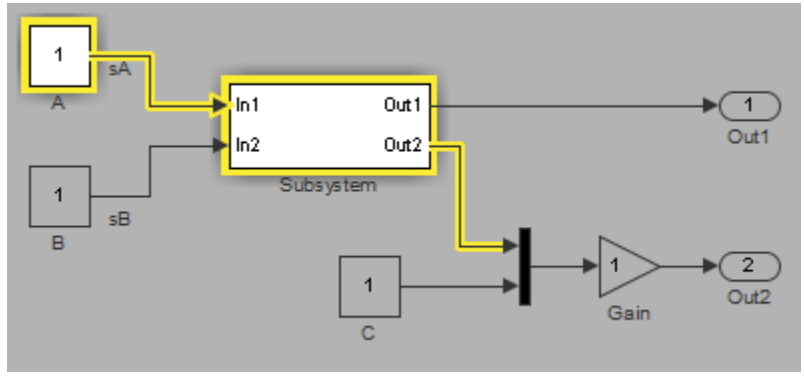
About Signal Highlighting

You can highlight a signal and its source or destination block(s), then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem boundaries, allowing you to trace a signal across multiple subsystem levels. Highlighting does not cross the boundary into or out of a referenced model. If a signal is composite, all source or destination blocks are highlighted. (See “Composite Signals” on page 63-3.)

Highlighting Signal Sources

To display the source block(s) of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that write the value of the signal

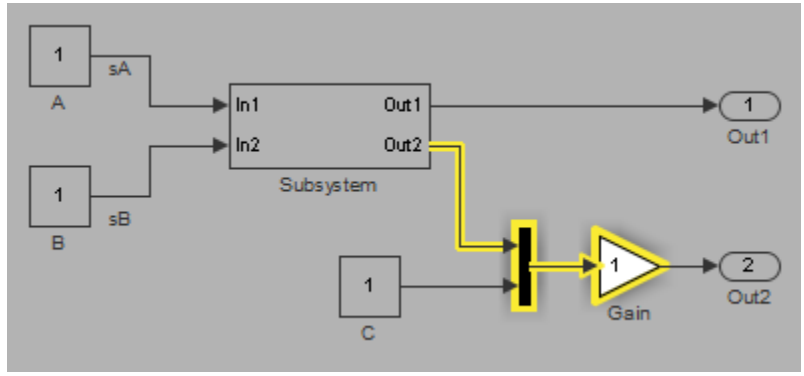


Highlighting Signal Destinations

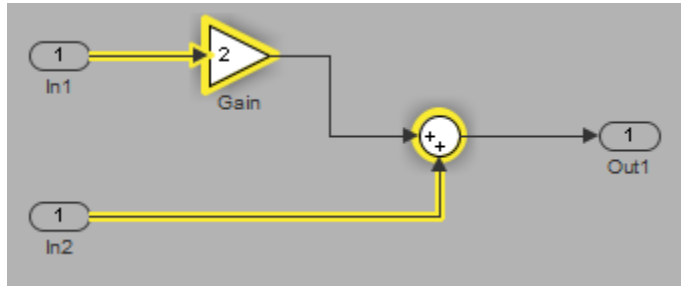
To display the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the inport block for the line that you select

In this example, the selected signal highlights the Gain block as the destination block.



In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate inport blocks.



Removing Highlighting

To remove all highlighting, select **Remove Highlighting** from the model's context menu, or select **Display > Remove Highlighting**.

Resolving Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, first update the diagram (for example, by pressing **Ctrl+D**). The update of the diagram resolves all library references and displays the complete path to a destination block or from a source block.

Signal Ranges

In this section...
“About Signal Ranges” on page 62-41
“Blocks That Allow Signal Range Specification” on page 62-41
“Specifying Ranges for Signals” on page 62-42
“Checking for Signal Range Errors” on page 62-43

About Signal Ranges

Many Simulink blocks allow you to specify a range of valid values for their output signals. Simulink provides a diagnostic that you can enable to detect when blocks generate signals that exceed their specified ranges during simulation. See the sections that follow for more information.

Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- `Abs`
- `Constant`
- `Data Store Memory`
- `Data Type Conversion`
- `Difference`
- `Discrete Derivative`
- `Discrete-Time Integrator`
- `Gain`
- `Inport`
- `Interpolation Using Prelookup`
- `1-D Lookup Table`
- `2-D Lookup Table`
- `n-D Lookup Table`
- `Math Function`
- `MinMax`

- `Multiport Switch`
- `Outport`
- `Product`, `Divide`, `Product of Elements`
- `Relay`
- `Repeating Sequence Interpolated`
- `Repeating Sequence Stair`
- `Saturation`
- `Saturation Dynamic`
- `Signal Specification`
- `Sum`, `Add`, `Subtract`, `Sum of Elements`
- `Switch`

Specifying Ranges for Signals

In general, use the **Output minimum** and **Output maximum** parameters that appear on a block parameter dialog box to specify a range of valid values for the block output signal. Exceptions include the `Data Store Memory`, `Inport`, `Outport`, and `Signal Specification` blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See "Blocks That Allow Signal Range Specification" on page 62-41 for a list of applicable blocks.

When specifying minimum and maximum values that constitute a range, enter only expressions that evaluate to a scalar, real number with `double` data type. The default values for the minimum and maximum are `[]` (unspecified). The scalar values that you specify are subject to expansion, for example, when the block inputs are nonscalar or bus signals (see "Scalar Expansion of Inputs and Parameters" on page 62-34).

Note: You cannot specify the minimum or maximum value as `NaN`, `inf`, or `-inf`.

Specifying Ranges for Complex Numbers

When you specify an **Output minimum** and/or **Output maximum** for a signal that is a complex number, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex

number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as `(sqrt(a^2+b^2))`

Checking for Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see "Specifying Ranges for Signals" on page 62-42) and the block data type. That is, Simulink performs the following check:

```
DataTypeMin ≤ MinValue ≤ VALUE ≤ MaxValue ≤ DataTypeMax
```

where

- `DataTypeMin` is the minimum value representable by the block data type.
- `MinValue` is the minimum value the block should output, specified by, e.g., **Output minimum**.
- `VALUE` is the signal value that the block outputs.
- `MaxValue` is the maximum value the block should output, specified by, e.g., **Output maximum**.
- `DataTypeMax` is the maximum value representable by the block data type.

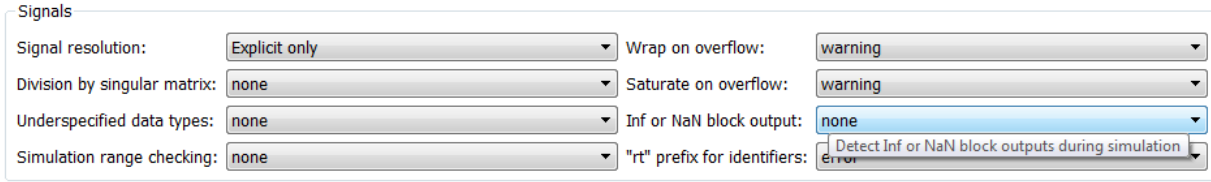
Note: It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

Enabling Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

1. In your model window, select **Simulation** > **Model Configuration Parameters**.

   Simulink displays the Configuration Parameters dialog box.
2. In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics** > **Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to `error` or `warning`.



3 Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See "Simulation range checking" for more information.

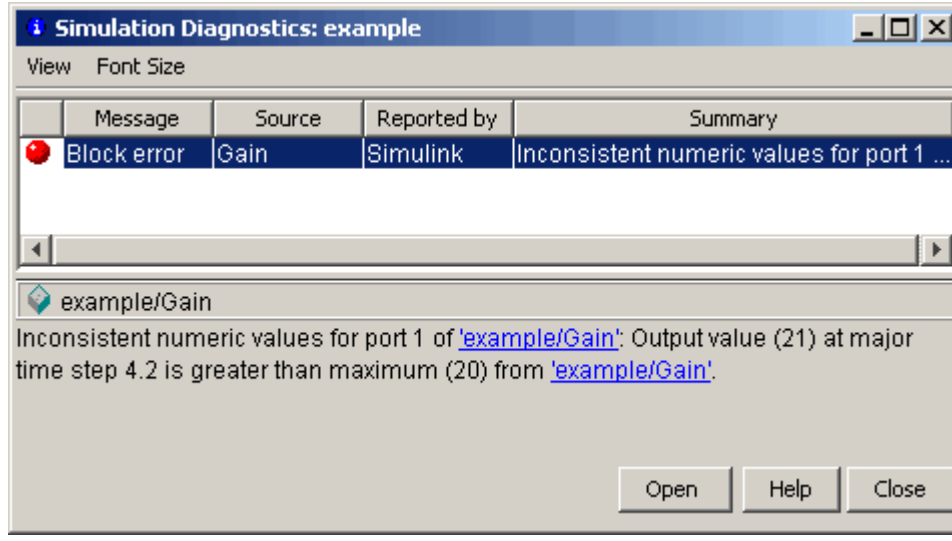
Simulating Models with Simulation Range Checking

To check for signal range errors or warnings:

1 Enable the **Simulation range checking** diagnostic for your model (see "Enabling Simulation Range Checking" on page 62-43).

2 In your model window, select **Simulation** > **Run** to simulate the model.

Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies `error`, Simulink stops the simulation and displays an error message:



Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies `warning`, Simulink displays a warning message in the MATLAB Command Window:

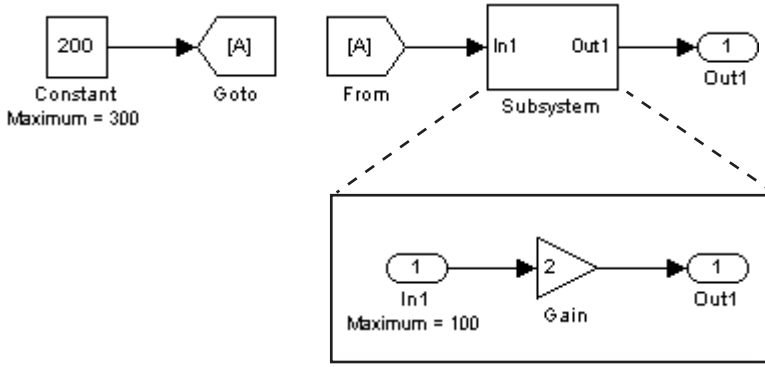
```
Warning: Inconsistent numeric values for port 1
of 'example/Gain': Output value (21) at major
time step 4.2 is greater than maximum (20) from
'example/Gain'.
```

Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

Signal Range Propagation for Virtual Blocks

Some virtual blocks (see "Nonvirtual and Virtual Blocks" on page 33-2) allow you to specify ranges for their output signals, for example, the `Inport` and `Outport` blocks. When the **Simulation range checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the *tightest* range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:



In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block.

Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink displays the following error message:

Initialize Signals and Discrete States

In this section...
"About Initialization" on page 62-47
"Using Block Parameters to Initialize Signals and Discrete States" on page 62-48
"Use Signal Objects to Initialize Signals and Discrete States" on page 62-48
"Using Signal Objects to Tune Initial Values" on page 62-50
"Example: Using a Signal Object to Initialize a Subsystem Output" on page 62-51
"Initialization Behavior Summary for Signal Objects" on page 62-52

About Initialization

Note: For information about initializing bus signals, see "Specify Initial Conditions for Bus Signals" on page 63-78.

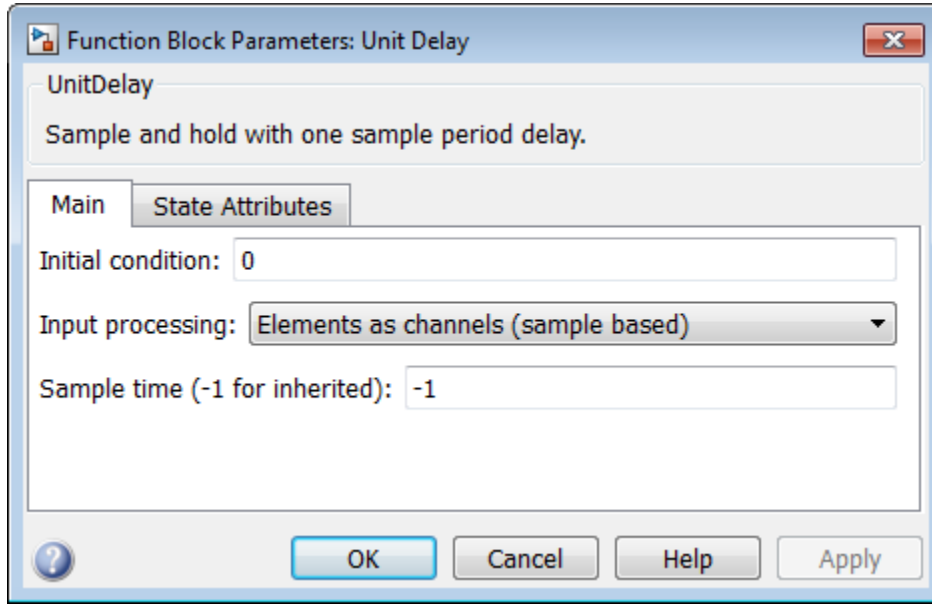
Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., `Outport`, `Data Store Memory`, or `Memory`, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent.

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in "Symbol Resolution" on page 4-97.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the `Merge` block.

Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.



Use Signal Objects to Initialize Signals and Discrete States

You can use signal objects that have a storage class other than `'auto'` or `'SimulinkGlobal'` to initialize

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

1 Create the signal object.

On the Model Explorer toolbar, select **Add** > **Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as `S1`. Alternatively, use this command at the command prompt:

```
S1 = Simulink.Signal;
```

The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see "Create Data Objects for a Model Using Data Object Wizard" on page 57-61 in the Simulink documentation.

2. Set the signal object's storage class to a value other than `auto` or `SimulinkGlobal`. In the Model Explorer **Contents** pane, select the signal object. In the Dialog pane, set **Storage class** to `ExportedGlobal`. Alternatively, use this command at the command prompt:

   ```
   S1.CoderInfo.StorageClass = 'ExportedGlobal';
   ```

3. Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

   The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

   In the Model Explorer Dialog pane, set **Initial value** to `0.5`. Alternatively, use this command at the command prompt:

   ```
   S1.InitialValue = '0.5'
   ```

   If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty ([ ]) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses

the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

Classic initialization mode: In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as `[]`):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

Simplified initialization mode: In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

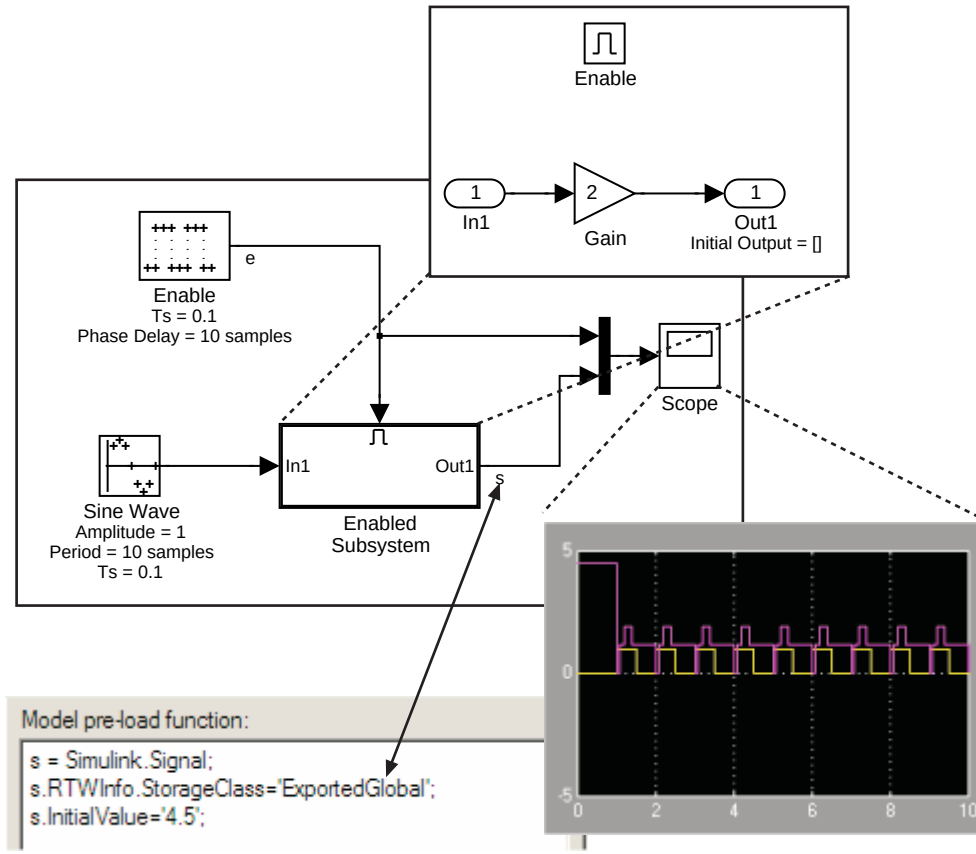
Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object's initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a `Memory` block state named `M1`. To do this, you might create a signal object named `M1`, set its storage class to `'ExportedGlobal'`, set its initial value to `K (M1.InitialValue='K'`), where `K` is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the Memory block to `[]` to avoid consistency errors. You could then change the initial value of the Memory block's state any time during the simulation by changing the value of `K` at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

Example: Using a Signal Object to Initialize a Subsystem Output

The following example shows a signal object specifying the initial output of an enabled subsystem.

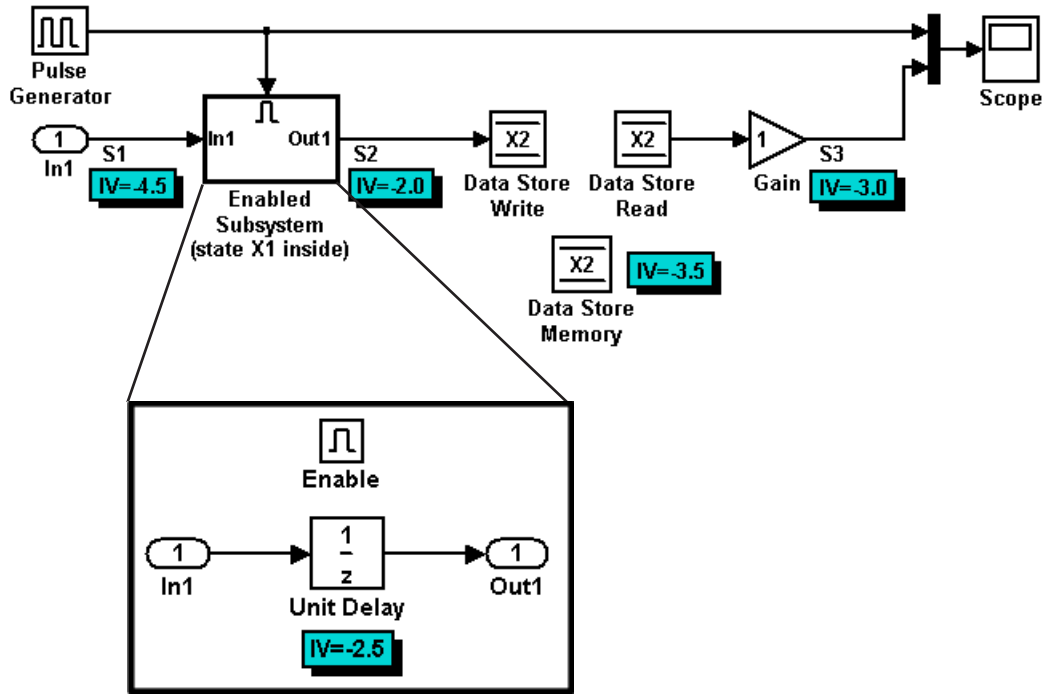


Signal `s` is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem's Outport block must be `[ ]` or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 57-71.

Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.



Signal or Discrete State	Description	Behavior
S1	Root inport	• Initialized to `S1.InitialValue`. • If you use the **Data Import/Export** pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.
X1	Unit Delay block — Block with a discrete state that	• Initialized to `X1.InitialValue`. • Simulink checks whether `X1.InitialValue` matches the initial condition specified for the block and displays an error if a mismatch occurs.

Signal or Discrete State	Description	Behavior
	has an initial condition	• At first write, the output equals `X1.InitialValue` and the state equals `S1`. • At each time step after the first write, the output equals the state and the state is updated to equal `S1`. • If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem's Enable block parameter **States when enabling** is set to `reset`.
X2	Data Store Memory block	• Data type work (DWork) vector initialized to `X2.InitialValue`. For information on work vectors, see "DWork Vector Basics". • Simulink checks whether `X2.InitialValue` matches the initial condition specified for the block, and displays an error if a mismatch occurs. • Data Store Write blocks overwrite the value.
S2	Output of an enabled subsystem	• Initialized to `S2.InitialValue` or the value of the Outport block. If multiple initial values are specified for the same signal, all initial values must be the same. • The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value. • The initial value is also used as a reset value if the subsystem's Enable block parameter **States when enabling** or Outport block parameter **Output when disabled** is set to `reset`.
S3	Persistent signals	• Initialized to `S3.InitialValue`. • The output value is reset by the block at each time step. • Affects code generation only. For simulation, setting the initial value for `S3` is irrelevant because the values are overwritten at the model's simulation start time.

Test Points

In this section...
"What Is a Test Point?" on page 62-55
"Designating a Signal as a Test Point" on page 62-55
"Displaying Test Point Indicators" on page 62-56

What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a `Floating Scope` block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see "Signal storage reuse") and block reduction (see "Implement logic signals as Boolean data (vs. double)"). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see "Algebraic Loops" on page 3-38).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see "Signals with Test Points".

Marking a signal as a test point has no impact on signal logging that uses the `Dataset` logging format. For information about logging signals, see "Export Signal Data Using Signal Logging" on page 59-56.

Designating a Signal as a Test Point

Use one of the following ways to designate a signal as a test point:

- Open the signal's **Signal Properties** dialog and check **Test Point** in the **Logging and accessibility** section.
- Resolve the signal to a base workspace `Simulink.Signal` object whose storage class is `SimulinkGlobal`.

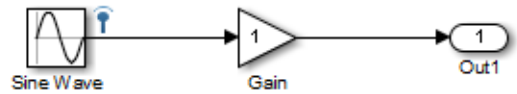
The second method is more convenient when you want to control test pointing without having to alter the model.

Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals `s2` and `s3` are test points:

Note: Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

A signal that is a test point can also be logged. See "Export Signal Data Using Signal Logging" on page 59-56 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.



To turn display of test point indicators on or off, in the Simulink Editor, select or clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

Display Signal Attributes

In this section...
"Ports & Signals Menu" on page 62-57
"Port Data Types" on page 62-58
"Design Ranges" on page 62-58
"Signal Dimensions" on page 62-59
"Signal to Object Resolution Indicator" on page 62-59
"Wide Nonscalar Lines" on page 62-60

Ports & Signals Menu

The **Display > Signals & Ports** submenu of the Simulink Editor offers the following options for displaying signal properties on the block diagram:

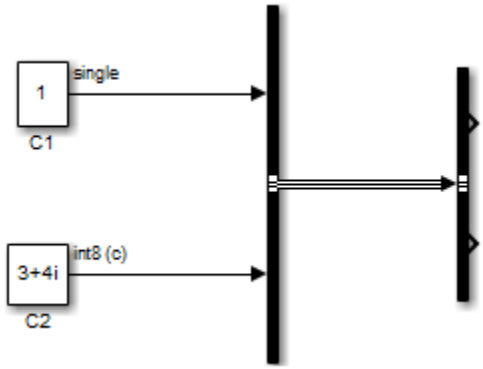
- Linearization Indicators
- Port Data Types (See "Port Data Types" on page 62-58)
- Design Ranges (See "Design Ranges" on page 62-58)
- Signal Dimensions (See "Signal Dimensions" on page 62-59)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See "Signal to Object Resolution Indicator" on page 62-59)
- Viewer Indicators
- Wide Nonscalar Lines (See "Wide Nonscalar Lines" on page 62-60)

In addition, you can display sample time information. If you first select **Display > Sample Time**, a submenu provides the choices of **Colors**, **Annotations** and **All**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Annotations** option provides black codes on the signal lines which indicate the type of sample time. **All** causes both the colors and the annotations to display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time

rate. If **Colors** is turned 'on', color codes also appear in the legend. The same is true if **Annotations** are turned 'on'.

Port Data Types

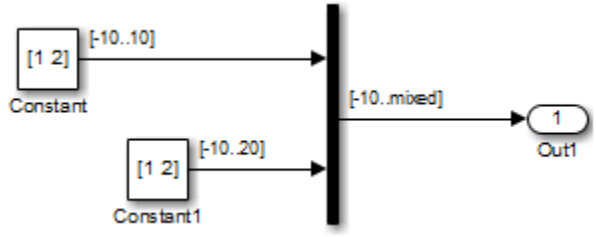
Displays the data type of a signal next to the output port that emits the signal.



The notation `(c)` following the data type of a signal indicates that the signal is complex.

Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.



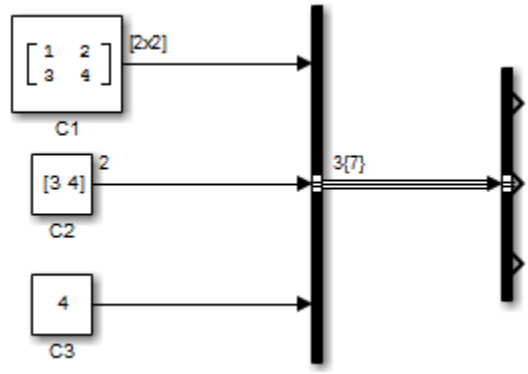
Ranges are displayed in the format `[min..max]`. In the above example, the design range at the output port of the Mux block is displayed as `[-10..mixed]`, because the two

signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see "Common Block Properties".

Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.



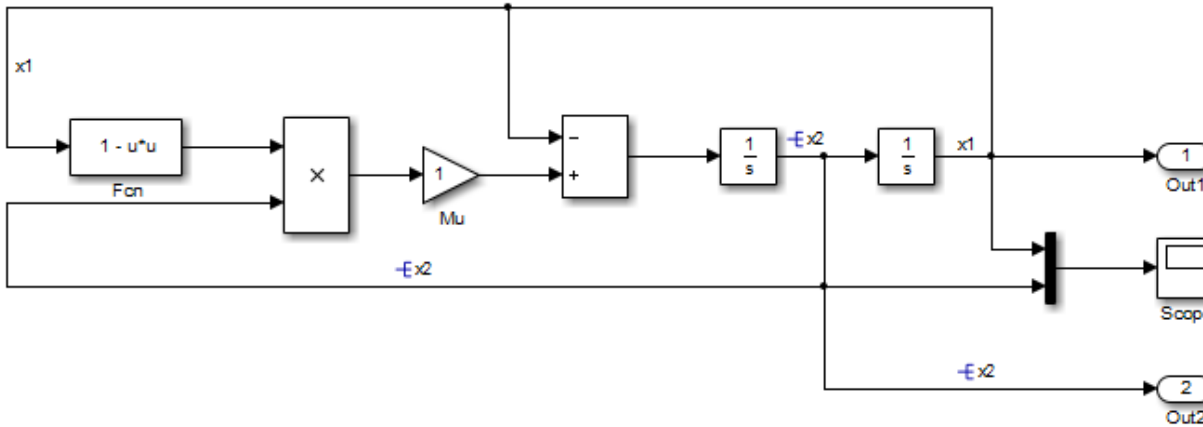
The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as `[`N_1`x`N_2`]` where N_i is the size of the `i`th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays `N{M}` where `N` is the number of signals carried by the bus and `M` is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements `{M}`.

Signal to Object Resolution Indicator

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that a signal's **Signal name must resolve to signal object** property is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal `x2` must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

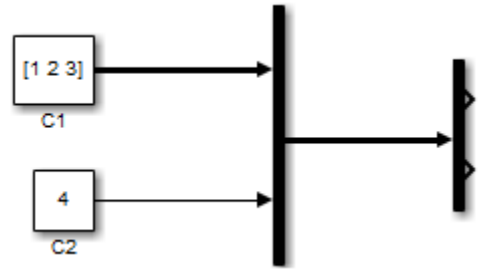


To suppress the display of signal resolution icons, in the model window deselect **Display > Signals & Ports > Signal to Object Resolution Indicator**, which is selected by default. To restore signal resolution icons, reselect **Signal to Object Resolution Indicator**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 4-97
- “Initialize Signals and Discrete States” on page 62-47
- Simulink.Signal

Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.



See “Composite Signals” on page 63-3 for more information about vector and matrix signals.

“Simulating with Signal Groups” on page 62-110
“Simulation Options Dialog Box” on page 62-111

About Signal Groups

The `Signal Builder` block displays and allows you to create or edit interchangeable groups of signal sources and quickly switch the groups into and out of a model.

Signal groups can greatly facilitate testing a model, especially when you use them with conjunction with Simulink `Assertion` blocks and the Model Coverage Tool from the Simulink Verification and Validation. For a description of the Model Coverage Tool, see “Model Coverage Collection Workflow”.

Model Configuration Parameter **Solver** pane settings can affect the Signal Builder block output. See “Simulation Phases in Dynamic Systems” on page 3-17 and “Solvers” on page 3-21 for a description of how solvers affect simulation.

Using the `Signal Builder` Block with Fast Restart

After you turn on fast restart:

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
  - Import signals or signal groups

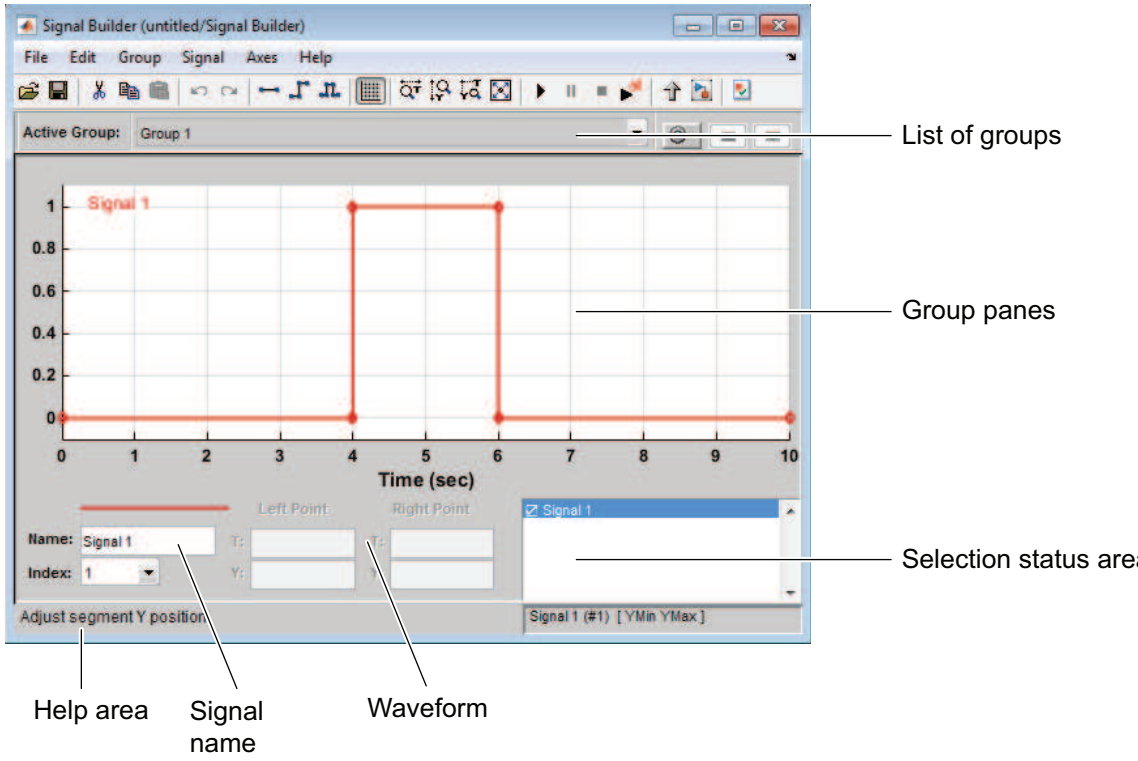
- Change signal output settings

- You can click the **Run all** button once. To reenable the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

Signal Builder Window

The Signal Builder block window allows you to define the shape of the signals (waveform) output by the block. You can specify any waveform that is piecewise linear.

To open the window, double-click the block. The Signal Builder window appears.



The Signal Builder window allows you to create and modify signal groups represented by a Signal Builder block. The Signal Builder window includes the following controls.

Group Pane

Displays the set of interchangeable signal source groups represented by the block. The pane for each group displays an editable representation of each waveform in the group. The name of the group appears at the top of the pane. Only one pane is visible at a time. To display a group that is not visible, from the list, select the group name. The block outputs the group of signals whose pane is currently visible. Each pane occupies a pane in the Signal Builder block dialog box.

Signal Axes

The signals appear on separate axes that share a common time range (see "Signal Builder Time Range" on page 62-108). This presentation allows you to compare the relative timing of changes in each signal. The Signal Builder automatically scales the range of each axis to accommodate the signal that it displays. Use the Signal Builder **Axes** menu to change the time (T) and amplitude (Y) ranges of the selected axis.

Signal List

Displays the names and visibility (see "Editing Signals" on page 62-66) of the signals that belong to the currently selected signal group. Clicking an entry in the list selects the signal. Double-clicking a signal entry in the list hides or displays the waveform on the group pane.

Selection Status Area

Displays the name of the currently selected signal and the index of the currently selected waveform segment or point.

Waveform Coordinates

Displays the coordinates of the currently selected waveform segment or point. You can change the coordinates by editing the displayed values (see "Editing Waveforms" on page 62-103).

Name

Name of the currently selected signal. You can change the name of a signal by editing this field (see "Renaming a Signal" on page 62-72).

Index

Index of the currently selected signal. The index indicates the output port at which the signal appears. An index of 1 indicates the topmost output port, 2 indicates the second

port from the top, and so on. You can change the index of a signal by editing this field (see "Changing a Signal Index" on page 62-75).

Help Area

Displays context-sensitive tips on using Signal Builder window features.

Editing Signal Groups

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

Creating and Deleting Signal Groups

To create a signal group:

1. In Signal Builder, copy an existing signal group.
2. Modify it to suit your needs.

To copy an existing signal group:

1. In Signal Builder, select the group from the list.
2. Select **Group > Copy**.

   A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

Renaming Signal Groups

To rename a signal group:

1. In Signal Builder, select the group from the list,
2. Select **Group > Rename**.

   A dialog box appears.
3. Edit the existing name in the dialog box or enter a new name. Click **OK**.

Moving Signal Groups

To reposition a group in the stack of group panes:

1. In Signal Builder, select the pane.
2. To move the group lower in the stack, select **Group > Move Down**.
3. To move the pane higher in the stack, select **Group > Move Up**.

Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

Creating Signals

To create a signal in the currently selected signal group:

1. In Signal Builder, from the Active Group list, select the group you want to add the signal to.
2. Select **Signal** > **New**.

   The menu lists the waveforms you can add (described in the table).

Waveform	Description	Inputs
Constant	Constant waveform	None.
Step	Step waveform	None.
Pulse	Pulse waveform	None.
Square	Square waveform	• **Frequency** Waveform frequency, in hertz • **Amplitude** Waveform amplitude • **Offset** Waveform vertical offset • **% Duty cycle** Percent of the period the signal is positive (a value between 0 and 100)
Triangle	Triangle waveform	• **Frequency** Waveform frequency, in hertz. • **Amplitude** Waveform amplitude

Waveform	Description	Inputs
		• **Offset** Waveform vertical offset
Sampled Sin	Sampled sinewave waveform	• **Frequency (Hz)** Waveform frequency, in hertz • **Amplitude** Waveform amplitude • **Offset** Waveform vertical offset • **Samples Per Period** Number of samples per waveform period
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency	• **Frequency** Waveform frequency, in hertz • **Mean** The mean value of the random variable output • **Standard Deviation** The standard deviation squared of the random variable output • **Seed (empty to use current state)** The initial seed value for the random number generator

Waveform	Description	Inputs
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency	• **Frequency** Frequency with which waveform fluctuates between **Upper value** and **Lower value**, in hertz • **Upper value** Upper limit of signal • **Lower value** Lower limit of signal • **Seed** The initial seed value for the random number generator
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1	• **Avg rate (1/sec)** Average rate of transition between 0 and 1 • **Seed (empty to use current state)** The initial seed value for the random number generator

Waveform	Description	Inputs
Custom	Custom piecewise linear waveform; custom values must fit within the display area	• **Time values** Vector of two or more time coordinates • **Y values** Vector of two or more signal amplitudes that correspond to the values in **Time values** The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length. **Note:** Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).

3. Select the waveform you want to add.
4. Specify the inputs (in prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

1. In the MATLAB Command Window, create data for two variables, *t* and *y*.

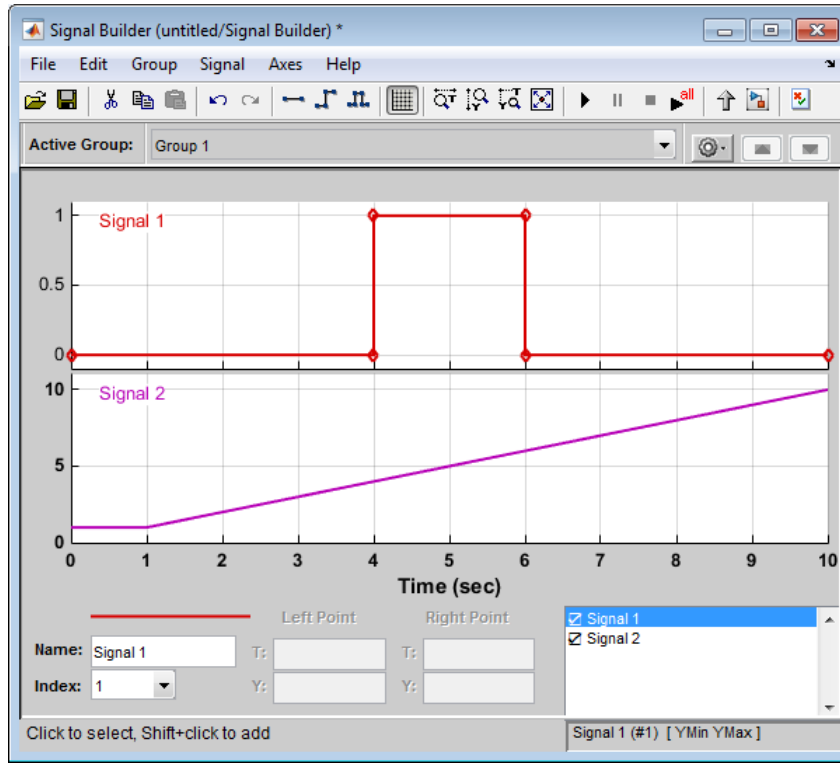
   ```
   t = 1:10
   y = 1:10
   ```

   These vectors must be the same size.
2. Create a model and add a Signal Builder block.
3. Double-click the Signal Builder block.

4 Select **Signal** > **New** > **Custom**.

5 In the Custom Waveform window, enter *t* in the **Time values** field and *y* in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.



Defining Signal Output

To specify the type of output to use for sending test signals:

1 In Signal Builder, select **Signal** > **Output**.

2 From the list, select:

- **Ports**

Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

  Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

Tip

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
- The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the `Bus Selector` block to select the signals from this bus.
- If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.

Copying and Pasting Signals

To copy a signal from one group and paste it into another group as a new signal:

1. In Signal Builder, select the signal you want to copy.
2. Select **Edit** > **Copy**.
3. Select the group you want to paste the signal into.
4. Select **Edit** > **Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

1. Select the signal you want to copy.
2. Select **Edit** > **Copy**.
3. Select the signal on the axis that you want to update.
4. Select **Edit** > **Paste**.

Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each

signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

Renaming a Signal

To rename a signal:

1. In Signal Builder, select **Signal** > **Rename**.

   A dialog box appears with an edit field that displays the current name of the signal.
2. Edit or replace the current name with a new name.
3. Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Replacing a Signal

To replace a signal:

1. In Signal Builder, select the signal, then select **Signal** > **Replace with** .

   A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.
2. Select one of the waveforms.

   If you select a standard waveform, the Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

Waveform	Description	Inputs
Constant	Constant waveform.	None.
Step	Step waveform.	None.
Pulse	Pulse waveform.	None.
Square	Square waveform.	• **Frequency** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude.

Waveform	Description	Inputs
		• **Offset** Waveform vertical offset. • **% Duty cycle** Percent of the period in which the signal is positive. Enter a value between 0 and 100.
Triangle	Triangle waveform.	• **Frequency** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude • **Offset** Waveform vertical offset.
Sampled Sin	Sampled sinewave waveform.	• **Frequency (Hz)** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude • **Offset** Waveform vertical offset. • **Samples Per Period** Number of samples per waveform period.

Waveform	Description	Inputs
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency.	• **Frequency** Waveform frequency, in Hertz. • **Mean** The mean value of the random variable output. • **Standard Deviation** The standard deviation squared of the random variable output. • **Seed (empty to use current state)** The initial seed value for the random number generator.
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency.	• **Frequency** Frequency with which waveform fluctuates between **Upper value** and **Lower value**, in Hertz. • **Upper value** Upper limit of signal. • **Lower value** Lower limit of signal. • **Seed** The initial seed value for the random number generator

Waveform	Description	Inputs
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1.	• **Avg rate (1/sec)** Average rate of transition between 0 and 1. • **Seed (empty to use current state)** The initial seed value for the random number generator
Custom	Custom piecewise linear waveform. Custom values must fit within the display area.	• **Time values** Vector of two or more time coordinates. • **Y values** Vector of two or more signal amplitudes that correspond to the values in **Time values**. The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length. **Note:** Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Changing a Signal Index

To change a signal index:

1. In Signal Builder, select the signal, then select **Signal > Change Index**.

   A dialog box appears with a drop-down list field containing the existing index of the signal.

2. From the drop-down list, another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

1. In Signal Builder, select the waveform, then select **Signal > Hide**.
2. To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
3. Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list (see "Signal List" on page 62-64).

Creating Signal Group Sets

You can create signal groups in the `Signal Builder` block by:

- "Creating Signal Group Sets Manually" on page 62-76
- "Importing Signal Group Sets" on page 62-77
- "Importing Data with Custom Formats" on page 62-102

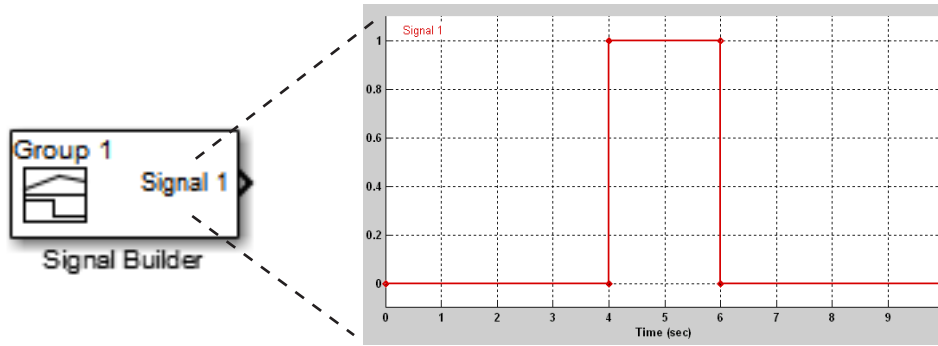
You can also use the `signalbuilder` function to populate the Signal Builder block.

Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in "Importing Signal Group Sets" on page 62-77.

To create an interchangeable set of signal groups:

1. Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.



By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

2 Use the block signal editor (see "Signal Builder Window" on page 62-63) to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

Note: Each signal group must contain the same number of signals.

3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, `Signal Builder` block requires the end times of signals within a group to match. If a mismatch occurs, `Signal Builder` block matches the end times by holding the last value of the signal with the smaller end time.

See "Simulating with Signal Groups" on page 62-110 for information on using signal groups in a model.

Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See "Importing

Signal Groups from Existing Data Sets" on page 62-78 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file `3Grp_3Sig.xls` in the folder *`matlabroot`*`\help\toolbox\simulink\ug\examples\signals` (open).

Signal Builder accepts signals only of type double.

Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File** > **Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

Note: You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (`.xls`, `.xlsx`)
- Comma-separated value (CSV) text files (`.csv`)
- MAT-files (`.mat`)

Note: Signal Builder block uses the `xlsread` function. See the `xlsread` documentation for information on supported platforms.

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where # increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

	Time	DC In	Trigger	AC In
2	0	1	2	3
3	1	2	3	4
4	2	3	4	5
5	3	4	5	6
6	4	5	6	7
7	5	6	7	8
8	6	7	8	9
9	7	8	9	10
10	8	9	10	11
11	9	10	11	12
12	10	11	12	13
13	11	12	13	14
14	12	13	14	15
15	13	14	15	16
16	14	15	16	17
17	15	16	17	18

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where # increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the Simulink.SimulationData.Dataset object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled:

  - `time`
  - `data`
  - `sigName`
  - `groupName`

  `sigName` and `groupName` are optional.
- For backwards compatibility, the Signal Builder block supports logged data from the `Simulink.ModelDataLogs` object and interprets this data as a single group. The `ModelDataLogs` format will be removed in a future release.
- Signal Builder block does not support:

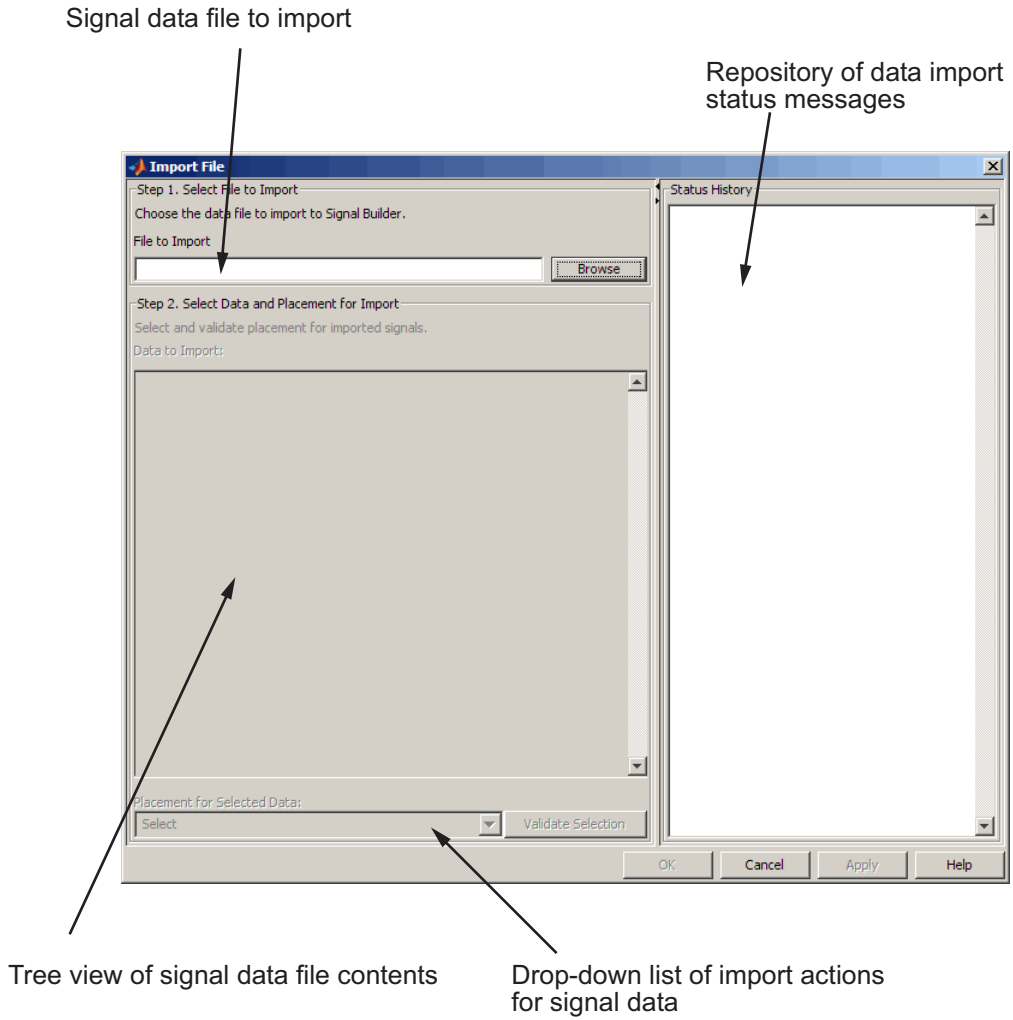
  - Simulink output as only a structure
  - Simulink output as only an array

Note: Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

Signal Builder Block Import File Dialog Box

The Signal Builder Import File dialog box allows you to import existing signal data files into the Signal Builder block.



Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

1. Create a model and drag a Signal Builder block into that model.
2. Double-click the block.

The Signal Builder window appears with its default Signal 1.

3 In Signal Builder, select **File** > **Import from File**.

The Import File dialog box appears.

4 In the **File to Import** field, enter a signal data file name or click **Browse**.

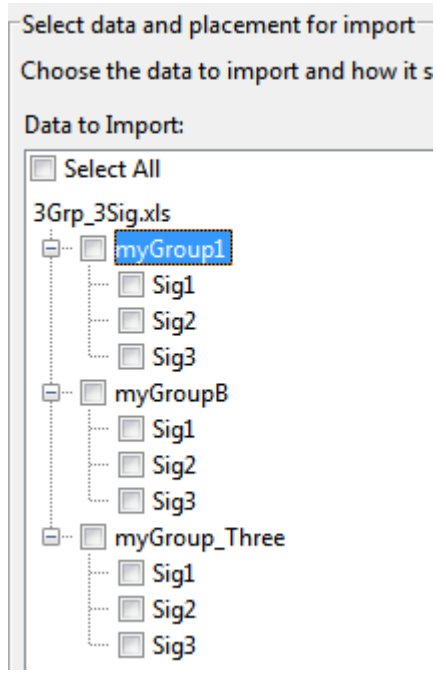
The file browser appears.

5 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note: If you try to import an improperly formatted data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays a more detailed error message (if there is one). For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.



6 Select the signals you want to import. To import all the signals, click **Select All**.

7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Replace existing dataset`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the status. For example:

```
Current data in Signal Builder will be replaced
by new data.
Number of groups: 3
Group name(s):
  myGroup1
  myGroupB
  myGroup_Three

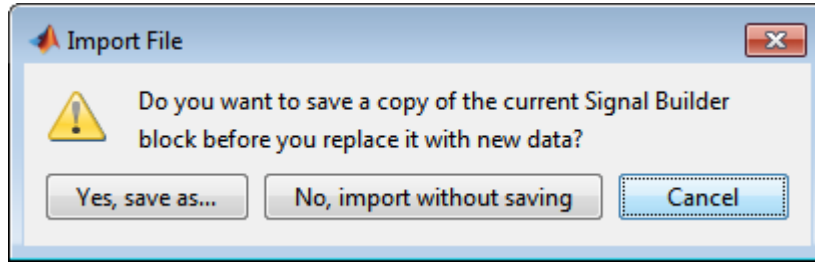
Number of signals per group: 3
Signal name(s):
  Sig1
  Sig2
  Sig3

(Names may have been renamed for uniqueness.)
.....................
```

The confirmation also enables the **OK** and **Apply** buttons.

9 If you are satisfied with the status message, click **Apply** to replace the existing signal data with the contents of this file.

When selecting `Replace existing dataset`, the software gives you the opportunity to save the existing contents of the Signal Builder block.



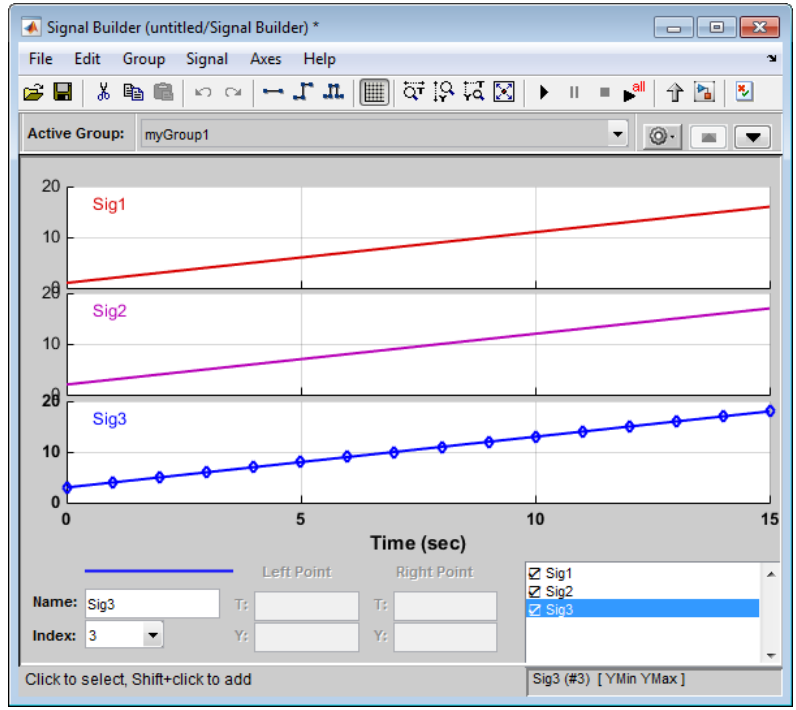
10 Click a button, as follows:

To...	Click...
Save the contents of the Signal Builder block before replacing it with the new signal data.	**Yes, save as**

To...	Click...
Note: This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content.	
Replace the contents of the Signal Builder block without saving them first.	**No, import without saving**
Stop the replacement process.	**Cancel**

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.



12 Click **OK**.

13 Inspect the updated Signal Builder window to confirm that your signal data is intact.

14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 62-83.

1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

   The Signal Builder window appears.
3. In the Signal Builder window, select **File** > **Import from File**.

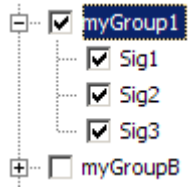
   The Import File dialog box appears.
4. In the **File to Import** field, enter a signal data file name or click **Browse**.

   The file browser is displayed.
5. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note: If you try to import an improperly formatted signal data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

   The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.
6. Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.

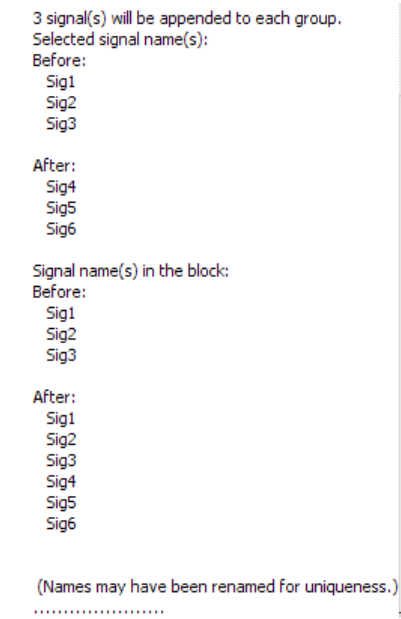


7. From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Append selected signals to all groups`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

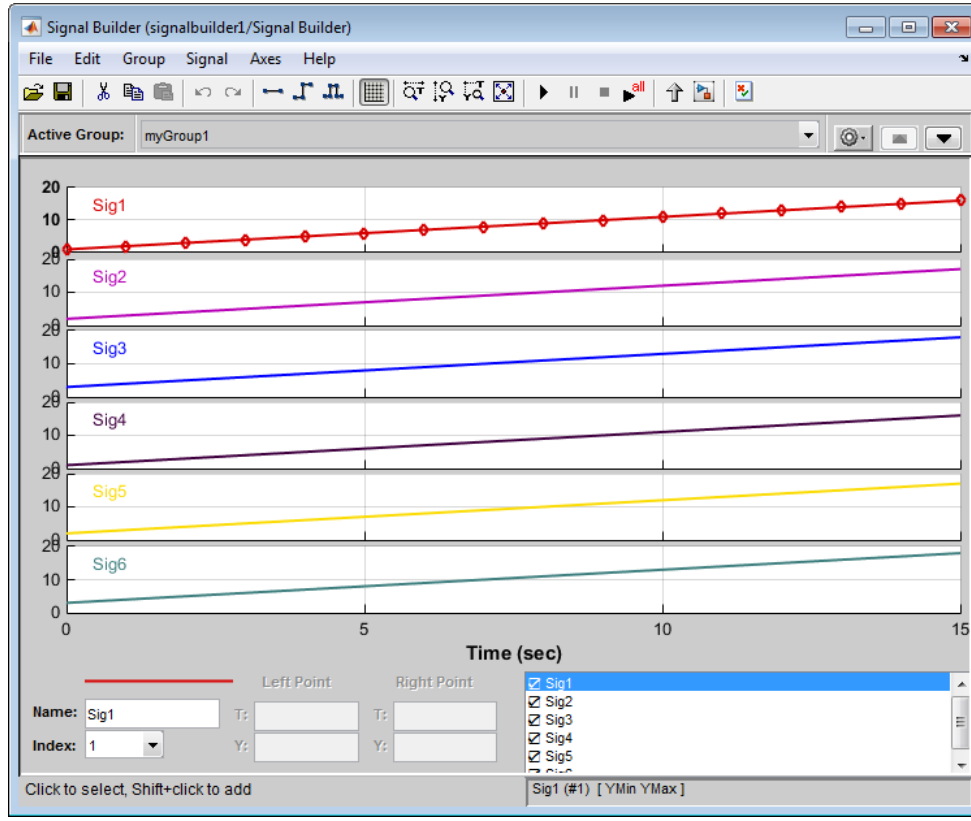


The confirmation also enables the **OK** and **Apply** buttons.

Observe the **Before** and **After** headings for the signals. These sections indicate the names of the block and imported data signals before and after the append action.

9 If you are satisfied with the status message, click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.

10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.



11 Click **OK**.

12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.

13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

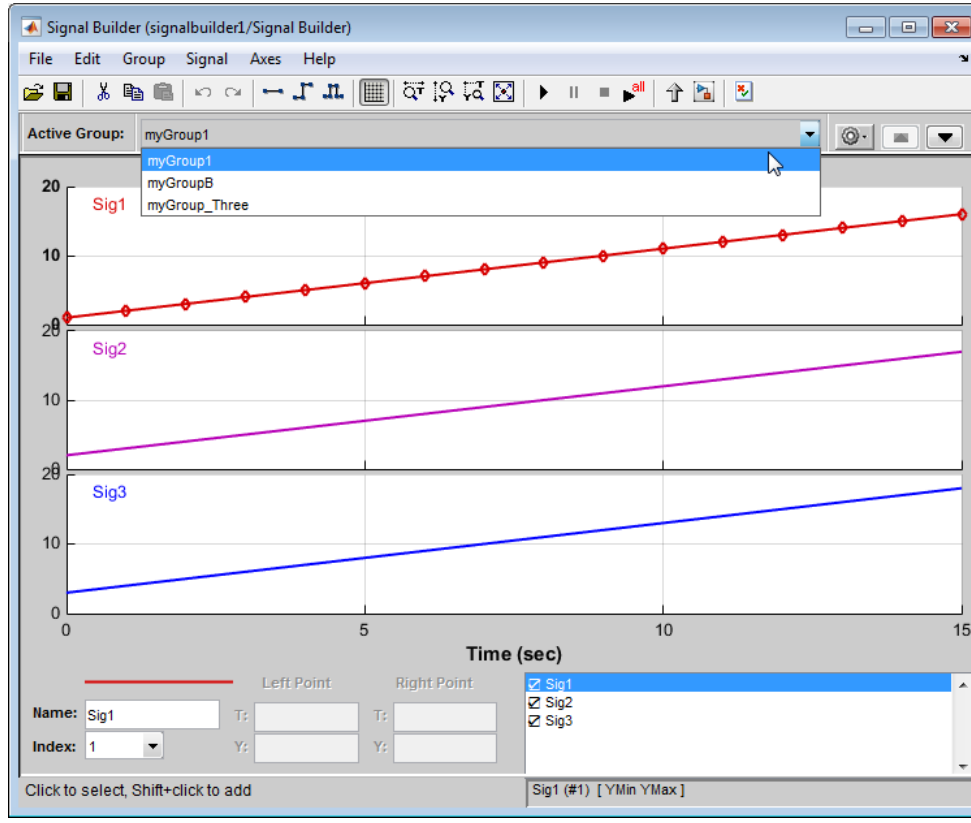
Appending Selected Signals to Sequential Existing Signal Groups

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

This topic uses `signalbuilder1` from the procedure in "Replacing All Signal Data with Selected Data" on page 62-83.

1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

   The Signal Builder window appears.
3. Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, myGroup1, myGroupB, and myGroup_Three.



4. In the Signal Builder window, select **File** > **Import from File**.

   The Import File dialog box appears.
5. In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

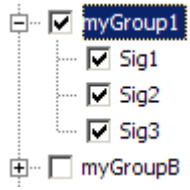
6 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note: If you try to import an improperly formatted signal data file, an error message popup window. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.



8 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Append selected signals to different groups (in order)`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

9 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
 1 signal will be appended to each group.
Selected signal names:
Before:
  Sig1
  Sig2
  Sig3

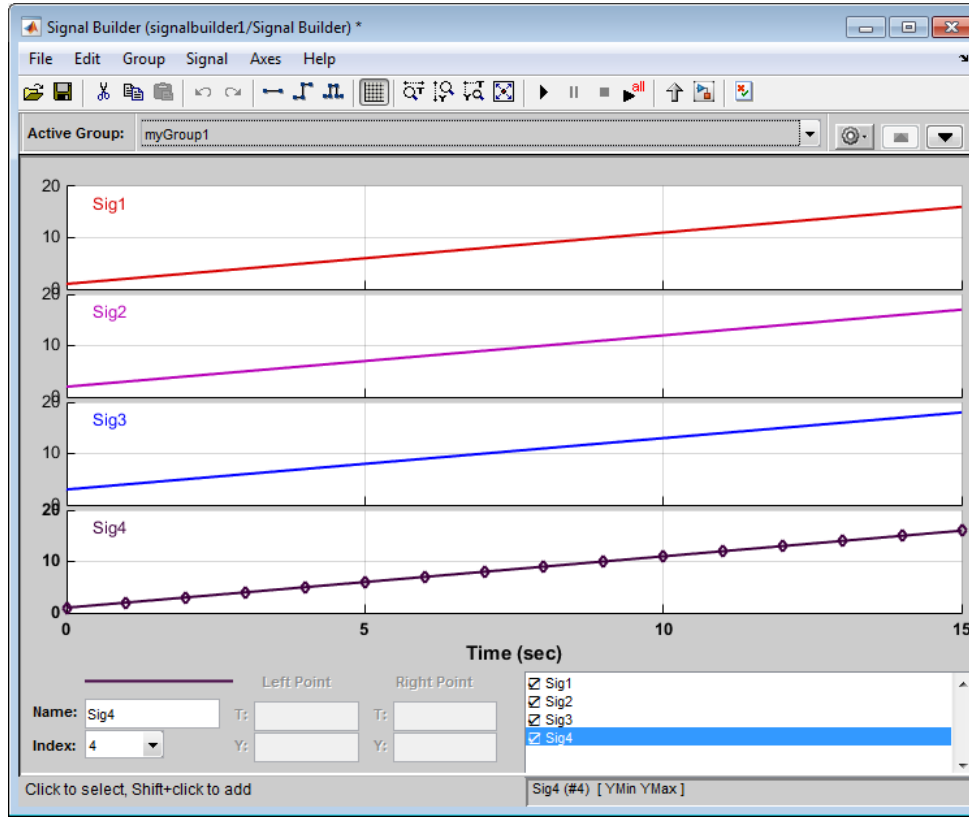
Selected unique signal name:
After:
  Sig4
```

The confirmation also enables the **OK** and **Apply** buttons.

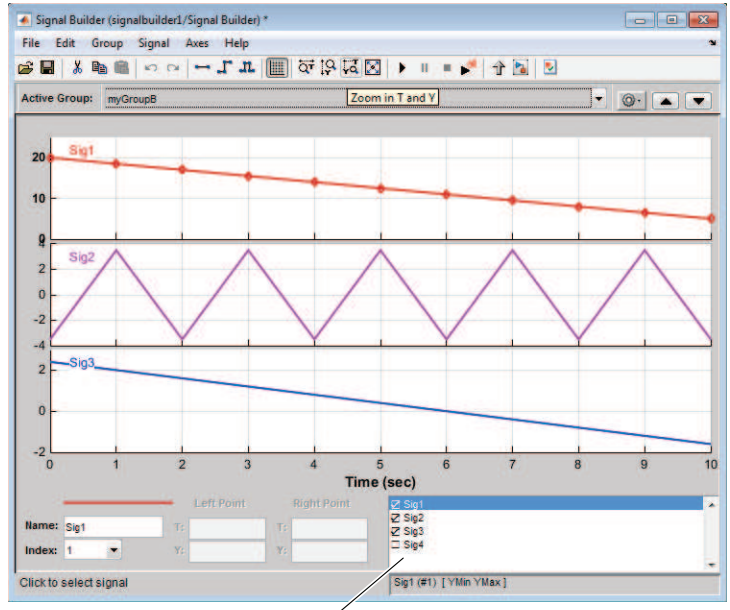
10 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

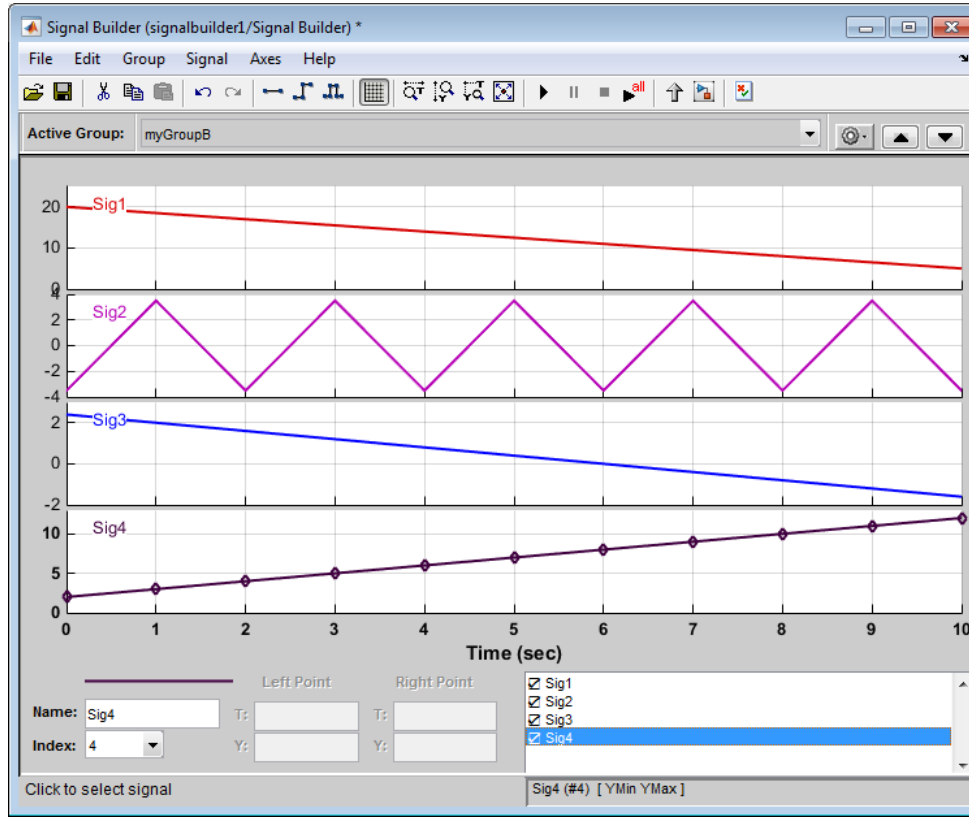
The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.



11 Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.



12 To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.



13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder3`.

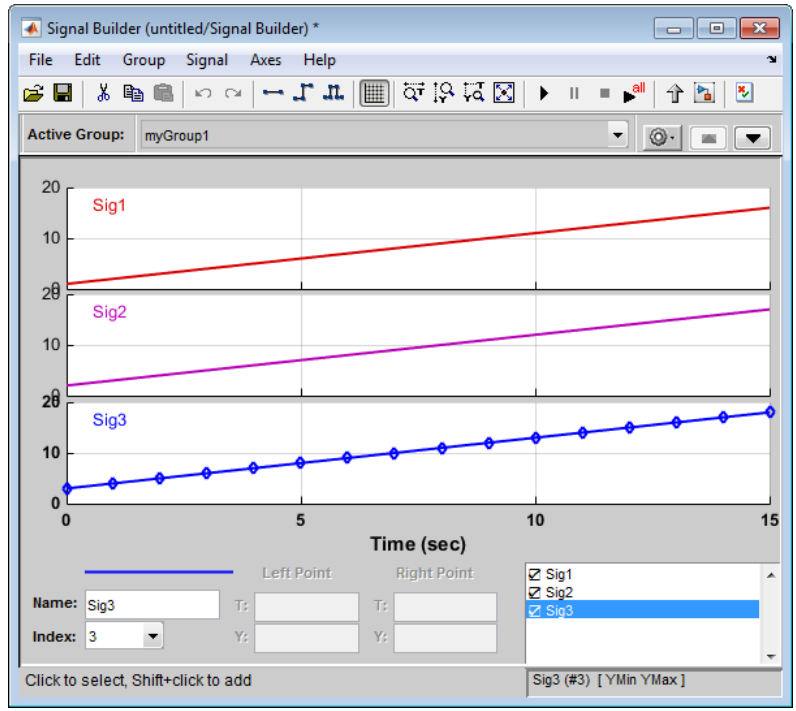
Appending Signal Groups to Existing Groups

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named `MyGroup1`, the software renames the imported group to `MyGroup2` upon appending. If you add another group named `MyGroup1`, the software names that latest version `MyGroup3`.

This topic uses `signalbuilder1` from the procedure in "Replacing All Signal Data with Selected Data" on page 62-83.

1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

   The Signal Builder window appears.
3. Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, myGroup1, myGroupB, and myGroup_Three. Three signals exist in each group.



4. Double-click the block.

   The Import File dialog box appears.
5. In the **File to Import** text field, enter a signal data file name or click **Browse**.

   The file browser appears.
6. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.

8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select myGroupB.

9 From the **Placement for Selected Data** list, select the action to take on the signal group. For example, select `Append groups`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

10 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
1 group(s) (each with 3 signal(s)),
will be appended to the existing block.
Selected group name(s):
Before:
  myGroupB

After:
  myGroupB1

Signal name(s) in selected group(s):
Before:
  Sig1
  Sig2
  Sig3

Signal name(s) in the block:
Before:
  Sig1
  Sig2
  Sig3

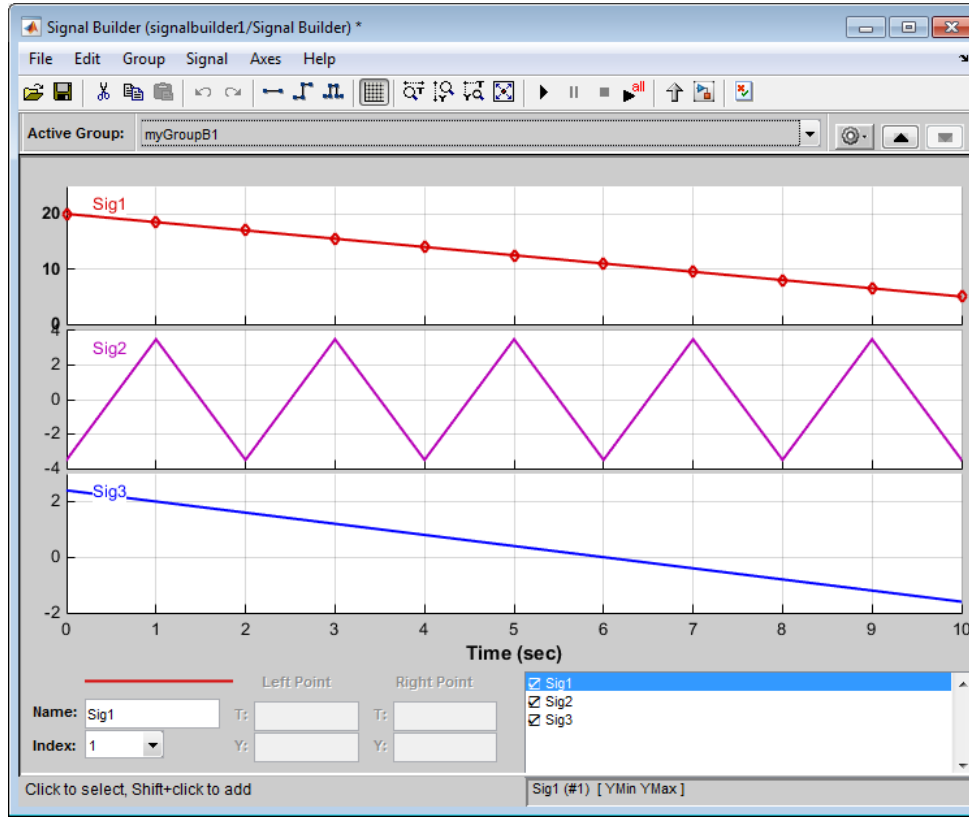
After:
  Sig1
  Sig2
  Sig3
```

The confirmation also enables the **OK** and **Apply** buttons.

11 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB.



12 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals Sig1, Sig2, and Sig3.

2 Append a signal named Sig1 to `myGroup1`.

3 Observe that the software increments Sig1 to Sig4 before appending it to `myGroup1`.

Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

1. Assume your Signal Builder block has a signal group, `myGroup1`, with the signals Sig1, Sig2, and Sig3.
2. Append a signal group named `myGroup2` whose signal names are SigA, SigB, and SigC.
3. Observe that the software:
   - Appends `myGroup2`.
   - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have a signal data from a file whose contents you want to import. See "Importing Signal Groups from Existing Data Sets" on page 62-78 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder *`matlabroot`*`\help\toolbox\simulink\examples` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

Group1	Time	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	Signal1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal2	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal3	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal4	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Group2	Signal1	1.6	2.6	3.6	4.6	5.6	6.6	7.6	8.6	9.6	10.6	11.6	12.6	13.6	14.6	15.6	16.6
	Signal2	1.8	2.8	3.8	4.8	5.8	6.8	7.8	8.8	9.8	10.8	11.8	12.8	13.8	14.8	15.8	16.8
	Signal3	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
	Signal4	2.2	3.2	4.2	5.2	6.2	7.2	8.2	9.2	10.2	11.2	12.2	13.2	14.2	15.2	16.2	17.2

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that uses `xlsread` to read Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
  - *`grpNames`* — Cell array that contains group name strings with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name strings with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1x*N*] or [*N*x1], where *N* is the number of data points in every signal.

1. Identify the format of your custom signal data, for example:

   ```
   SigBldCustomFile.xls
   ```

2. Create a custom MATLAB function that:

   a. Uses a MATLAB I/O function, such as `xlsread`, to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.

   b. Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

3. Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

   ```
   createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
   ```

4. Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 62-77).

Editing Waveforms

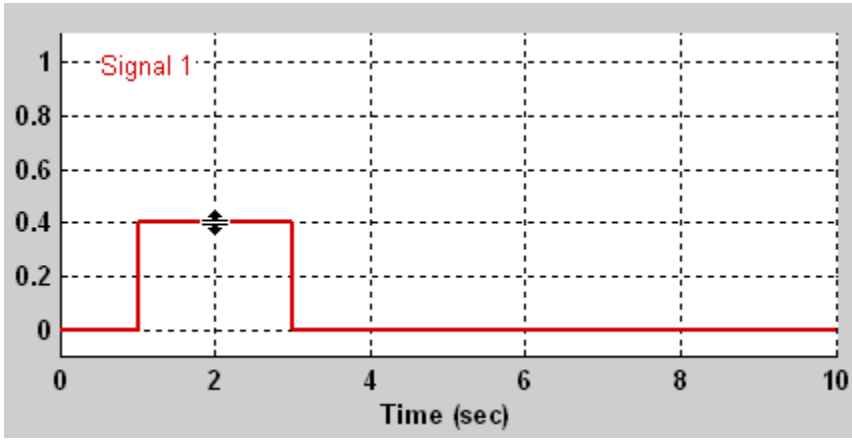
Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

Reshaping a Waveform

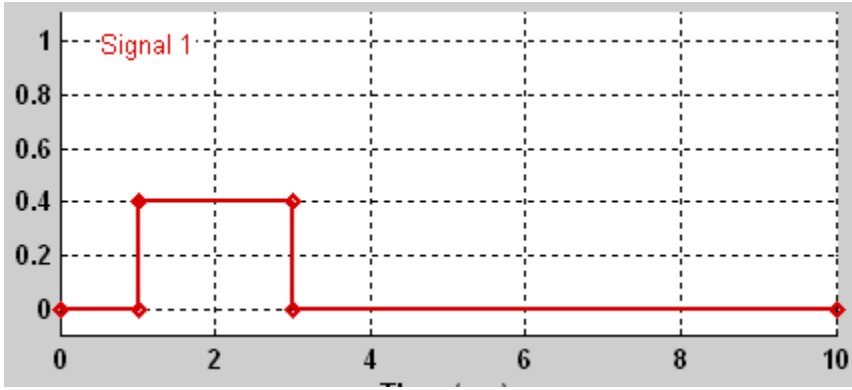
Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.



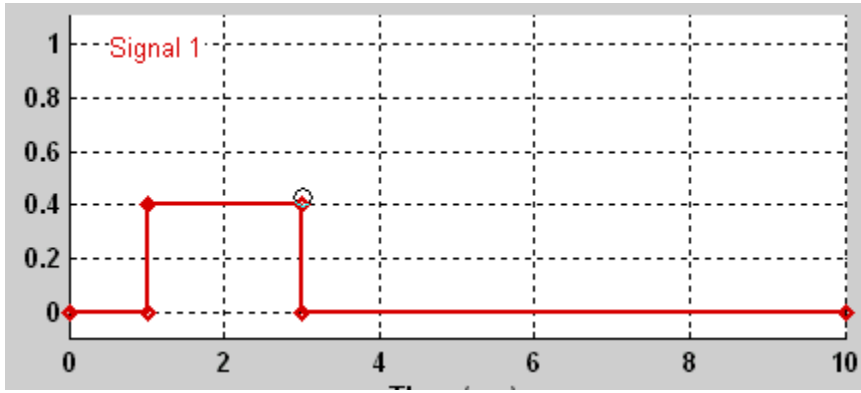
The Signal Builder displays the waveform points to indicate that the waveform is selected.



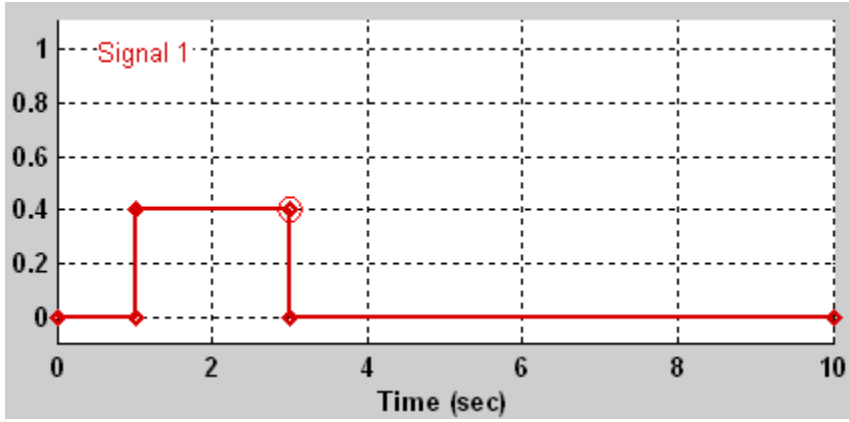
To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

Selecting Points

To select a point of a waveform, first select the waveform. Then position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.



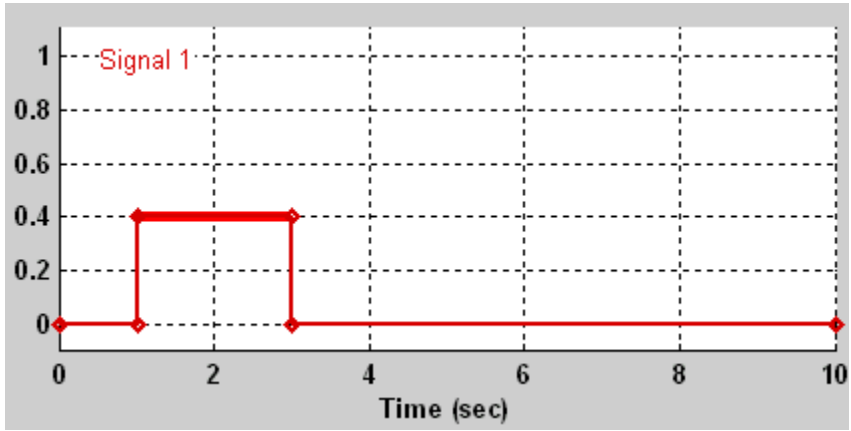
Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.



To deselect the point, press the **Esc** key.

Selecting Segments

To select a line segment, first select the waveform that contains it. Then left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.



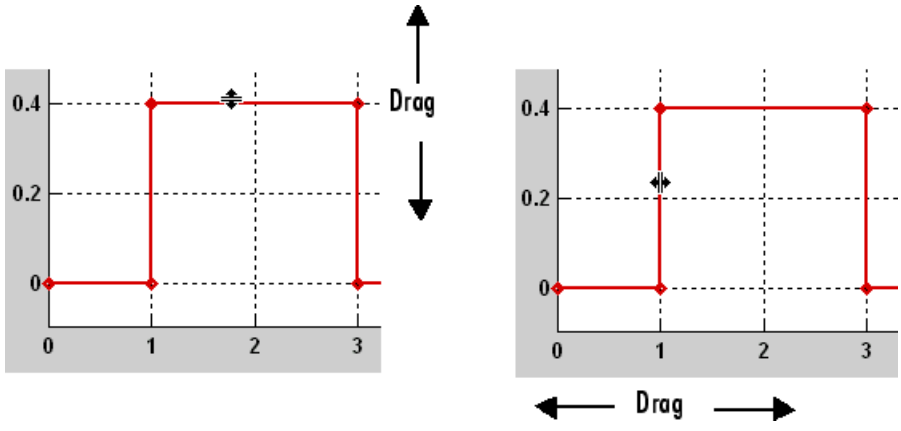
To deselect the segment, press the **Esc** key.

Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see "Snap Grid" on page 62-107) or by `0.1` inches if the snap grid is not enabled.

Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.



Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

Dragging points

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the *y*-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

Snap Grid

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

Inserting and Deleting points

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

Editing Point Coordinates

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

Editing Segment Coordinates

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point**

and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. A menu of line styles pops up. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. A dialog box appears with the line current thickness. Edit the thickness value and click **OK**.

Signal Builder Time Range

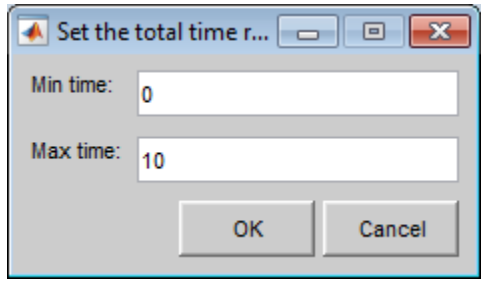
The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change both the beginning and ending times of a block time range (see "Changing a Signal Builder Time Range" on page 62-109).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see "Signal values after final time" on page 62-112 for more information).

Note: When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

Changing a Signal Builder Time Range

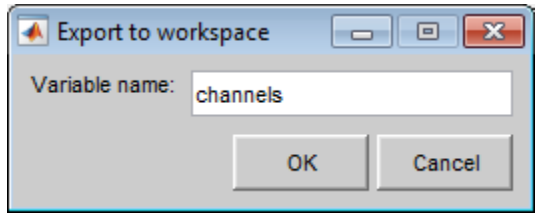
To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu. A dialog box appears.



Edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively. Click **OK**.

Exporting Signal Group Data

To export the data that define a Signal Builder block signal groups to the MATLAB workspace, select **Export to Workspace** from the block **File** menu. A dialog box appears.



The Signal Builder exports the data by default to a workspace variable named `channels`. To export to a differently named variable, enter the variable name in the **Variable name** field. Click **OK**. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure `xData` and `yData` fields contain the coordinate points defining signals in the currently selected signal group. You can access the coordinate values defining signals associated with other signal groups from the structure `allXData` and `allYData` fields.

Printing, Exporting, and Copying Waveforms

Signal Builder allows you to print, export, and copy the waveforms visible in the active signal group.

To print the waveforms to a printer, select **Print** from the block **File** menu.

You can also export the waveforms to other destinations by using the **Export** option from the block **File** menu. From this submenu, select one of the following destinations:

- **To File** — Converts the current view to a graphics file.

  Select the format of the graphics file from the **Save as type** drop-down list on the resulting **Export** dialog box.
- **To Figure** — Converts the current view to a MATLAB figure window.

To copy the waveforms to the system clipboard for pasting into other applications, select **Copy Figure To Clipboard** from the block **Edit** menu.

Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see "Running All Signal Groups" on page 62-111).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, etc., all from the Signal Builder window.

Running All Signal Groups

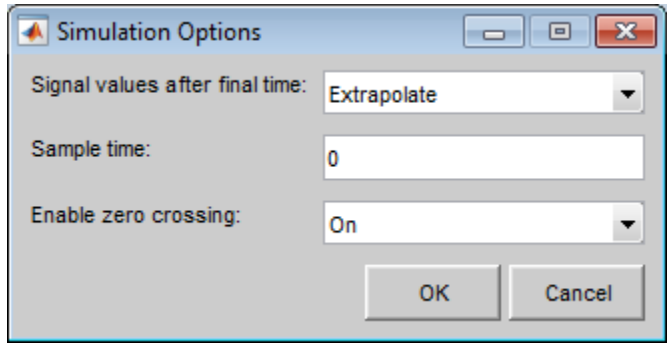
To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the **Run all** button

from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Verification and Validation on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

Note To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

Simulation Options Dialog Box

The **Simulation Options** dialog box allows you to specify simulation options pertaining to the Signal Builder. To display the dialog box, select **Simulation Options** from the **File** menu of the Signal Builder window. The dialog box appears.



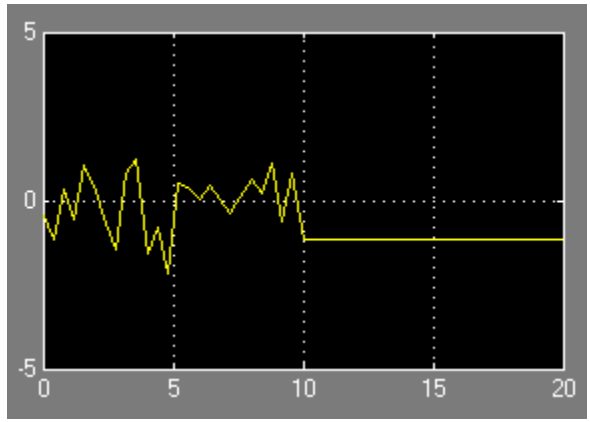
The dialog box allows you to specify the following options.

Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block. The options are

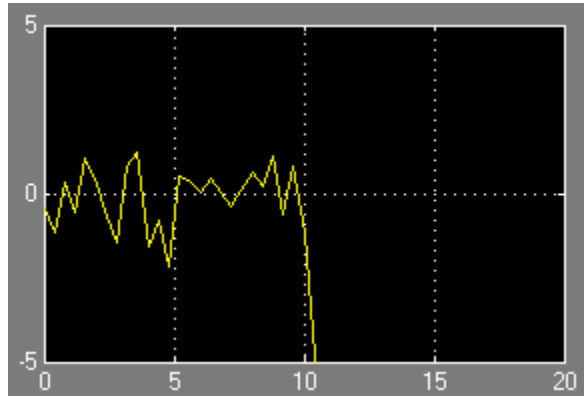
- `Hold final value`

  Selecting this option causes the Signal Builder block to output the last defined value of each signal in the currently active group for the remainder of the simulation.



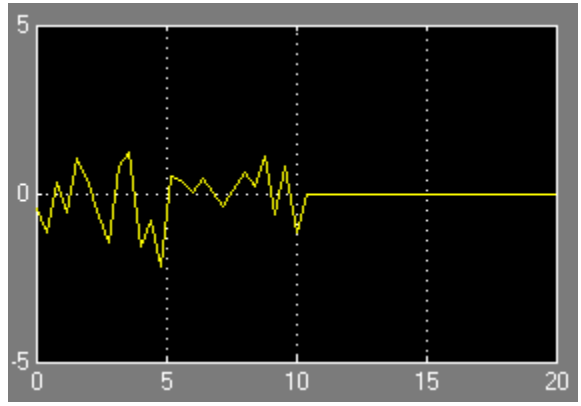
- `Extrapolate`

  Selecting this option causes the Signal Builder block to output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation.



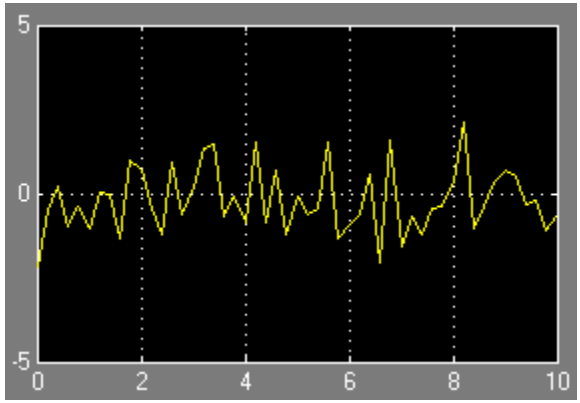
- `Set to zero`

  Selecting this option causes the Signal Builder block to output zero for the remainder of the simulation.

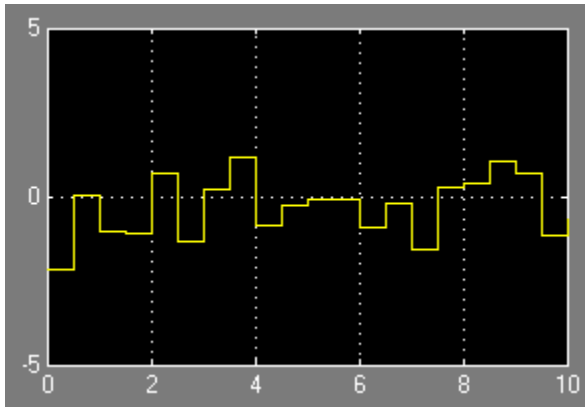


Sample time

Determines whether the Signal Builder block outputs a continuous (the default) or a discrete signal. If you want the block to output a continuous signal, enter 0 in this field. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.



If you want the block to output a discrete signal, enter the sample time of the signal in this field. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a `0.5` second sample time.



Enable zero crossing

Specifies whether the Signal Builder block detects zero-crossing events (enabled by default). This block sets the zero-crossing detection on the `From Workspace` block that you use to create the Signal Builder signal groups. For more information, see "Zero-Crossing Detection" on page 3-24.

Composite Signals

In this section...
"What is a Composite Signal?" on page 63-3 "Techniques for Combining Signals" on page 63-3

What is a Composite Signal?

A *composite signal* is a signal that is composed of other signals. The constituent signals originate separately and join to form the composite signal. You can then extract individual signals from the composite signal downstream and use the signal as if it had never been part of a composite signal.

Composite signals can reduce visual complexity in models by grouping signals that run in parallel over some or all of their courses. Composite signals offer other benefits, as described in the documentation for each technique for combining signals.

Techniques for Combining Signals

Simulink provides several techniques for combining signals into a composite signal, depending on your modeling requirements.

Composite Signal Technique	When to Use
Virtual bus	Combine signals of any type and dimension, without affecting the memory layout. Use for graphical convenience. See "Choose Between Virtual and Nonvirtual Buses" on page 63-15.
Nonvirtual bus	Combine signals of different types and dimensions such that they are contiguous in memory. Produces a structure in the generated code. See "Choose Between Virtual and Nonvirtual Buses" on page 63-15.

Composite Signal Technique	When to Use
Mux block	Graphically combine signals of same type. See "Buses and Muxes" on page 63-4.
`Vector Concatenate` and `Matrix Concatenate` block	Create a vector or matrix, for example to be used in mathematical operations. The resulting vector is stored in contiguous memory.
Array of buses	Combine multiple buses with identical properties. Array of buses is equivalent to an array of structures in MATLAB. See "Combine Buses into an Array of Buses" on page 63-91.

Buses and Muxes

If all signals in a bus are the same type, you may be able to use a contiguous vector or a virtual vector (mux) instead of a bus. For more information, see "Mux Signals" on page 62-11.

In the context of a model, do not use bus and mux mixtures. A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus. For more information, see "Prevent Bus and Mux Mixtures" on page 63-123.

Bus Code

The various techniques for defining buses are essentially equivalent for simulation, but the techniques used can make a significant difference in the efficiency, size, and readability of generated code. If you intend to generate code for a model that uses buses, for information about the best techniques to use, in the Simulink Coder documentation, see "Generate Efficient Code for Bus Signals".

Function-Call Signals

To combine function-call signals to call a single system, use a Mux block.

If you use a Bus Creator block to group function-call signals into one bus, then use a Bus Selector block to separate out specific function-call signals.

Buses

In this section...
"What is a Bus?" on page 63-6
"Types of Simulink Buses" on page 63-7
"Bus Objects" on page 63-7
"View Information about Buses" on page 63-7

Tip Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see "Techniques for Combining Signals" on page 63-3.

What is a Bus?

A Simulink composite signal is called a *bus signal*, or just a *bus*. A Simulink bus is analogous to a bundle of wires held together by tie wraps. Simulink implements a bus as a name-based hierarchical structure. A Simulink bus should not be confused with a hardware bus, like the bus in the backplane of many computers. It is more like a programmatic structure defined in a language like C.

The signals that constitute a bus are called *elements*. The constituent signals retain their separate identities within the bus and can be of any type or types, including other buses nested to any level. The elements of a bus can be any of the following:

- Mixed data type signals (e.g. double, integer, fixed point)
- Mixture of scalar and vector elements
- Buses as elements
- N-D signals
- Mixture of Real and Complex signals

Some requirements and limitations apply when you connect buses to blocks or to nonvirtual subsystems. See "Bus-Capable Blocks" on page 63-25, "Use Buses for Inports and Outports" on page 63-71, and "Composite Signal Limitations" on page 63-146 for more information.

Types of Simulink Buses

A bus can be either *virtual* or *nonvirtual*. Both virtual and nonvirtual buses provide the same visual simplification, but their implementations are different.

- Virtual buses exist only graphically. They have no functional effects and do not appear in generated code; only the constituent signals appear. See "Virtual Signals" on page 62-11 for details. Simulink implements virtual buses with pointers, so virtual buses add no data copying overhead and do not affect performance.
- Nonvirtual buses may have functional effects. They appear as structures in generated code, which can simplify the code and clarify its correspondence with the model. Simulink implements nonvirtual buses by copying data from the source signals to the bus, which can affect performance.

The two types of buses are interchangeable for many purposes, but some situations require a nonvirtual bus. See "Virtual and Nonvirtual Buses" on page 63-14 for more information.

Bus Objects

A bus can have an associated *bus object*, which can both provide and validate bus properties. A bus object is an instance of class `Simulink.Bus` that is defined in the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size. Bus objects are optional for virtual buses and required for nonvirtual buses. See "Bus Objects" on page 63-27 for more information. You can create bus objects programmatically or by using the Simulink Bus Editor, which facilitates bus object creation and management. See "Manage Bus Objects with the Bus Editor" on page 63-33 for more information.

View Information about Buses

To view information about buses, use one of the following approaches:

- To see full paths for Bus Selector and Bus Assignment blocks, hover over an input signal or the block.
- to interactively display bus signals in a bus hierarchy, use the Signal Hierarchy Viewer
- From the MATLAB command line, display the type and hierarchy of a bus signal in a compiled model. For details, see "CompiledBusType and SignalHierarchy Parameters" on page 63-10.

Display Full Paths to Bus Selector and Bus Assignment Block Signals

You can display full paths to bus signals for Bus Selector and Bus Assignment blocks in the Simulink Editor, without opening the Block Parameters dialog boxes for the blocks. Interactively viewing the full signal path can simplify the process of editing signals with duplicate leaf names, by eliminating the need to match the block ports with the associated signals. Also, interactively viewing the full path for the signal provides a quick way to get context for understanding the model.

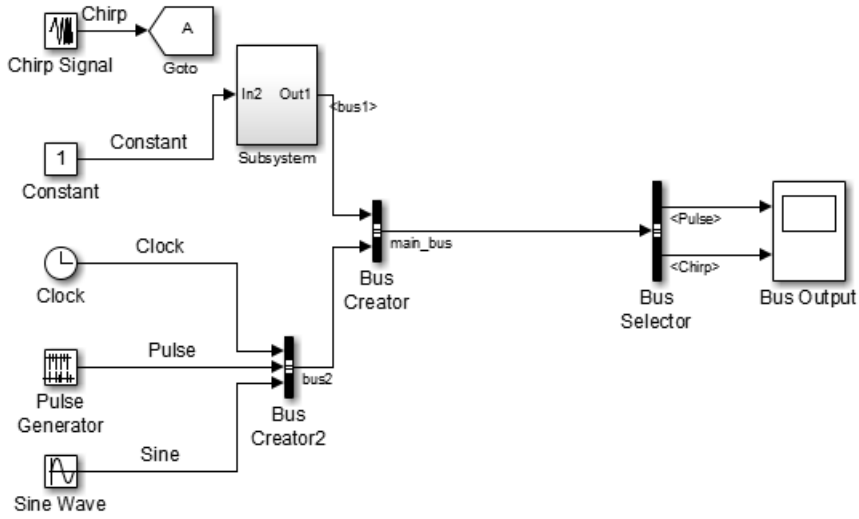
- To see the full path of an Bus Selector block output signal, hovering over the output signal label.
- To see the full path of up to the first ten output signals of a Bus Selector block, hover over the block.
- To see the full path of up to the first ten signals in a Bus Assignment block, hover over the block.

Signal Hierarchy Viewer

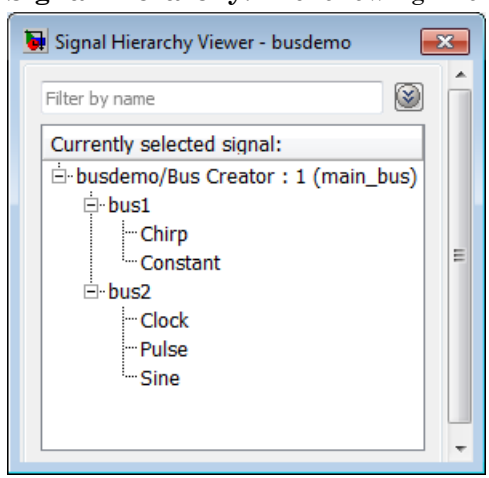
Use the Signal Hierarchy Viewer to interactively display information about a signal. For a bus signal, the Signal Hierarchy Viewer displays the bus hierarchy.

1. Check that the **Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** parameter is set to `error`.
2. Right-click a signal line.
3. Select the **Signal Hierarchy** option. The Signal Hierarchy Viewer dialog box appears.

For example, open the `busdemo` model.



Right-click the `main_bus` signal (output signal for the Bus Creator block), and select **Signal Hierarchy**. The following information appears:



Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

You can also open the Signal Hierarchy Viewer in the Simulink Editor.

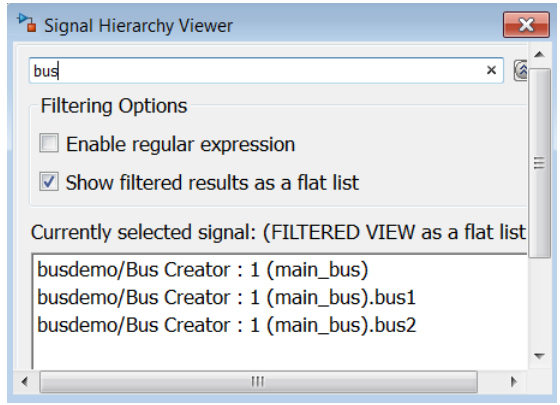
1 Select **Diagram > Signals & Ports > Signal Hierarchy**.

2 Select a signal

Note: To produce accurate results at edit time, the Signal Hierarchy Viewer requires that the model compiles successfully.

To filter the displayed signals, click the **Options** button on the right-hand side of the **Filter by name** edit box ( ).

- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, entering `r$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `r` (and their immediate parents). For details, see "Regular Expressions".
- To use a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box, select **Show filtered results as a flat list**. The flat list format uses dot notation to reflect the hierarchy of bus signals. The following is an example of a flat list format for a filtered set of nested bus signals.



CompiledBusType and SignalHierarchy Parameters

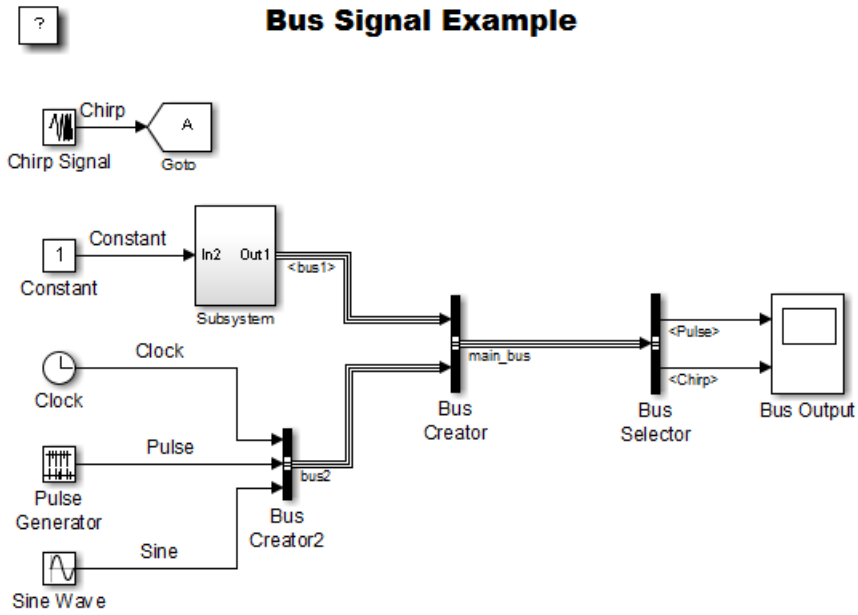
To get information about the type and hierarchy of a bus signal in a compiled model, use these parameters with the `get_param` command:

- `CompiledBusType` — For a compiled model, returns information about whether the signal connected to a port is a bus, and if so, whether the signal is a virtual or nonvirtual bus.
- `SignalHierarchy` — If the signal is a bus, returns the name and hierarchy of the signals in the bus.

Before you use these commands:

1. Set the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** diagnostic to `error`.
2. Update the diagram or simulate the model.

For example, if you open and simulate the `busdemo` model, the model looks as shown below:



The following code illustrates how you can use the `SignalHierarchy` and `CompiledBusType` parameters:

```
mdl = 'busdemo';
open_system(mdl)
```

```
% Obtain the handle a port
ph = get_param([mdl '/Bus Creator'], 'PortHandles');
% SignalHierarchy is available at edit time
sh = get_param(ph.Outport, 'SignalHierarchy')
% Compile the model
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
% Terminate the model
busdemo([],[],[],'term');
```

Virtual and Nonvirtual Buses

In this section...
“About Virtual and Nonvirtual Buses” on page 63-14
“Choose Between Virtual and Nonvirtual Buses” on page 63-15
“Nonvirtual Bus Sample Times” on page 63-16
“Automatic Bus Conversion” on page 63-16
“Explicit Bus Conversion” on page 63-17

About Virtual and Nonvirtual Buses

A bus signal can be *virtual*, meaning that it is just a graphical convenience that has no functional effect, or *nonvirtual*, meaning that the signal occupies its own storage.

Bus Signal Lines

When you simulate a model that contains buses, Simulink uses different line styles for virtual and nonvirtual bus signals.

Virtual Bus	Nonvirtual Bus	

Bus Storage

During simulation:

- A block connected to a *virtual* bus reads inputs and writes outputs by accessing the memory allocated to the component signals. These signals are typically noncontiguous, and no intermediate memory exists.
- A block connected to a *nonvirtual* bus reads inputs and writes outputs by accessing copies of the component signals. The copies are maintained in a contiguous area of memory allocated to the bus.

Compared with nonvirtual buses, virtual buses reduce memory requirements because they do not require a separate contiguous storage block, and execute faster because they do not require copying data to and from that block.

A nonvirtual bus is represented by a structure in generated code, which can be helpful when tracing the correspondence between the model and the code.

Choose Between Virtual and Nonvirtual Buses

Whether to use a virtual or nonvirtual bus depends on your modeling goal. Frequently, a model contains both virtual and nonvirtual buses.

Modeling Goal	Type of Bus
Use bus signals within a functional unit, such as within a referenced model	Virtual
Use signals with different sample rates in a bus	Virtual (required)
Have bus data packaged as data structures in the generated code	Nonvirtual
Have bus signals cross model reference boundaries	Virtual or nonvirtual For nonvirtual buses, consider stripping out unneeded data from bus objects crossing model reference boundaries. In large models, bus objects can become quite large and have several levels of hierarchy. Often referenced models need some, but not all, of the data contained in large buses. Passing unneeded data across model reference boundaries impacts performance negatively. The interface definition for a model should specify exactly what data the model uses. Use a bus object to define the data type for the root-level Inport and Outport blocks.
Have bus data cross MATLAB Function block or Stateflow chart boundaries	Nonvirtual
Interface with external code either through an S-function or the Legacy Code Tool	Nonvirtual

Not all blocks can accept buses. See "Bus-Capable Blocks" on page 63-25 for more about which blocks can handle which types of buses. Virtual buses are the default except where nonvirtual buses are explicitly required. See "Use Buses for Inports and Outports" on page 63-71 for more information.

In general, virtual buses do not affect the generated code. You can optionally use nonvirtual buses to group signals into structures in the generated code. For additional guidelines for generated code for nonvirtual buses, see "Group Signals into Structures in the Generated Code Using Buses".

Nonvirtual Bus Sample Times

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error.

All buses and signals input to a Bus Creator block that outputs a nonvirtual bus must therefore have the same sample time. You can use a `Rate Transition` block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

Automatic Bus Conversion

When updating a diagram prior to simulation or code generation, Simulink automatically converts a virtual bus to a nonvirtual bus (or vice versa) in cases such as when the virtual bus is an input to, or output from:

- An S-Function block
- A Stateflow chart

When you pass a bus signal into a referenced model, Simulink makes the bus a virtual or nonvirtual bus to match the type of bus specified for the Inport block it feeds. Bus signal outputs are virtual or nonvirtual, based on the specification for the Outport block. For bus signals driving a root-level Outprt block, Simulink performs a similar conversion. For more information, see "Bus Data Crossing Model Reference Boundaries" on page 63-119.

The conversion consists of inserting hidden `Signal Conversion` blocks into the model where needed. Conversion to a nonvirtual bus fails if no bus object is specified at the port to which the virtual bus connects.

Explicit Bus Conversion

You can eliminate the need for the automatic conversion by using one of these approaches:

- Specify a nonvirtual bus in the block where the bus originates. For example, if you use a Bus Creator block to create a bus, then to specify a nonvirtual bus, set the `Bus Creator` block **Data type** parameter to use a `Simulink.Bus` object.
- Manually insert a Signal Conversion block. Using a Signal Conversion block can reduce memory usage, support modeling constructs such as Model blocks that require that input buses be nonvirtual, and reduce generated code. For details, see the `Signal Conversion` documentation.

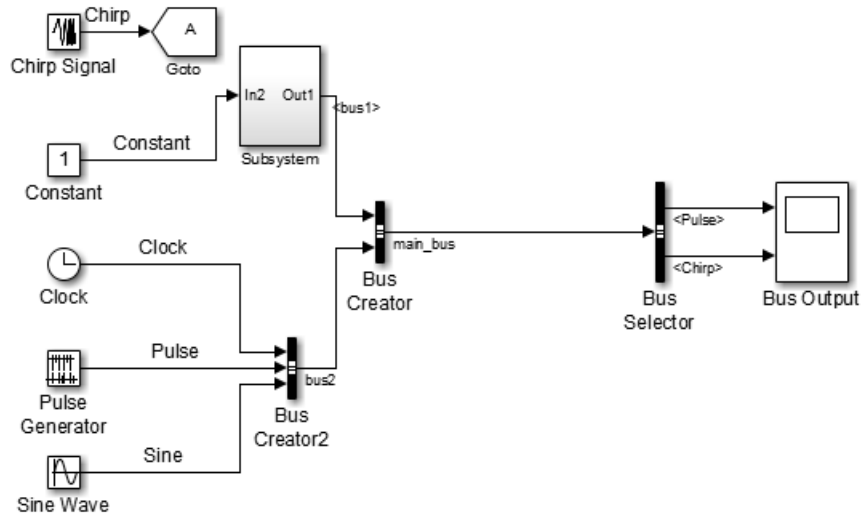
Create Bus Signals

In this section...
“Create a Bus” on page 63-19
“Create a Nonvirtual Bus” on page 63-20

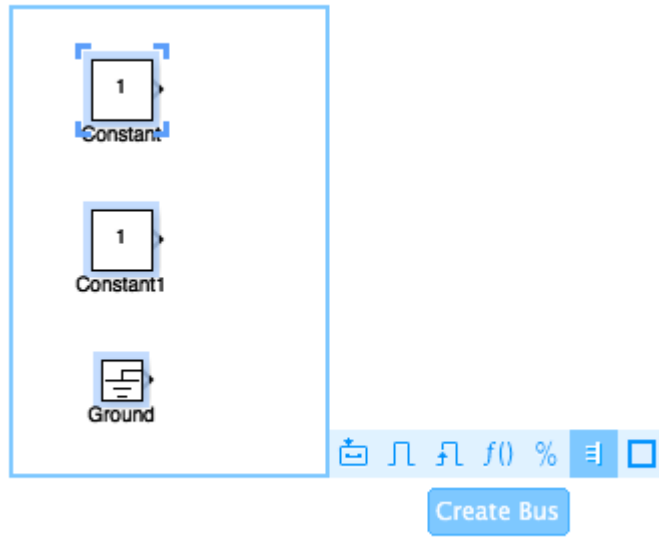
You can combine signals into a bus signal and then access the bus as a whole or select specific signals from the bus.

The `busdemo` top-level model uses a Bus Creator block to combine the `Clock`, `Pulse`, and `Sine` signals into the `bus2` bus signal. The model combines the `bus2` signal and the subsystem signal to form the `main_bus` signal. The model uses a Bus Selector to select two signals (bus elements) from the bus and output the signals to a Scope block.



Create a Bus

1. In the Simulink Editor, drag to select multiple blocks or signals that you want to create a bus for.
2. In the action bar that appears, click **Create Bus**.



Using the **Create Bus** button to create a bus automatically performs these actions:

- Creates a Bus Creator block with the right number of inputs
- Resizes the Bus Creator block to an appropriate size for the number of input signals
- Orients the Bus Creator block to the direction of the input signals
- Connects the signals to the Bus Creator block

As an alternative, you can add a Bus Creator block to a model and manually connect signals to that block to create a bus.

Create a Nonvirtual Bus

Bus signals do not specify whether they are virtual or nonvirtual; they inherit that specification from the block in which they originate. Every block that creates or requires a nonvirtual bus must have an associated bus object. Those blocks are:

- `Bus Creator`
- `Inport`

- `Outport`
- `Constant`
- `Data Store Memory`

To specify that a bus is nonvirtual:

1. Associate the block with a bus object, as described in "Associate Bus Objects with Simulink Blocks" on page 63-28.
2. For the block that creates the bus, open the Block Parameters dialog box.
3. Set the data type to `Bus: <object name>` and replace `<object name>` with the bus object name.
   - For Inport, Outport, and Data Store Memory blocks, use the **Data type** parameter to set the data type.
   - For Bus Creator and Constant blocks, use the **Output data type** parameter to set the data type.
4. For any Bus Creator, Inport, or Outport blocks that have an associated bus object, enable the output as a nonvirtual bus.
   - For Bus Creator and Inport blocks, use the **Output as nonvirtual bus** parameter.
   - For Outport blocks, use the **Output as nonvirtual bus in parent model** parameter.
5. Click **OK** or **Apply**.

The **Signal Attributes** parameter is applicable only to root Inport and Outport blocks. It does not appear in the parameters of a subsystem Inport or Outport block. In a root Outport block, setting **Signal Attributes > Output as nonvirtual bus in parent model** specifies that the bus emerging in the parent model is nonvirtual. The input bus of the root Outport can be virtual or nonvirtual.

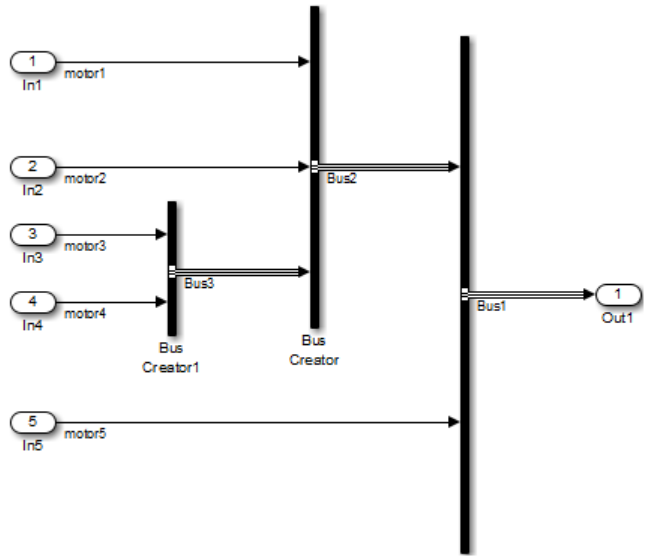
More About

- "Buses" on page 63-6
- "Virtual and Nonvirtual Buses" on page 63-14

Nest Buses

You can nest buses to any depth. To create a nested bus, use a `Bus Creator` block. If one of the inputs to the Bus Creator block is a bus, then the output is a nested bus. To select a signal within a nested bus, use a `Bus Selector` block.

For example, in the next model, the `Bus3` bus signal combines two signals, `motor3` and `motor4`. The `Bus2` signal combines the `Bus3` bus signal and the `motor1` and `motor2` signals. The `Bus1` signal combines the `Bus2` bus signal and the `motor5` signal.



All of the signals retain their separate identities, just as if no bus creation and selection occurred. You can use Bus Selector blocks to select individual signals from a nested bus.

The Simulink software automatically handles most of the complexities involved. For example, you can specify to have Simulink repair broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. To enable these automatic repairs, in the**Configuration Parameters** > **Diagnostics** > **Connectivity** pane, set the **Repair bus selections** diagnostic to `Warn and repair`. The repairs occur when you update a model. To save the repairs, save the model.

Circular Bus Definitions

The ability to nest a bus as an element of another bus creates the possibility of a loop of Bus Creator blocks, Bus Selector blocks, and bus-capable blocks that inadvertently includes a bus as an element of itself. The resulting circular definition cannot be resolved and therefore causes an error.

The error message that appears specifies the location at which the Simulink software determined that the circular structure exists. The error is not really at any one location: the structure as a whole is in error. Nonetheless, the location cited in the error message can be useful for beginning to trace the definition cycle; its structure may not be obvious on visual inspection.

1. Begin by selecting a signal line associated with the location cited in the error message.
2. Choose **Highlight to Signal to Source** or **Highlight Signal to Destination** from the signal's context menu. (See “Display Signal Sources and Destinations” on page 62-38 for more information.)
3. Continue choosing signals and highlighting their sources and destinations until the cycle becomes clear.
4. Restructure the model as needed to eliminate the circular bus definition.

Because the problem is a circular definition rather than a circular computation, the cycle cannot be broken by inserting additional blocks, in the way that an algebraic loop can be broken by inserting a Unit Delay block. No alternative exists but to restructure the model to eliminate the circular bus definition.

More About

- “Buses” on page 63-6

Bus-Capable Blocks

All virtual blocks are bus-capable. The following blocks are also bus-capable. Some blocks only support nonvirtual buses.

- `Bus Assignment`
- `Bus Creator`
- `Bus Selector`
- `Constant` (nonvirtual buses)
- `Data Store Memory` (nonvirtual buses)
- `Data Store Read` (nonvirtual buses)
- `Data Store Write` (nonvirtual buses)
- `From Workspace` (nonvirtual buses)
- `Memory`
- `Merge`
- `Multiport Switch`
- `Rate Transition`
- `Signal Conversion`
- `Signal Specification`
- `Switch`
- `To Workspace`
- `Unit Delay`
- `Zero-Order Hold`

All signals in a nonvirtual bus input to a bus-capable block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a `Rate Transition` block to change the sample time of an individual signal, or of all signals in a bus.

Some bus-capable blocks impose other constraints on bus propagation through them. See the documentation for specific blocks for more information.

Subsystems, model referencing and S-functions support the use of buses. See the documentation for those features for any special considerations relating to the use of buses.

Bus Objects

In this section...
"About Bus Objects" on page 63-27
"Bus Object Capabilities" on page 63-28
"Associate Bus Objects with Simulink Blocks" on page 63-28

About Bus Objects

The properties that you specify for a bus signal by using Bus Creator block parameters are inherited by all downstream blocks that use the bus. Using Bus Creator block parameters is adequate for defining virtual buses and performing limited error checking. However, to define a nonvirtual bus, or to perform complete error checking on any bus, use a *bus object* to specify additional information.

Creating a bus object establishes a composite data type whose name is the name of the bus object and whose properties are given by the object. A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. A bus object is an instance of class `Simulink.Bus` that is defined in the base workspace. A bus object serves as the root of an ordered hierarchy of *bus elements*, which are instances of class `Simulink.BusElement`. Each element completely specifies the properties of one signal in a bus: its name, data type, dimensionality, etc. The order of the elements contained in the bus object defines the order of the signals in the bus.

Referenced models, Stateflow charts, and MATLAB Function blocks that input and output buses require those buses to be defined with bus objects. Inport and Outport blocks can use bus objects to specify the structure of the bus passing through them. Root inport blocks use bus objects to specify the structure of the bus. Root outport blocks use bus objects to check the structure of the incoming bus and to specify the structure of the bus in the parent model, if any.

Bus Object Capabilities

You can associate a bus object with several blocks. For details, see “Associate Bus Objects with Simulink Blocks” on page 63-28.

When a bus object governs a signal output by a block, the signal is a bus that has exactly the properties specified by the object. When a bus object governs a signal input by a block, the signal must be a bus that has exactly the properties specified by the object; any variance causes an error.

A bus object can also specify properties that were not defined by constituent signals, but were left to be inherited. A property specification in a bus object can either validate or provide the corresponding property in the bus. If the bus specifies a different property, an error occurs. If the bus does not specify the property, but leaves it to be inherited, the bus inherits the property from the bus object. Note again that such inheritance never includes signal values.

You can use the Simulink Bus Editor to create and manage bus objects, as described in “Manage Bus Objects with the Bus Editor” on page 63-33, or you can use the Simulink API, as described in “Bus Object API” on page 63-31. After you create a bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides.

Associate Bus Objects with Simulink Blocks

You can associate a bus object with the following blocks:

- `Bus Creator`
- `Data Store Memory`
- `Data Store Read`
- `Data Store Write`
- `From File`
- `From Workspace`
- `Inport`
- `Outport`
- `Permute Dimensions`
- `Probe`

- `Reshape`
- `Signal Conversion`
- `Signal Specification`

In the Block Parameters dialog box for the block that you want to associate with a bus, set **Data type** to `Bus: <object name>` and replace `<object name>` with the bus object name.

Note: Do not set the minimum and maximum values for bus data on blocks with bus object data type. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

Bus Object API

The Simulink software provides all Bus Editor capabilities programmatically. Many of these capabilities, like importing and exporting MATLAB code files and MAT-files, are not specific to bus objects, and are described elsewhere in the MATLAB and Simulink documentation.

The classes that implement bus objects are:

`Simulink.Bus`

Specify the properties of a signal bus

`Simulink.BusElement`

Describe an element of a signal bus

The functions that create and save bus objects are:

`Simulink.Bus.createObject`

Create bus objects for blocks, optionally saving them in a MATLAB file in a specified format

`Simulink.Bus.cellToObject`

Convert a cell array containing bus information to bus objects in the base workspace

`Simulink.Bus.objectToCell`

Convert bus objects in the base workspace to a cell array containing bus information

`Simulink.Bus.save`

Export specified bus objects or all bus objects from the base workspace to a MATLAB file in a specified format

`Simulink.Bus.createMATLABStruct`

Create MATLAB structure with same hierarchy, names, and attributes as the bus signal

In addition, when you use `Simulink.SubSystem.convertToModelReference` to convert an atomic subsystem to a referenced model, you can save any bus objects created during the conversion to a MATLAB file.

"Change Bus Entities" on page 63-46
"Export Bus Objects" on page 63-50
"Import Bus Objects" on page 63-51
"Close the Bus Editor" on page 63-52

Introduction

The Simulink Bus Editor is a tool similar to the Model Explorer, but is customized for use with bus objects. You can use the Simulink Bus Editor to:

- Create new bus objects and elements
- Navigate, change, and nest bus objects
- Import existing bus objects from a MATLAB code file or MAT-file
- Export bus objects to a MATLAB code file or MAT-file

For a description of bus objects and their use, see "Bus Objects" on page 63-27.

Base Workspace Bus Objects

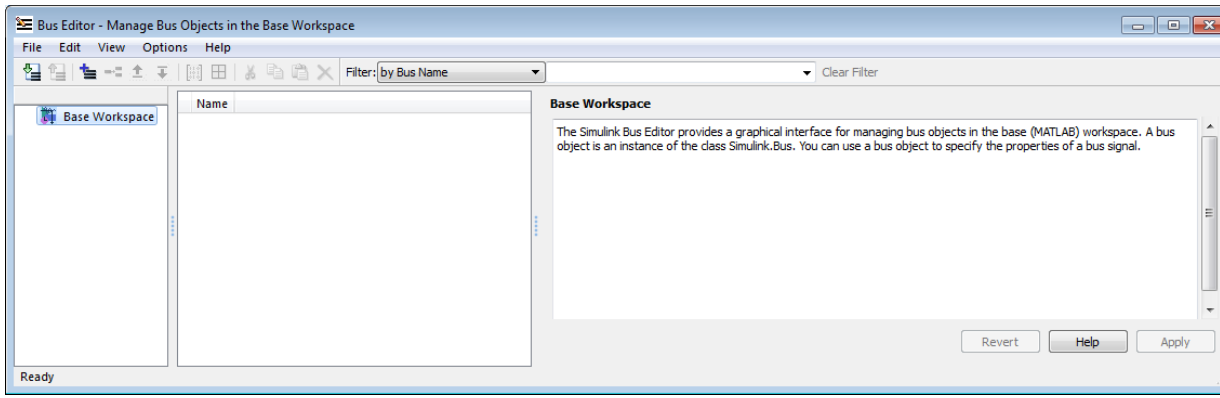
All bus objects exist in the MATLAB base workspace. Bus Editor actions take effect in the base workspace immediately, and can be used by Simulink models as soon as each action is complete. The Bus Editor does not have a workspace of its own: it acts only on the base workspace. Bus Editor actions do not directly affect bus object definitions in saved MATLAB code files or MAT-files. To save changed bus object definitions, export them from the base workspace into MATLAB code files or MAT-files, as described in "Export Bus Objects" on page 63-50.

Open the Bus Editor

You can open the Bus Editor in any of these ways:

- In the Simulink Editor, select **Edit > Bus Editor**.
- In a bus object's dialog box in the Model Explorer, click the **Launch Bus Editor** button.
- Enter `buseditor` at the command line of the MATLAB software.

If no bus objects exist, the Bus Editor looks like the one shown here:



Bus Editor Commands

The Bus Editor provides menu choices that you can use to execute all Bus Editor commands. The editor also provides toolbar icons and keyboard shortcuts for all commonly used commands, including the standard MATLAB shortcuts for Cut, Copy, Paste, and Delete. The Toolbar Tip for each icon describes the command, and the menu entry for each command shows any shortcut. The icons for commands that are specific to the Bus Editor are:

Command	Icon	Description
Import		Import the contents of a MATLAB code file or MAT-file into the base workspace.
Export		Export all bus objects and elements to a MATLAB code file or MAT-file.

Command	Icon	Description
Create		Create a new bus object in the base workspace.
Insert		Add a bus element below the currently selected bus entity.
Move Up		Move the selected element up in the list of a bus object's elements.
Move Down		Move the selected element down in the list of bus object elements.
Create/Edit a Simulink.Parameter object		Create or edit a `Simulink.Parameter` object for the selected bus object.
Create a MATLAB structure		Create a MATLAB structure for the selected bus object.

You can use toolbar icons and keyboard shortcuts instead of menu commands whenever you prefer.

Display Bus Objects

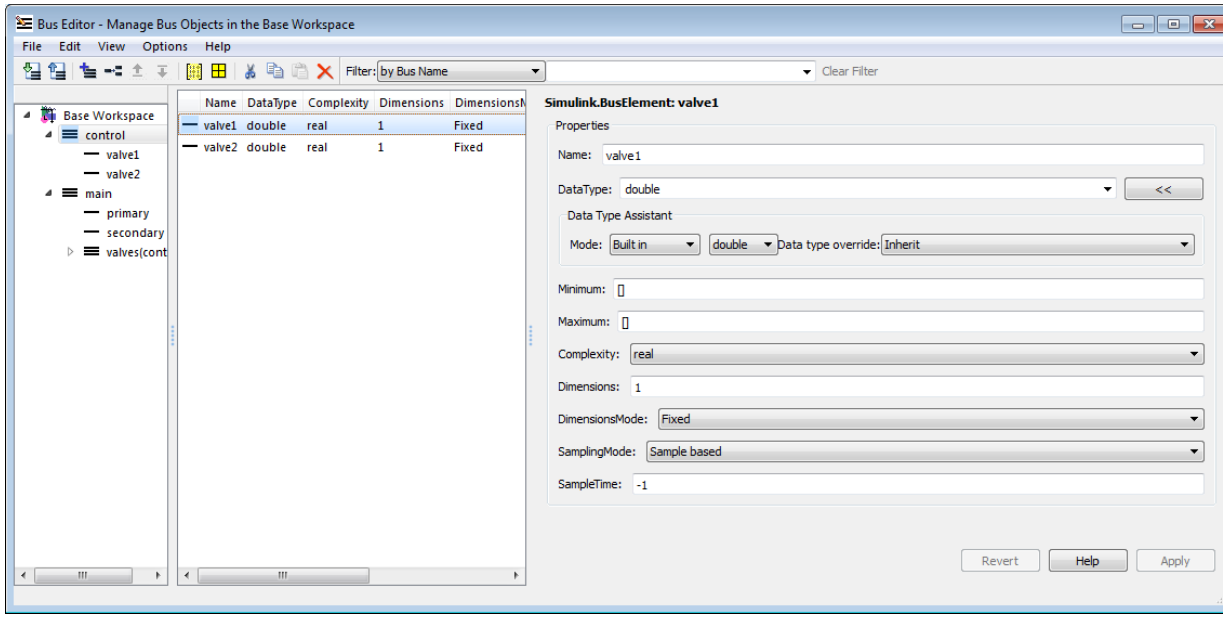
The Bus Editor is similar to the Model Explorer (which can display bus objects but cannot edit them) and uses the same three panes to display bus objects:

- **Hierarchy pane** (left) — Displays the bus objects defined in the base workspace
- **Contents pane** (center) — Displays the elements of the bus object selected in the Hierarchy pane
- **Dialog pane** (right) — Displays for editing the current selection in the Contents or Hierarchy pane

Items that appear in the Hierarchy pane or the Contents pane have Context menus that provide immediate access to the capabilities most likely to be useful with that item. The contents of an item's Context menu depend on the item and the current state within the Bus Editor. All Context menu options are also available from the menu bar and/or the toolbar. Right-click any item in the Hierarchy or Contents pane to see its Context menu.

Hierarchy Pane

If no bus objects exist in the base workspace, the Hierarchy pane shows only **Base Workspace**, which is the root of the hierarchy of bus objects. The Bus Editor then looks as shown in the previous figure. As you create or import bus objects, they appear in the Hierarchy Pane as nodes subordinate to **Base Workspace**. The bus objects appear in alphabetical order. The next figure shows the Bus Editor with two bus objects, `control` and `main`, defined in the base workspace:



The Hierarchy pane displays each bus object as an expandable node. The root of the node displays the name of the bus object, and (if the bus contains any elements) a button for expanding and collapsing the node. Expanding a bus node displays named subnodes that represent the bus's top-level elements. In the preceding figure, both bus objects are fully expanded , and `control` is selected.

Contents Pane

Selecting any top-level bus object in the Hierarchy Pane displays the object's elements in the Contents pane. In the previous figure, the elements of bus object `control`, `valve1` and `valve2`, appear. Each element's properties appear to the right of the element's

name. These properties are editable, and you can edit the properties of multiple elements in one operation, as described in “Editing in the Contents Pane” on page 63-46.

Dialog Pane

When a bus object is selected in the Hierarchy pane, or a bus object or element is selected in the Contents pane, the properties of the selected item appear in the Dialog pane. In the previous figure, `valve1` is selected in the Contents pane, so the Dialog pane shows its properties. These properties are editable, and changes can be reverted or applied using the buttons below the Dialog pane, as described in “Editing in the Dialog Pane” on page 63-48.

Filter Boxes

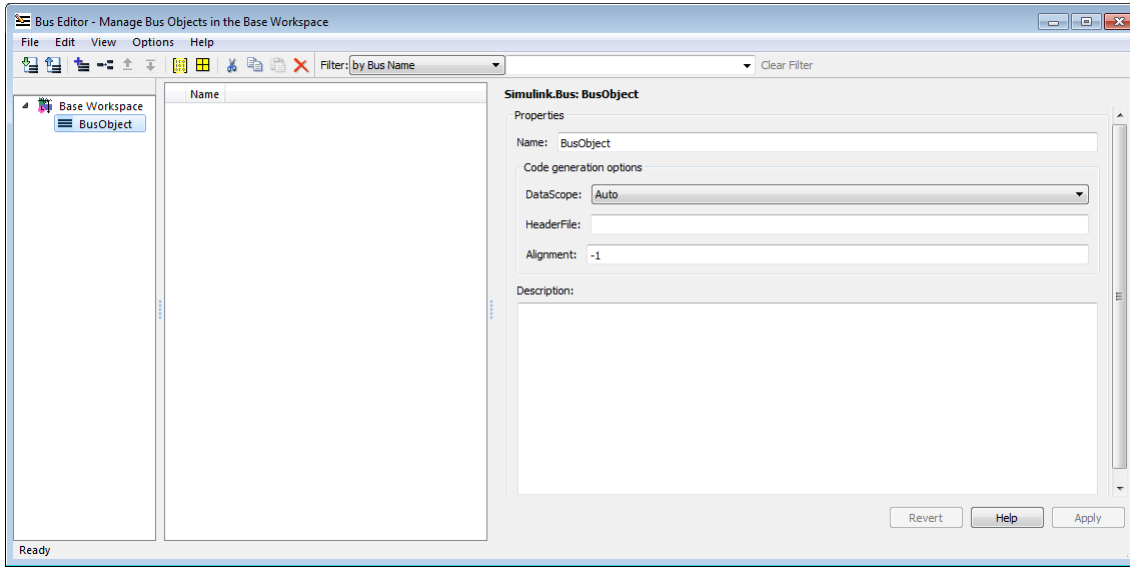
By default, the Bus Editor displays all bus objects that exist in the base workspace. Where a model contains large numbers of bus objects, seeing them all at the same time can be inconvenient. To facilitate working efficiently with large collections of bus objects, you can use the **Filter** boxes, to the right of the iconic tools in the toolbar, to show a selected subset of bus objects. See “Filter Displayed Bus Objects” on page 63-58 for details.

Create Bus Objects

To use the Bus Editor to create a new bus object in the base workspace:

1. Choose **File > Add Bus**.

   A new bus object with a default name and properties is created immediately in the base workspace. The object appears in the Hierarchy pane, and its default properties appear in the Dialog pane:



2 To specify the bus object name and other properties, in the Dialog pane:

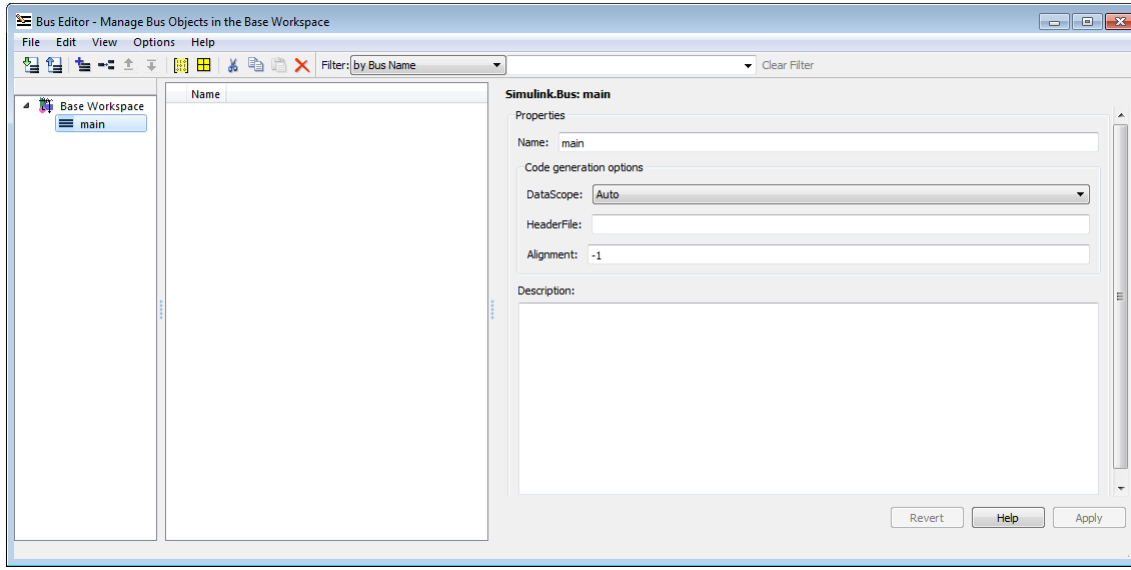
   a Specify the **Name** of the of the new bus object (or you can retain the default name). The name must be unique in the base workspace. See “Signal Names and Labels” on page 62-5 for guidelines for signal names.

   b Optionally, specify a C **Header file** that defines a user-defined type corresponding to this bus object. This header file has no effect on Simulink simulation; it is used only by Simulink Coder software to generate code.

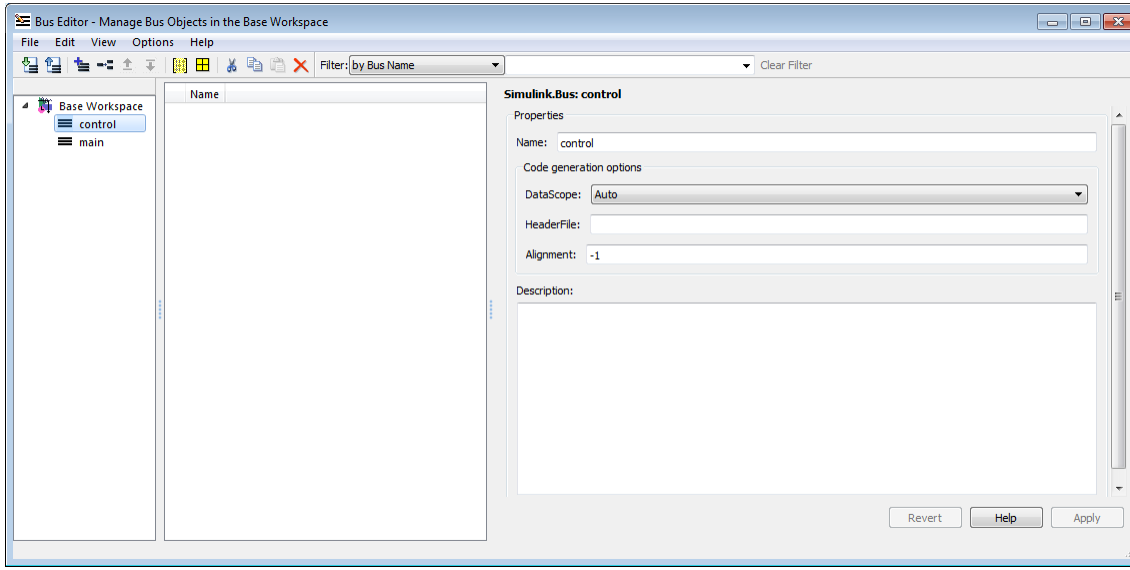
   c Optionally, specify a **Description** that provides information about the bus object to human readers. This description has no effect on Simulink simulation; it exists only for human convenience.

3 Click **Apply**.

The properties of the bus object on the base workspace change as specified. If you rename `BusObject` to `main`, the Bus Editor looks like this:



You can use **Add Bus** at any time to create a new bus object in the base workspace, then set the name and properties of the object as needed. You can intersperse creating bus objects and specifying their properties in any order. The hierarchy pane reorders as needed to display all bus objects in alphabetical order. If you add an additional bus object named `control`, the Bus Editor looks like this:



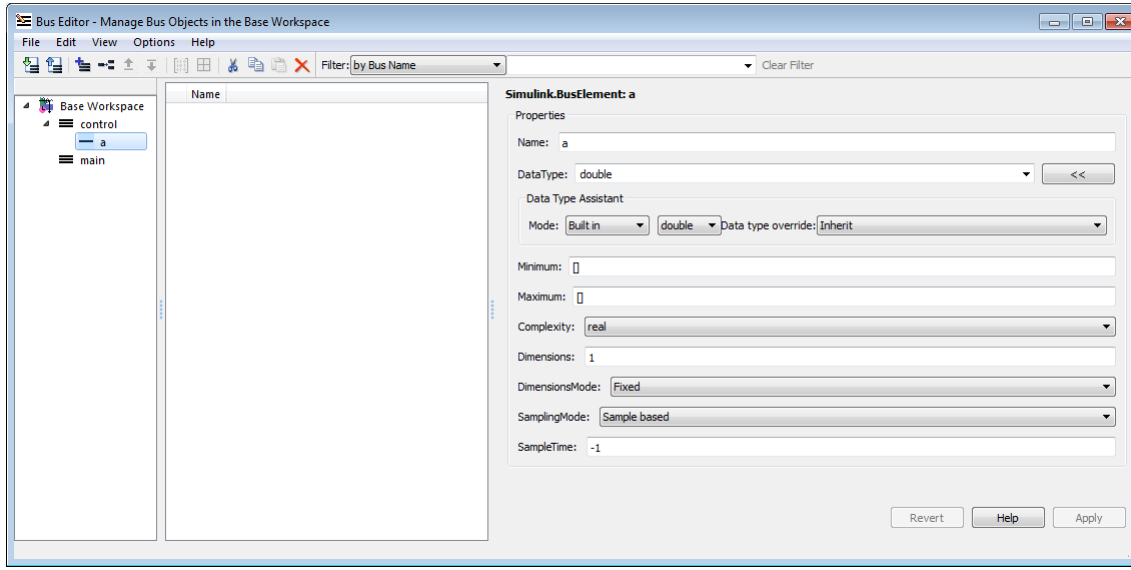
You can also use capabilities outside the Bus Editor to create new bus objects. Such objects do not appear in the Bus Editor until the next time its window is selected.

Create Bus Elements

Every bus element belongs to a specific bus. To create a new bus element:

1. In the Hierarchy pane, select the entity below which to create the new element. The entity can be a bus or a bus element. The new element will belong to the selected bus object, or to the bus object that contains the selected element. The previous figure shows the `control` bus object selected.
2. Choose **File > Add/Insert BusElement**.

   A new bus element with a default name and properties is created immediately in the applicable bus object. The object appears in the Hierarchy pane immediately below the previously selected entity, and its default properties appear in the Dialog pane:



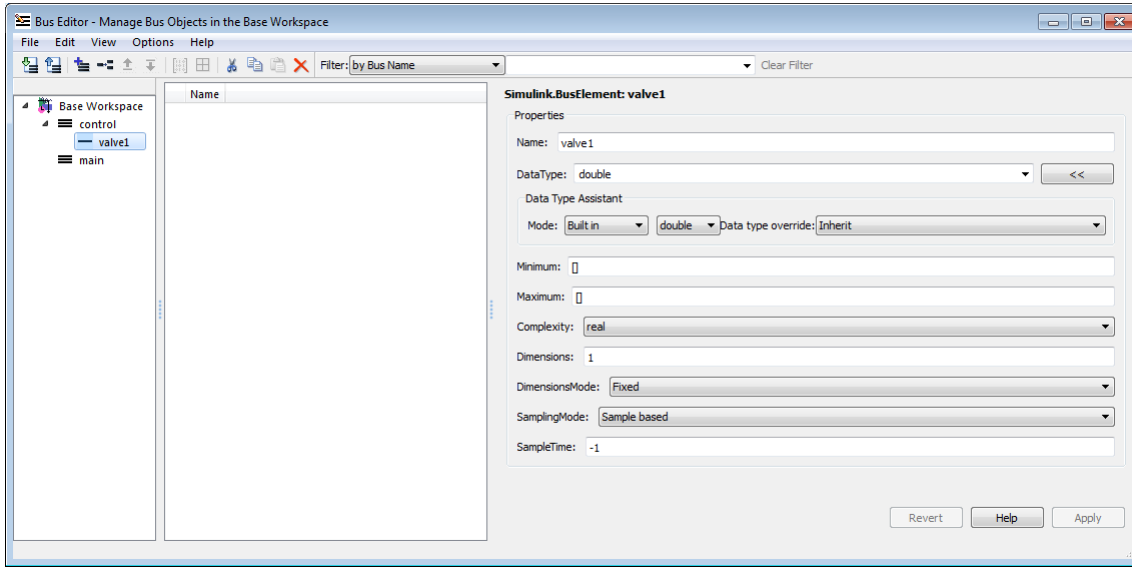
3 To specify the bus element name and other properties, in the Dialog pane:

   a Specify the **Name** of the of the new bus element (or you can retain the default name). The name must be unique among the elements of the bus object. See "Signal Names and Labels" on page 62-5 for guidelines for signal names.

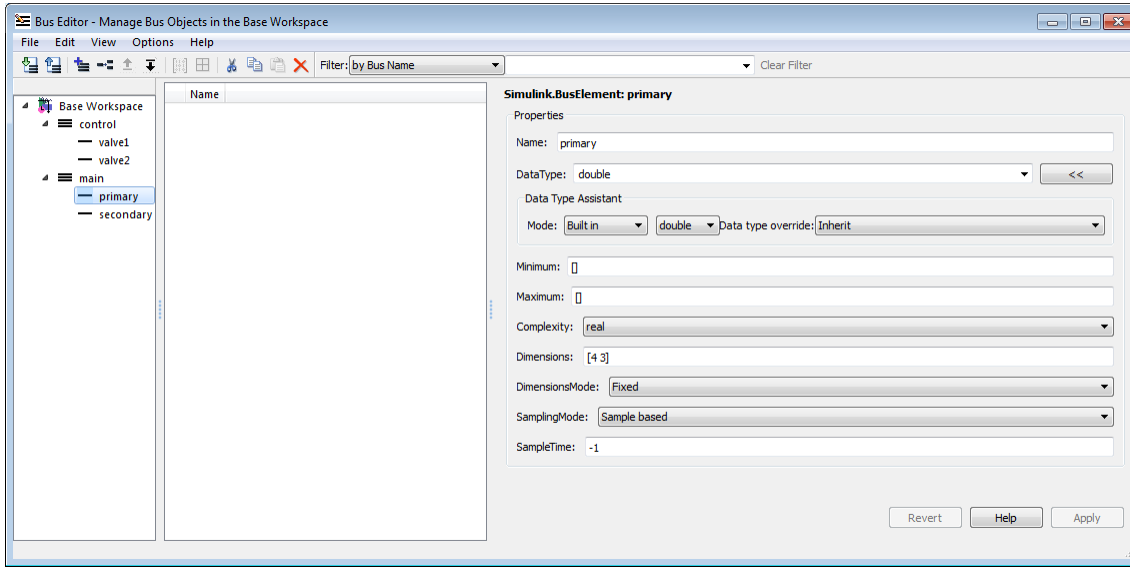
   b Specify the other properties of the element. The properties must match the properties of the corresponding signal within the bus exactly, and can be anything that a legal signal might have. The Data Type Assistant appears in the Dialog pane to help specify the element's data type. You can specify any available data type, including a user-defined data type.

4 Click **Apply**.

The properties of the bus element of the bus object in the base workspace change as specified. If you rename the new element `a` to `valve1`, the Bus Editor looks like this:



You can use **Add/Insert BusElement** at any time to create a new bus element in any bus object. You can intersperse creating bus objects and specifying their properties in any order. The order of the other bus elements in the bus object does not change when a new element is added. If you add element `valve2` to `control`, and `secondary` and `primary` to `main`, the Bus Editor looks like this:



You can also use capabilities outside the Bus Editor to add new bus elements to a bus object. Such an addition changes an existing bus object, so any new bus element appears immediately in the Bus Editor.

Nest Bus Definitions

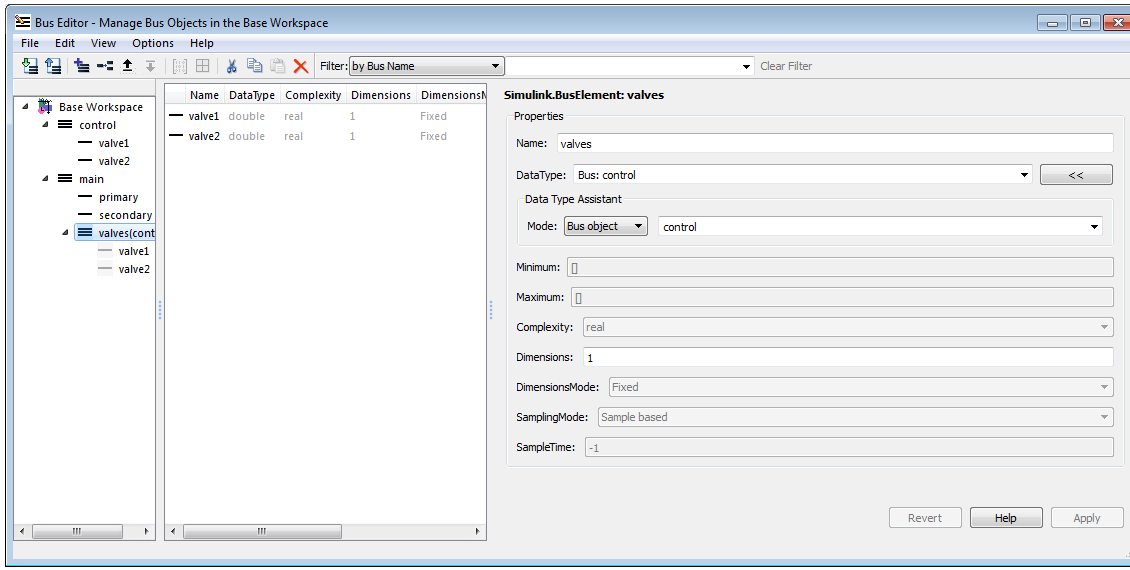
As described in “Nest Buses” on page 63-23, any signal in a bus can be another bus, which can in turn contain subordinate buses, and so on to any depth. Describing nested buses with bus objects requires nesting the bus definitions that the objects provide.

Every bus object inherently defines a data type whose properties are those specified by the object. To nest one bus definition in another, you assign to an element of one bus object a data type that is defined by another bus object. The element then represents a nested bus whose structure is given by the bus object that provides its data type.

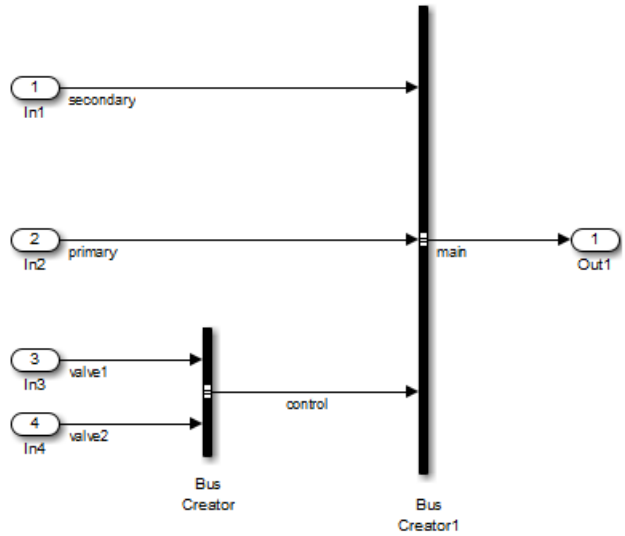
A data type defined by a bus object is called a *bus type*. Nesting buses by assigning bus types to elements, rather than by subordinating the bus objects that define the types, allows the same bus definition to be used conveniently in multiple contexts without unwanted interactions. To specify that an element of a bus object represents a nested bus definition:

1. Create a bus element to represent the nested bus definition, in the appropriate position under the containing bus object, and give the element the desired name. (You can also use an existing element.)
2. Use the Dialog pane to set the data type of the element to the name of a bus object. The Data Type Assistant shows the names of all available bus types. (You can also specify a nonexistent bus type and define the object later.)

In the preceding figure, if you add to bus object `main` a third element named `valves`, set the data type of `valves` to be `control` (the name of the other defined bus object) and expand the new element `valves`, the Bus Editor looks like this:



The bus object `main` shown in the Bus Editor now defines the same structure used by the bus signal `main` in the next figure:



The distinction between a bus object and the bus type that it defines can be useful for initially understanding how nested bus objects work and how the Bus Editor handles them. In other contexts, the distinction is mostly an implementation detail, and describing bus objects themselves as being nested is more convenient. The rest of this chapter follows that convention.

You can nest a bus object in as many different bus objects as desired, and as many times in the same bus object as desired. You can nest bus objects to any depth, but you cannot define a circular structure by directly or indirectly nesting a bus object within itself.

If you try to define a circular structure, the Bus Editor posts a warning and sets the data type of the element that would have completed the cycle to `double`. Click **OK** to dismiss the Notice and continue using the editor.

You can use the Hierarchy pane to explore nested bus objects by expanding the objects, but you cannot change any property of a bus object anywhere that it appears in nested form. To change the properties of a nested bus object, you must change the source object, which is accessible at the top level in the Hierarchy pane. You can jump from a nested bus object to its source object by selecting the nested object and choosing **Go to '*`element`*'** from its Context menu.

Change Bus Entities

You can use the Bus Editor to change and delete existing bus objects and elements at any time. All three panes allow you to change the entities that they display. Changes that create, reorder, or delete entities take effect immediately in the base workspace. Changes to properties take effect when you apply them, or can be canceled, leaving the properties unchanged. The Bus Editor does not provide an Undo capability.

The Bus Editor provides comprehensive GUI capabilities for changing bus entities. You can Cut, Copy, and Paste within and between panes in any way that has a legal result. The Hierarchy and Dialog panes provide a Context menu for the current selection. Pasting a Copied entity always creates a copy, as distinct from a pointer to the original. The Bus Editor automatically changes names when needed to avoid duplication.

Changes made outside the bus editor can affect the information on display within it. Any change to an existing bus object or bus element is visible immediately in the editor. Any change that creates or deletes a bus object becomes visible in the bus editor next time its window is selected.

Editing in the Hierarchy pane

You can select the root node **Base Workspace** and perform various operations, like export, cut, copy, paste, and delete. The operation simultaneously affects all bus objects displayed in the Hierarchy pane, but does not affect any that are invisible because a filter is in effect. See “Filter Displayed Bus Objects” on page 63-58 for details.

As you use the Bus Editor, the Hierarchy pane automatically reorders the bus objects it displays to maintain alphabetical order. This behavior cannot be changed. However, the elements under a bus object can appear in any order. To change that order, cut and paste elements as needed, or move elements up and down as follows:

1. Select the element to be moved.
2. Choose **Edit > Move Element Up** or **Edit > Move Element Down**.

You cannot Paste one bus object under another to create a nested bus object specification. To specify a nested bus, you must change the data type of a bus element to be the type of an existing bus object, as described in “Nest Buses” on page 63-23.

Editing in the Contents Pane

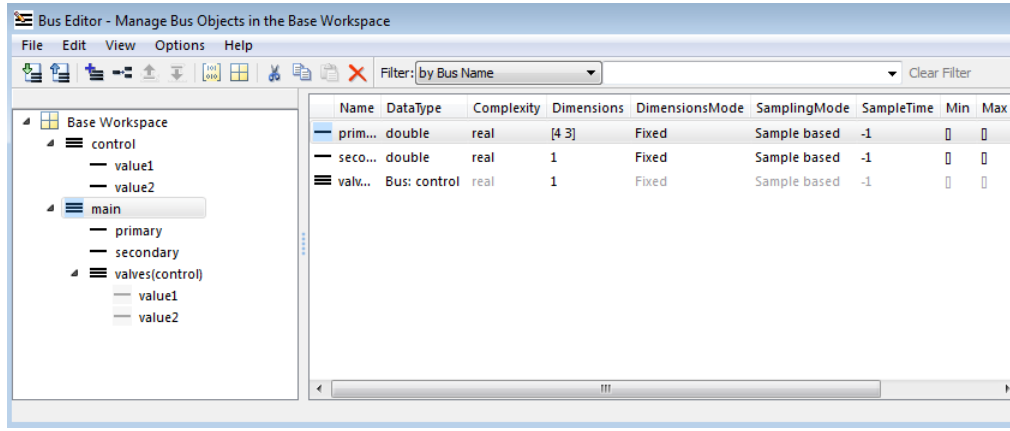
Selecting any top-level bus object in the Hierarchy pane displays the object's elements in the Contents pane. Each element's properties appear to the right of the element's name,

and can be edited. To change a property displayed in the Contents pane, click the value, enter a new value, then press **Return**.

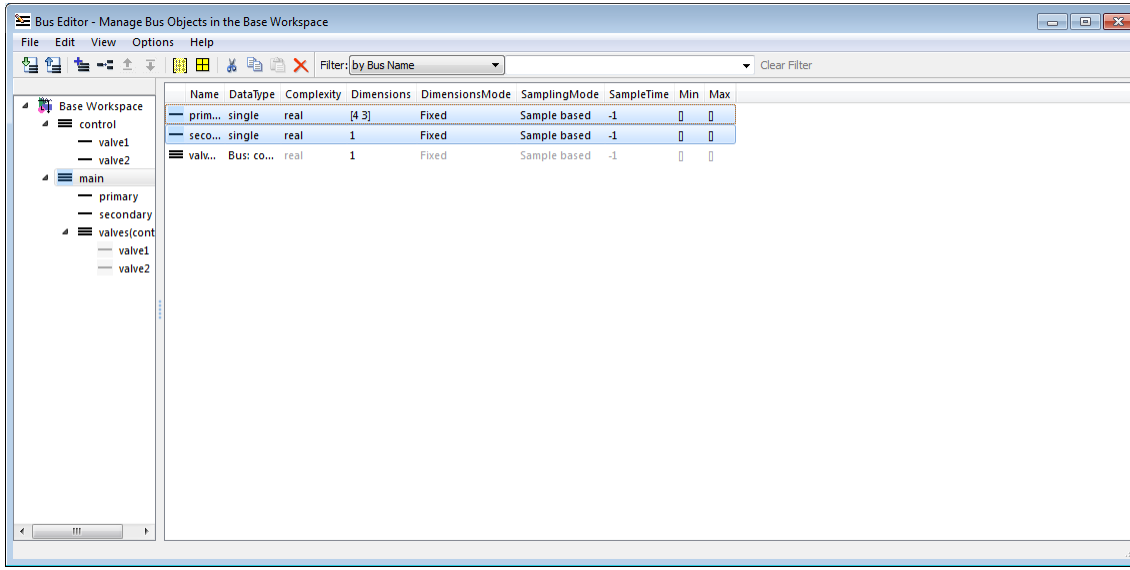
Choose **View > Dialog View** to hide the Dialog pane to provide more room to display properties in the Contents pane. Choose the command again to redisplay the Dialog pane.

You can use the mouse and keyboard to select multiple elements in the Contents pane. The selected entities need not be contiguous. You can then perform any operation that you could on a single entity selected in the pane, including operations performed with the Context menu. Clicking and editing a value in any selected element changes that value in them all.

The next figure shows the Bus Editor with **Dialog View** enabled, two elements selected in the Contents pane, and the **DataType** property selected for editing in the second element:

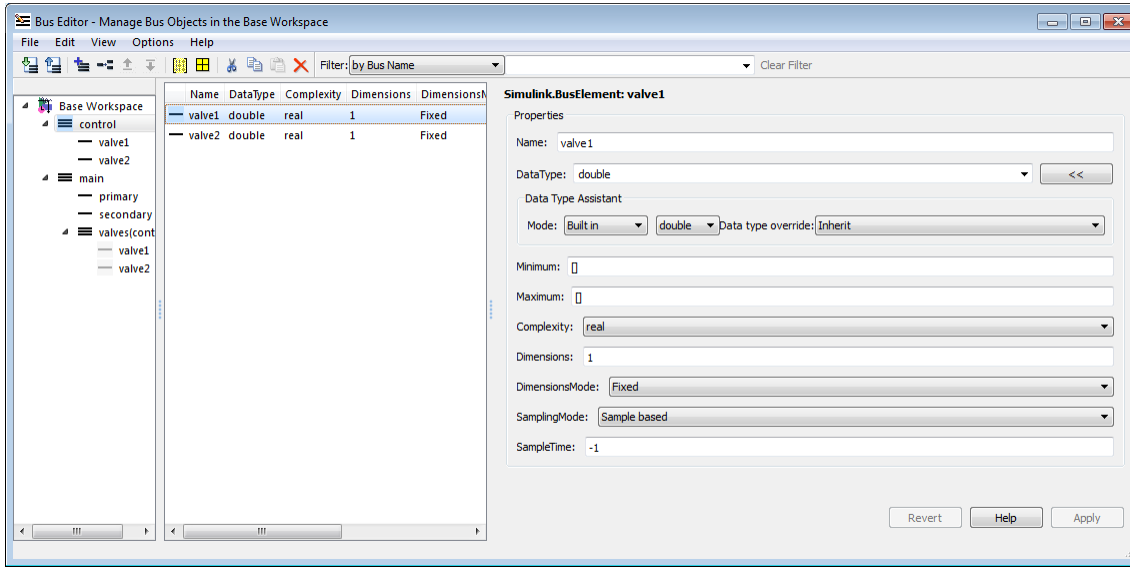


If you change the value of **DataType** to `single` and press Return, the value changes for both elements. The effect is the same no matter which element you edit in a multiple selection:

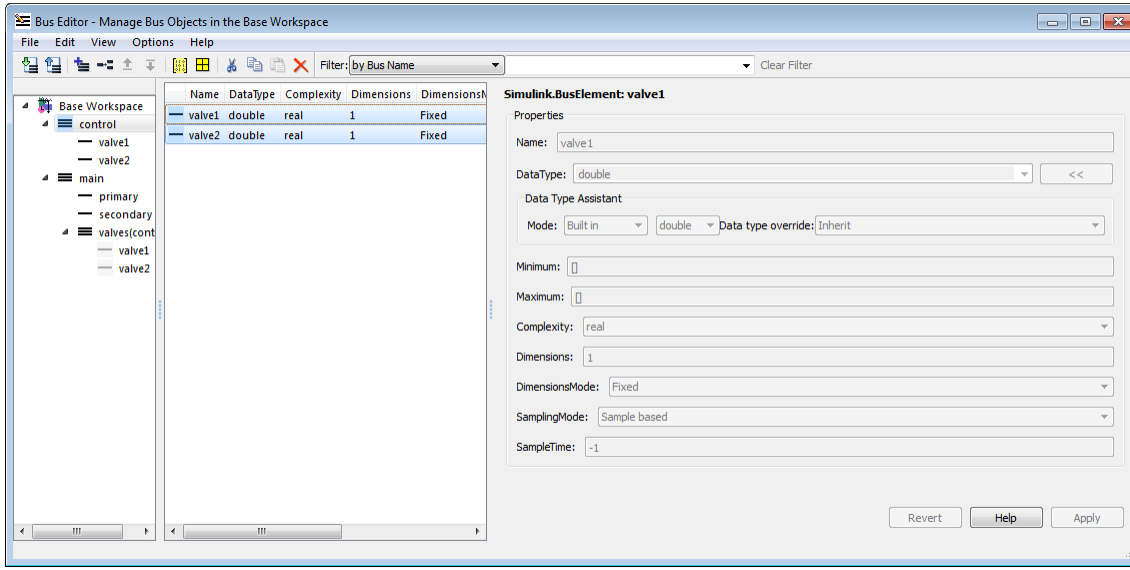


Editing in the Dialog Pane

When a bus object is selected in the Hierarchy pane, or a bus object or element is selected in the Contents pane, the properties of the selected item appear in the Dialog pane. In the next figure, `valve1` is selected in the Contents pane, so the Dialog pane shows its properties:



The properties shown in the Dialog pane are editable, and the pane includes the Data Type Assistant. Click **Apply** to save changes, or **Revert** to cancel them and restore the values that existed before any unapplied changes. You can edit only one element at a time in the Dialog pane. If multiple entities are selected in the Contents pane, all fields in the Dialog pane are grayed out:



If you use the Dialog pane to change any property of a bus entity, then navigate elsewhere without clicking either **Apply** or **Revert**, a query box appears by default. The query box asks whether to apply changes, ignore changes, or continue as if the navigation had not been tried. You can suppress this query for future operations by checking **Never ask me again** in the box, or by selecting **Options > Auto Apply/Ignore Dialog Changes**.

If you suppress the query, and thereafter navigate away from a change without clicking **Apply** or **Revert**, the Bus Editor automatically applies or discards changes, depending on which action you most recently chose in the box. You can re-enable the query box for future operations by deselecting **Options > Auto Apply/Ignore Dialog Changes**.

Export Bus Objects

Like all base workspace objects, bus objects are not saved with a model that uses them, but exist separately in a MATLAB code file or MAT-file. You can use the Bus Editor to export some or all bus objects to either type of file.

- If you export bus objects to a MATLAB code file, the Bus Editor asks whether to store them in object format or cell format (the default). Specify the desired format.

- If exporting would overwrite an existing MATLAB code file or MAT-file, a confirmation dialog box appears. Confirm the export or cancel it and try a different filename.

To export all bus objects from the base workspace to a file:

1. In the Bus Editor, choose **File > Export to File**.

   The Export dialog box appears.
2. Specify the desired name and format of the export file.
3. Click **Save**.

   All bus objects, and nothing else, are exported to the specified file in the specified format.

To export only selected bus objects from the base workspace to a file:

1. Select a bus object in the Hierarchy pane, or one or more bus objects in the Contents pane.
2. Right-click to display the Context menu.
3. Choose **Export to File** to export only the selected bus objects, or **Export with Related Bus Objects to File** to also export any nested bus objects used by the selected objects.
4. Use the Export dialog box to export the selected bus object(s).

Clicking the **Export** icon in the toolbar is equivalent to choosing **File > Export**, which exports all bus objects whether or not any are selected.

Customizing Bus Object Export

You can customize bus object export by providing a custom function that writes the exported objects to something other than the default destination, a MATLAB code file or MAT-file stored in the file system. For example, the exported bus objects could be saved as records in a corporate database. See “Customize Bus Object Import and Export” on page 63-65 for details.

Import Bus Objects

You can use the Bus Editor to import the definitions in a MATLAB code file or MAT-file to the base workspace. Importing the file imports the complete contents of the file, not

just any bus objects that it contains. If you import a file not exported by the Bus Editor, be careful that it does not contain unwanted definitions previously exported from the base workspace or created programmatically.

To import bus objects from a file to the base workspace:

1. Choose **File > Import into Base Workspace**.
2. Use the Open File dialog box to navigate to and import the desired file.

Before importing the file, the Bus Editor posts a warning that importing the file will overwrite any variable in the base workspace that has the same name as an entity in the file. Click **Yes** or **No** as appropriate. The imported bus objects appear immediately in the editor. You can also use capabilities outside the Bus Editor to import bus objects. Such objects do not appear in the Bus Editor until the next time its window becomes the current window.

Customizing Bus Object Import

You can customize bus object import by providing a custom function that imports the objects from something other than the default source, a MATLAB code file or MAT-file stored in the file system. For example, the bus objects could be retrieved from records in a corporate database. See "Customize Bus Object Import and Export" on page 63-65 for details.

Close the Bus Editor

To close the Bus Editor, choose **File > Close**. Closing the Bus Editor neither saves nor discards changes to bus objects, which remain unaffected in the base workspace. However, if you also close MATLAB without saving changes to bus objects, the changes will be lost. To save bus objects without saving other base workspace contents, use the techniques described in "Export Bus Objects" on page 63-50. You can also save bus objects using any MATLAB technique that saves the contents of the base workspace, but the resulting file will contain everything in the base workspace, not just bus objects.

You can configure the Bus Editor so that closing it posts a reminder to save bus objects. To enable the reminder, select **Options > Always Warn Before Closing**. When this option is selected and you try to close the Bus Editor, a reminder appears that asks whether the editor should save bus objects before closing. Click **Yes** to save bus objects and close, **No** to close without saving bus objects, or **Cancel** to dismiss the reminder and continue in the Bus Editor. You can disable the reminder by deselecting **Options > Always Warn Before Closing**.

Store and Load Bus Objects

In this section...
“Data Dictionary” on page 63-54
“MATLAB Code Files” on page 63-54
“MATLAB Data Files (MAT-Files)” on page 63-55
“Database or Other External Source Files” on page 63-55

You can store bus object objects in a variety of ways.

Format	When to Use
In a data dictionary	For large model componentization
As a MATLAB code file	For traceability and model differencing using MATLAB code
As a MATLAB data file (MAT-file)	For faster bus loading and saving
In a database or other external data source	For comparing bus interface information with design documents stored in an external data source.

Data Dictionary

You can use the Model Explorer to create a new data dictionary that includes bus objects and link it to a model. For details, see “Migrate Single Model to Use Dictionary” on page 61-5.

MATLAB Code Files

You can read and save bus data with MATLAB code files.

To save all bus objects (instances of the `Simulink.Bus` class) in the MATLAB base workspace to a MATLAB code file, use *one* of the following approaches:

- Use the Bus Editor (see “Export Bus Objects” on page 63-50 and “Import Bus Objects” on page 63-51).
- From the MATLAB command line, use the `Simulink.Bus.save` command.

To save variables from the base workspace to a MATLAB code file, use the `Simulink.saveVars` command. The file containing the variables is formatted to be easily understood and editable. Running the file restores the saved variables to the base workspace.

For traceability, consider using a clearly named separate file for each model.

MATLAB Data Files (MAT-Files)

You can load bus objects in MATLAB data files (MAT-files), using *one* of the following approaches:

- Use the Bus Editor (see "Export Bus Objects" on page 63-50 and "Import Bus Objects" on page 63-51).
- From the MATLAB command line, use the `load` command.

Loading large data from MAT-files is faster than loading from MATLAB code files.

Database or Other External Source Files

You can capture bus interface information in a database or other external source, and use scripts and Database Toolbox™ functionality to read that information into MATLAB.

You can use `sl_customization.m` to customize the Bus Editor to import bus data from a database or other external source. For details, see "Customize Bus Object Import and Export" on page 63-65.

Related Examples

- "Map Bus Objects to Models" on page 63-56

Map Bus Objects to Models

As models become complex, you need to keep track of which models use which bus objects. From any model or bus object, you should be able to tell what component it needs or is needed by.

A model must load all of its bus objects before you execute the model. For automation and consistency across models, it is important to map bus objects to models.

- By identifying all of the bus objects a model needs, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a bus object, you can ensure that changes to a bus object do not cause unexpected changes in any of the models that use that bus object.

To map bus objects to models, consider:

- Including the bus objects in a data dictionary. You can link the data dictionary to one or more models. For details, see “Migrate Single Model to Use Dictionary” on page 61-5.
- Using Simulink Projects by:

  1. Serializing the files that contain the bus objects as part of a project
  2. Loading that data upon project open

  For details, see “Project Management”.
- Capturing the mapping information in an external data source, such as a database.

Use a Rigorous Naming Convention

Using a rigorous and standard naming convention for bus mapping information is a straightforward approach. For example, consider the model and data required for an actuator control function. You could name the model `Actuator` and name the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively. This naming convention makes it clear to what models a particular bus object is related, and vice versa.

Note that this approach can cause issues if the output from one model reference is fed directly to another model reference. In this case, the naming mismatch results in an error.

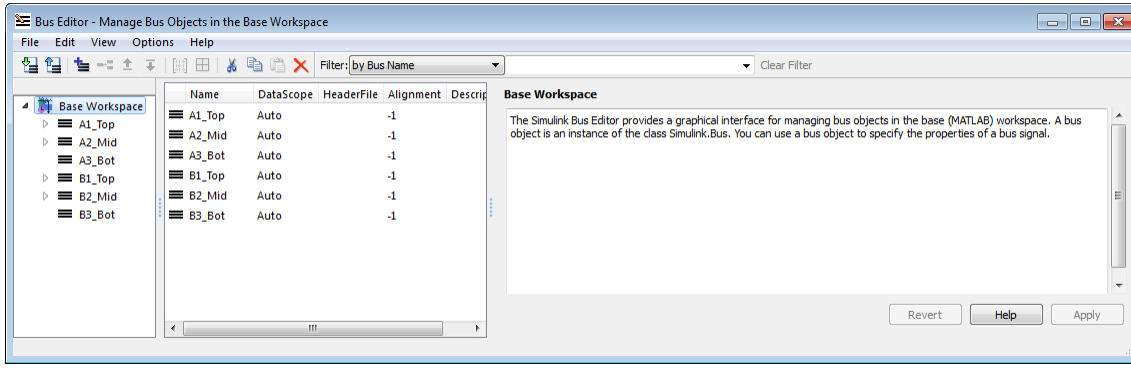
Filter Displayed Bus Objects

In this section...
“Filter by Name” on page 63-59
“Filter by Relationship” on page 63-60
“Change Filtered Objects” on page 63-62
“Clear the Filter” on page 63-63

By default, the Bus Editor displays all bus objects that exist in the base workspace, always in alphabetical order. When a model contains large numbers of bus objects, seeing them all at the same time can be inconvenient. To facilitate working efficiently with large collections of bus objects, you can set the Bus Editor to display only bus objects that:

- Have names that match a given string or regular expression
- Have a specified relationship to a bus object specified by name

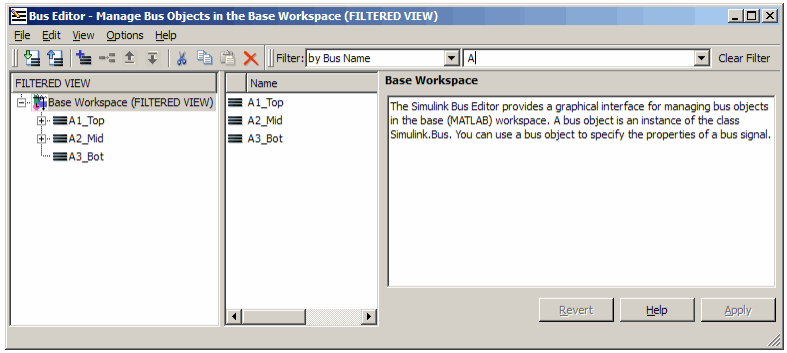
To set a filter, you specify values in the **Filter** boxes to the right of the tools in the toolbar. The left **Filter** box specifies the type of filtering. This box always appears, and is called the **Filter Type** box. Depending on the specified type of filtering, one or two boxes appear to the right of the **Filter Type** box. The next figure includes the **Filter** boxes (near the top of the dialog box) and shows that six bus objects exist in the Base Workspace:



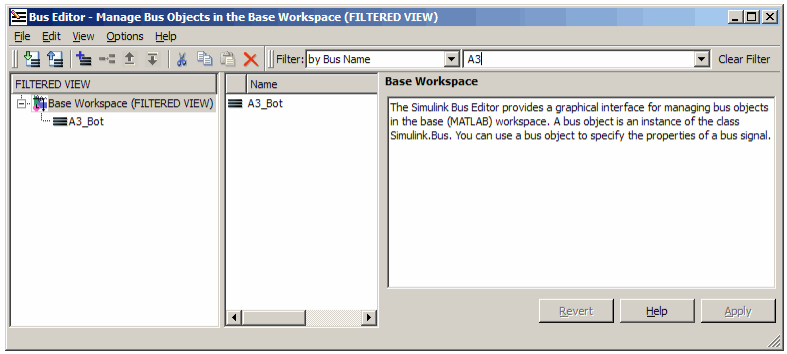
The bus objects shown form two disjoint hierarchies. `A1_Top` is the parent of `A2_Mid`, which is the parent of `A3_Bot`. Similarly, `B1_Top` > `B2_Mid` > `B3_Bot`. See “Nest Buses” on page 63-23 for information about bus object hierarchies.

Filter by Name

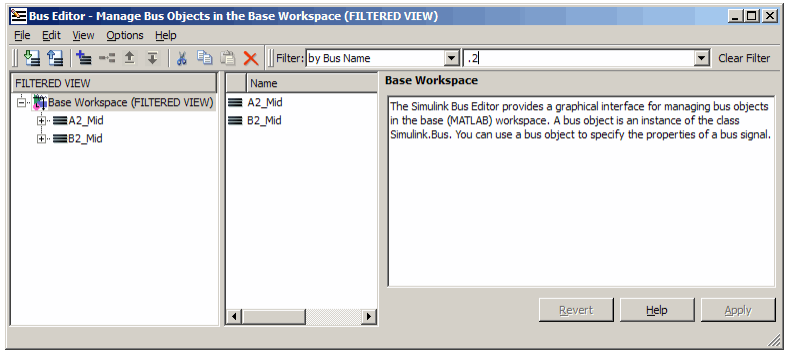
To filter bus objects by name, set the **Filter Type** box to `by Bus Name` (which is the default). The right **Filter** box is the **Object Name** box. Type any MATLAB regular expression (which can just be a string) into the **Object Name** box. As you type, the Bus Editor updates dynamically to show only bus objects whose names match the expression you have typed. The comparison is case-sensitive. For example, entering `A` displays:



Note that **FILTERED VIEW** appears in three locations, as shown in the preceding figure. This indicator appears whenever any filter is in effect. Entering the additional character `3` into the **Object Name** box displays:



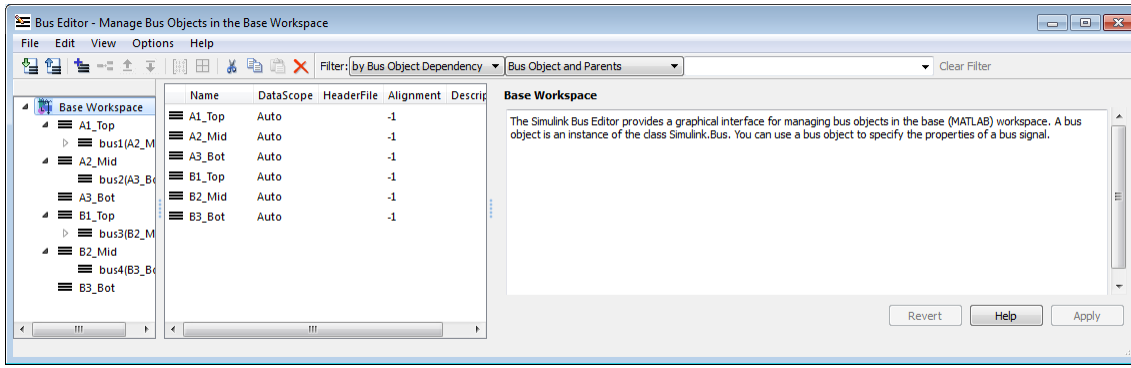
In a MATLAB regular expression, the metacharacter `dot` (.) matches any character, so entering `.2` displays:



See “Regular Expressions” for complete information about MATLAB regular expression syntax.

Filter by Relationship

To filter bus objects by relationship, set the **Filter Type** box to `by Bus Object Dependency`. A third **Filter** box, called the **Relationship** box, appears between the **Filter Type** box and the **Object Name** box. You may have to widen the Bus Editor to see all three boxes:



In the **Relationship** box, select the type of relationship to display. The options are:

- `Bus Object and Parents` — Show a specified bus object and all superior bus objects in the hierarchy (default)
- `Bus Object and Dependents` — Show a specified bus object and all subordinate bus objects in the hierarchy

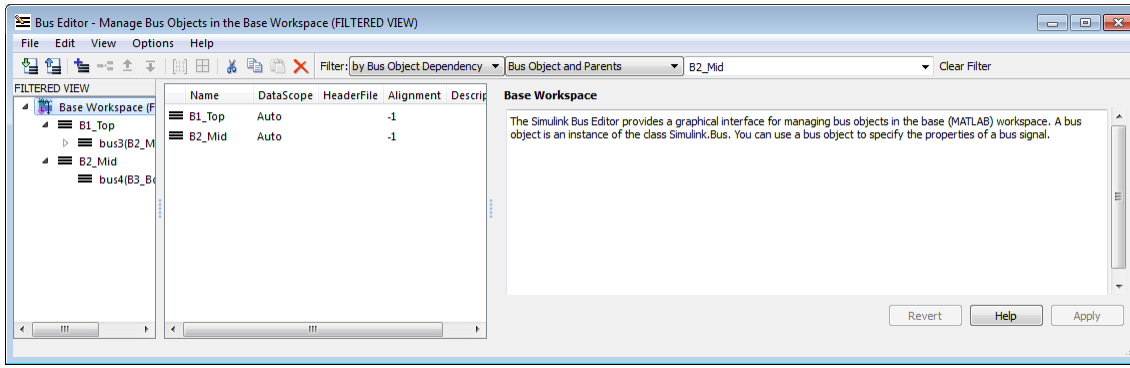
- `Bus Object and Related Objects` — Show a specified bus object and all superior and subordinate bus objects

In the **Object Name** box, specify a bus object by name. You can use the list to select any existing bus object name, or you can type a name. As you type, the editor:

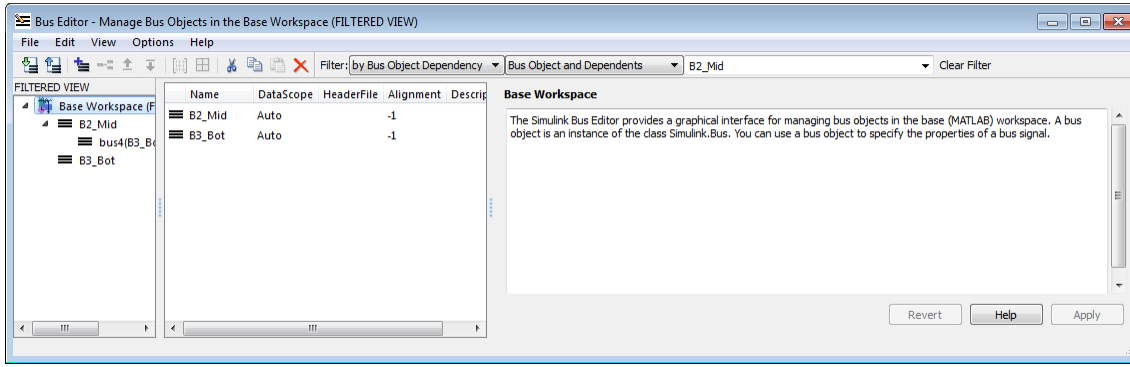
- Dynamically completes the field to indicate the first bus object that alphabetically matches what you have typed.
- Updates the display panes to show only that object and any objects that have the specified relationship to it.

When filtering by relationship, you must enter a string, not a regular expression, in the **Object Name** box. The match is case-sensitive. For example, assuming that `A1_Top` is the parent of `A2_Mid`, which is the parent of `A3_Bot` (as previously described) if you enter `B2` (or any leftmost substring that matches only `B2_Mid`) in the **Object Name** box, the Bus Editor displays the following for each of the three choices of relationship type:

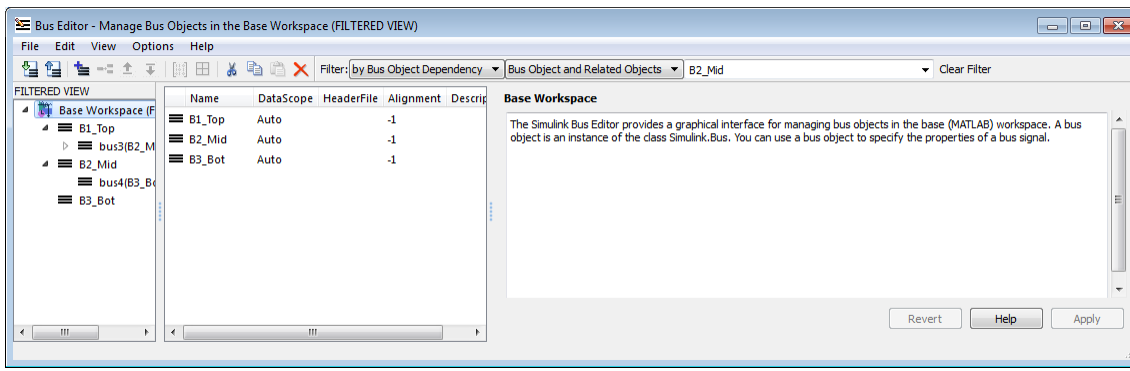
Bus Object and Parents



Bus Object and Dependents



Bus Object and Related Objects



Note that **FILTERED VIEW** appears in each the preceding figures, as it does when any filter is in effect.

Change Filtered Objects

You can work with any bus object that is visible in a filtered display exactly as you could in an unfiltered display. If you change the name or dependency of an object so that it no longer passes the current filter, the object vanishes from the display. Conversely, if some activity outside the Bus Editor changes a filtered object so that it passes the current filter, the object immediately becomes visible.

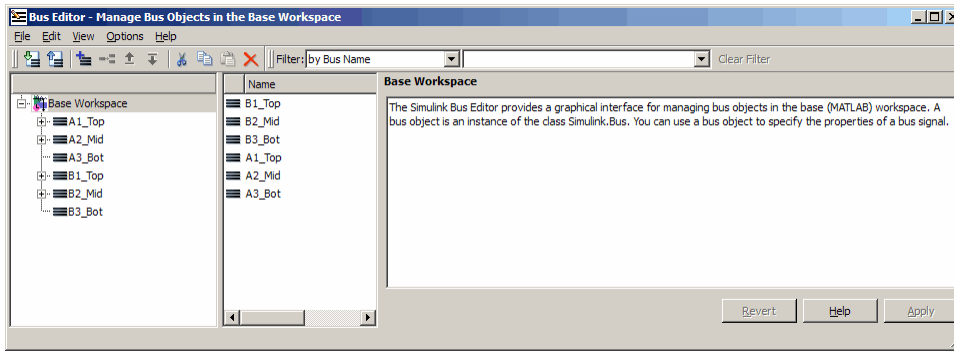
A new bus object created within the Bus Editor with a filter in effect may or may not appear, depending on the filter. If you create a new bus object but do not see it in the

editor, check the filter. The new object (whose name always begins with `BusObject`) may exist but be invisible. Bus objects created or imported using capabilities outside the Bus Editor are not visible until the Bus Editor window is next selected, regardless of whether a filter is in effect.

Operations performed on the root node **Base Workspace** in the Hierarchy pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a filter is in effect is unaffected by the operation. If you want to export all existing bus objects, be sure to clear any filter that may be in effect before performing the export.

Clear the Filter

To clear any filter currently in effect, click the **Clear Filter** button at the right of the Filter subpane, or press the **F5** key. The subpane reverts to its default state, in which all bus objects appear:



If you jump from a nested bus object to its source object by selecting the nested object and choosing **Go to '*`element`*'** from its Context menu, and the source object is invisible due to a filter, the Bus Editor automatically clears the filter and selects the source object. Jumping to an object that is already visible leaves the filter unchanged.

Customize Bus Object Import and Export

In this section...
“Prerequisites for Customization” on page 63-66
“Writing a Bus Object Import Function” on page 63-66
“Writing a Bus Object Export Function” on page 63-67
“Registering Customizations” on page 63-67
“Changing Customizations” on page 63-69

You can use the Bus Editor to import bus objects to the base workspace, as described in “Import Bus Objects” on page 63-51, and to export bus objects from the base workspace, as described in “Export Bus Objects” on page 63-50. By default, the Bus Editor can import bus objects only from a MATLAB code file or MAT-file, and can export bus objects only to a MATLAB code file or MAT-file, with the files stored somewhere that is accessible using an ordinary **Open** or **Save** dialog.

Alternatively, you can customize the Bus Editor's import and export commands by writing MATLAB functions that provide the desired capabilities, and registering these functions using the Simulink Customization Manager. When a custom bus object import or export function exists, and you use the Bus Editor to import or export bus objects, the editor calls the custom import or export function rather than using its default capabilities.

A customized import or export function can have any desired effect and use any available technique. For example, rather than storing bus objects in MATLAB code files or MAT-files in the file system, you could provide customized functions that store the objects as records in a corporate database, perhaps in a format that also meets other corporate data management requirements.

This section describes techniques for designing and implementing a custom bus object import or export function, and for using the Simulink Customization Manager to register such a custom function. The registration process establishes the custom import and export functions as callbacks for the Bus Editor **Import to Base Workspace** and **Export to File** commands, replacing the default capabilities of the editor.

Customizing the Bus Editor's import and export capabilities has no effect on any MATLAB or Simulink API function: it affects only the behavior of the Bus Editor. You can customize bus object import, export, or both. You can establish, change, and cancel

import or export customization at any time. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

Prerequisites for Customization

To perform bus object import or export customization, you must understand:

- The MATLAB language and programming techniques that you will need.
- Simulink bus object syntax. See "About Bus Objects" on page 63-27, `Simulink.Bus`, `Simulink.BusElement`, and "Nest Bus Definitions" on page 63-43.
- The proprietary format into which you will translate bus objects, and all techniques necessary to access the facility that stores the objects.
- Any platform-specific techniques needed to obtain data from the user, such as the name of the location in which to store or access bus objects.

The rest of the information that you will need, including all necessary information about the Simulink Customization Manager appears in this section. For complete information about the Customization Manager, see "Simulink Environment Customization".

Writing a Bus Object Import Function

A function that customizes bus import can use any MATLAB programming construct or technique. The function can take zero or more arguments, which can be anything that the function needs to perform its task. You can use functions, global variables, or any other MATLAB technique to provide argument values. The function can also poll the user for information, such as a designation of where to obtain bus object information. The general algorithm of a custom bus object import function is:

1. Obtain bus object information from the local repository.
2. Translate each bus object definition to a Simulink bus object.
3. Save each bus object to the MATLAB base workspace.

An example of the syntactic shell of an import callback function is:

```
function myImportCallBack
disp('Custom import was called!');
```

Although this function does not import any bus objects, it is syntactically valid and could be registered with the Simulink Customization Manager. A real import function would

somehow obtain a designation of where to obtain the bus object(s) to import; convert each one to a Simulink bus object; and store the object in the base workspace. The additional logic needed is enterprise-specific.

Writing a Bus Object Export Function

A callback function that customizes bus export can use any MATLAB programming construct or technique. The function must take one argument, and can take zero or more additional arguments, which can be anything that the function needs to perform its task. When the Bus Editor calls the function, the value of the first argument is a cell array containing the names of all bus objects selected within the editor to be exported. You can use functions, global variables, or any other MATLAB technique to provide values for any additional arguments. The general algorithm of a customized export function is:

1. Iterate over the list of object names in the first argument.
2. Obtain the bus object corresponding to each name.
3. Translate the bus object to the proprietary syntax.
4. Save the translated bus object in the local repository.

An example of the syntactic shell of such an export callback function is:

```
function myExportCallBack(selectedBusObjects)
disp('Custom export was called!');
for idx = 1:length(selectedBusObjects)
    disp([selectedBusObjects{idx} ' was selected for export.']);
end
```

Although this function does not export any bus objects, it is syntactically valid and could be registered. It accepts a cell array of bus object names, iterates over them, and prints each name. A real export function would use each name to retrieve the corresponding bus object from the base workspace; convert the object to proprietary format; and store the converted object somewhere. The additional logic needed is enterprise-specific.

Registering Customizations

To customize bus object import or export, you provide a *customization registration function* that inputs and configures the Customization Manager whenever you start the Simulink software or subsequently refresh Simulink customizations. The steps for using a customization registration function are:

1. Create a file named `sl_customization.m` to contain the customization registration function (or use an existing customization file).
2. At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument will be the Customization Manager.
3. Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized bus object import and export functions.
4. If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently-used locations are `matlabroot` and the current working directory; or you may want to extend the search path.

A simple example of a customization registration function is:

```
function sl_customization(cm)
disp('My customization file was loaded.');
cm.BusEditorCustomizer.importCallbackFcn = @myImportCallBack;
cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallBack(x);
```

When the Simulink software starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. The software loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the previous customization function will display a message (which an actual function probably would not) and establish that the Bus Editor uses a function named `myImportCallBack()` to import bus objects, and a function named `myExportCallBack(x)` to export bus objects.

The function corresponding to a handle that appears in a callback registration need not be defined when the registration occurs, but it must be defined when the Bus Editor later calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of any additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m` except when it starts up or refreshes customizations, so any changes to functions in the customization file will be ignored until one of those events occurs. By contrast, changes to other MATLAB code files on the MATLAB path take effect immediately.

Changing Customizations

You can change the handles established in the `sl_customization` function by changing the function to specify the changed handles, saving the function, then refreshing customizations by executing:

```
sl_refresh_customizations
```

The Simulink software then traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting the appropriate `BusEditorCustomizer` element to `[]` in the `sl_customization` function, then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```
cm.BusEditorCustomizer.clear
```

where `cm` was previously set to a customization manager object (see "Registering Customizations" on page 63-67).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately unless they are in the `sl_customization.m` file itself, in which case they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

Use Buses for Inports and Outports

In this section...
"Use Buses with Root-Level Inports" on page 63-71
"Use Buses with Root-Level Outports" on page 63-71
"Buses for Atomic Subsystem Nonvirtual Inports" on page 63-72
"Buses with Model Referencing" on page 63-74

For information about using buses as inputs to, or outputs from, a referenced model, see "Bus Data Crossing Model Reference Boundaries" on page 63-119.

Use Buses with Root-Level Inports

To have a root-level Inport block in a model that does not specify a bus object produce a bus signal, in the Inport block parameters dialog box:

- Set **Data type** to `Bus: <object name>`.
- Replace `<object name>` with the name of the bus object name that defines the bus that the Inport produces.

For more information, see "Import Bus Data to Top-Level Input Ports" on page 59-147.

Use Buses with Root-Level Outports

A root level Outport of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

To have a root-level Outport of a model accept a bus signal that contains mixed data types, in the Outport block parameters dialog box:

- Set **Data type** to `Bus: <object name>`.
- Replace `<object name>` with the name of the bus object name that defines the bus that the Outport produces.

If the bus signal in a top-level model in a model reference hierarchy is virtual, the signal is converted to nonvirtual, as described in "Automatic Bus Conversion" on page 63-16. For background information, see "Bus Objects" on page 63-27 more information.

Buses for Atomic Subsystem Nonvirtual Inports

By default, an Inport block is a virtual block and accepts a bus as input. However, an Inport block is nonvirtual if:

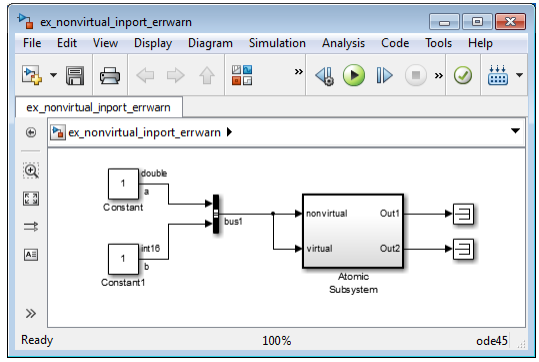
- The Inport block is in an atomic subsystem.
- The signal or any of its elements (if the signal is a bus) are directly connected to the output of the subsystem.

The Inport block can accept a bus if one these conditions is true:

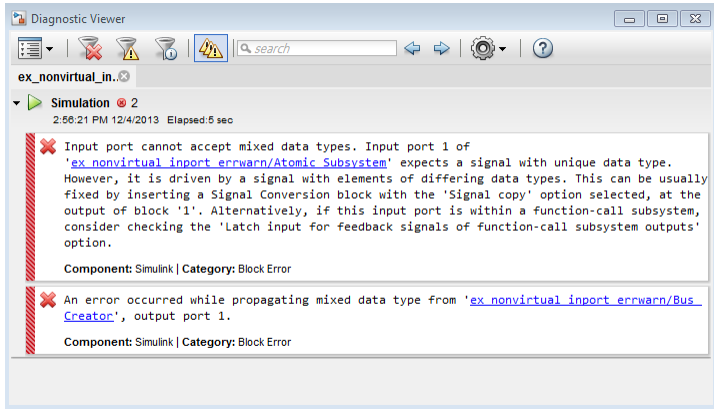
- All elements of the bus can be converted to a vector (for example, all the elements must have the same data type).
- The bus is a nonvirtual bus.

If the bus elements are of differing data types, attempting to simulate the model causes the Simulink software to halt the simulation and display an error message. To avoid this problem without changing the semantics of your model, insert a `Signal Conversion` block between the Inport block and the Outport block to which it was originally connected.

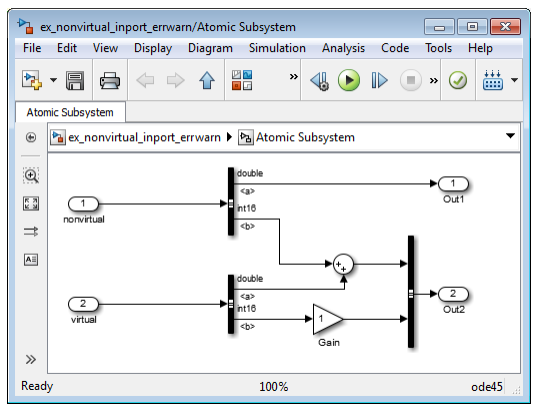
For example, the following model, which includes an atomic subsystem, does not simulate.



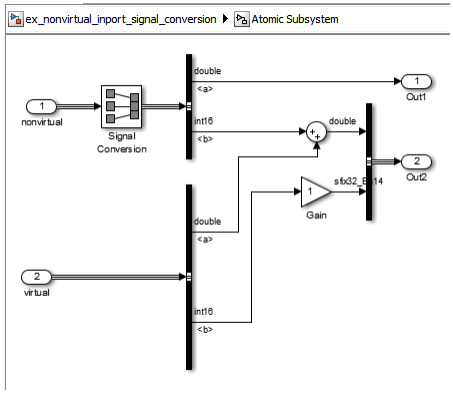
Starting the simulation generates the following error messages:



Opening the subsystem reveals that in this model, the Inport block labeled `nonvirtual` is nonvirtual because it resides in an atomic subsystem and one of its bus elements (labeled `a`) is directly connected to one of the subsystem's outputs. Further, the bus (`bus1`) connected to the subsystem's inputs has elements of differing data types. As a result, you cannot simulate this model.



To break the direct connection to the subsystem's output, insert a Signal Conversion block. Set the Signal Conversion block **Output** parameter to `Signal copy`. Inserting the Signal Conversion block enables the Simulink software to simulate the model.



Buses with Model Referencing

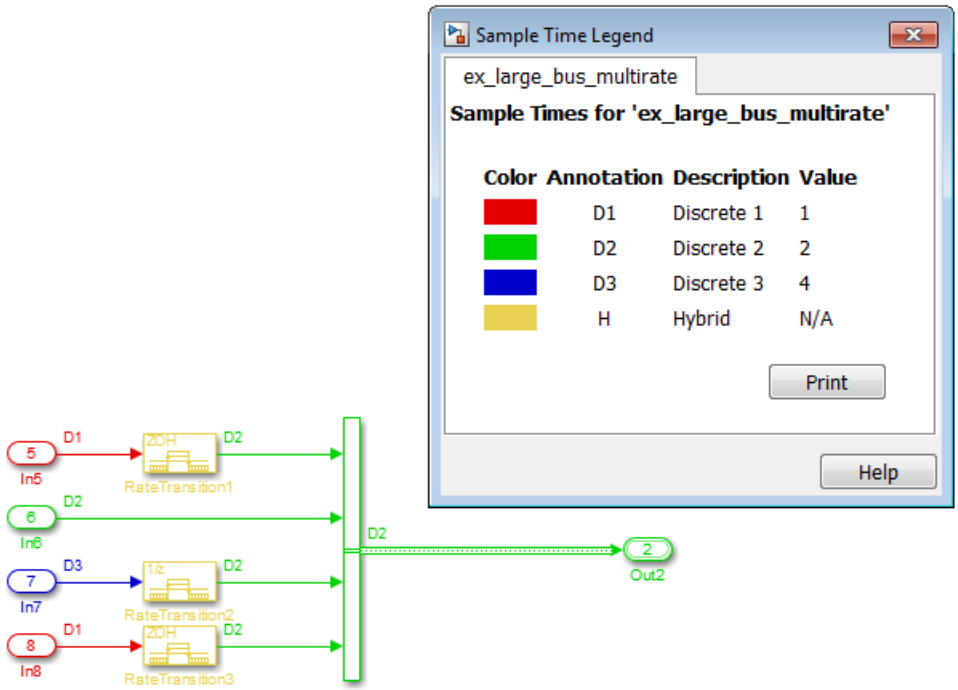
Use Different Sample Times for Signal Elements in a Bus

You create buses in a model to package multiple signal lines into a single line or to produce structures in the code that you generate from the model. For basic information about buses, see “Buses” on page 63-6.

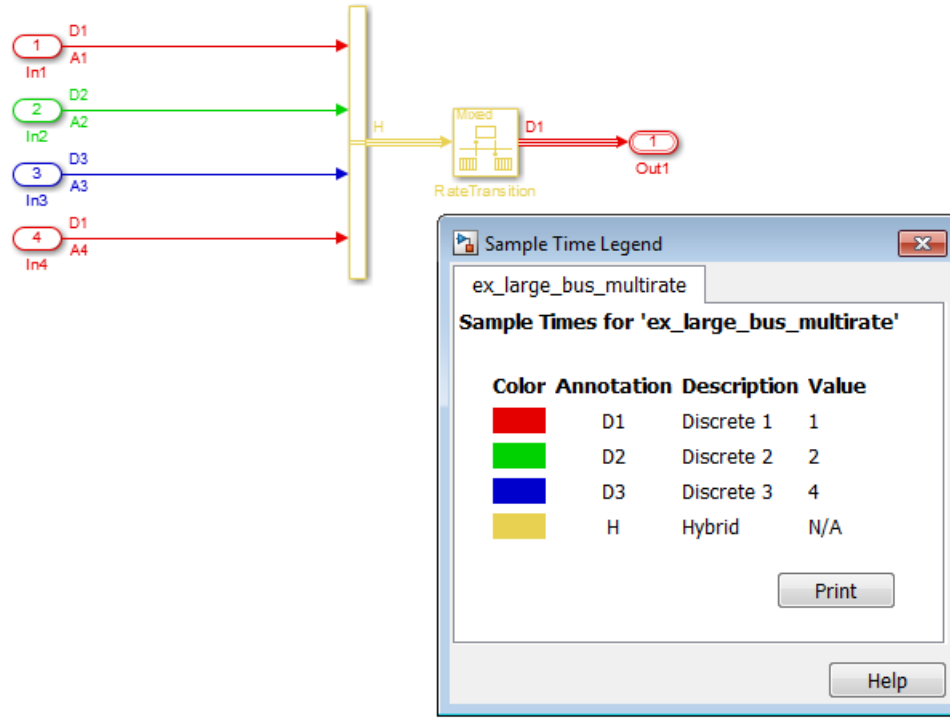
The technique that you use to combine signals that use different sample times depends on the virtuality of the bus. For basic information about virtual and nonvirtual buses, see “Virtual and Nonvirtual Buses” on page 63-14.

The signal elements in a nonvirtual bus must all have the same sample time. Upstream of the `Bus Creator` block, use `Rate Transition` blocks to apply the same sample time to each signal element.



The signal elements in a virtual bus can have different sample times.

However, some blocks, such as root-level `Outport` blocks, automatically convert virtual buses to nonvirtual buses. In this case, you can use a single `Rate Transition` block after a `Bus Creator` block to transition all of the signal elements to a single sample time.



For more information about automatic conversion of virtual buses to nonvirtual buses, see “Automatic Bus Conversion” on page 63-16.

Specify Sample Times for Signal Elements

To control the sample time of each signal element in a bus, specify the sample time in the block dialog box of the block that generates the signal element.

If you create a `Simulink.Bus` object to control the characteristics of the signal elements, it is a best practice to use the default value, `-1`, for the **SampleTime** property of each signal element in the bus object.

Specify Initial Conditions for Bus Signals

In this section...
"Bus Signal Initialization" on page 63-78
"Create Initial Condition (IC) Structures" on page 63-79
"Three Ways to Initialize Bus Signals Using Block Parameters" on page 63-84
"Initialize Arrays of Buses" on page 63-87
"Setting Diagnostics to Support Bus Signal Initialization" on page 63-90

Bus Signal Initialization

Bus signal initialization is a special kind of signal initialization. For general information about initializing signals, see "Initialize Signals and Discrete States" on page 62-47.

Bus signal initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus signal. By default, the initial value for a bus element is the ground value (represented by `0`). Bus initialization, as described in this section, involves specifying nonzero initial conditions (ICs).

You can use bus signal initialization features to:

- Specify initial conditions for signals that have different data types
- Apply a different initial condition for each signal in the bus
- Specify initial conditions for a subset of signals in a bus without specifying initial conditions for all the signals
- Use the same initial conditions for multiple blocks, signals, or models

Blocks that Support Bus Signal Initialization

You can initialize bus signal values that input to a block, if that block meets both of these conditions:

- It has an initial value or initial condition block parameter
- It supports bus signals

The following blocks support bus signal initialization:

- Data Store Memory
- Memory
- Merge
- Outport (when the block is inside a conditionally executed context)
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block and the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

Initialization Is Not Supported for Bus Signals with Variable-Size or Frame-Based Elements

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

Workflow for Initializing Bus Signals Using Initial Condition Structures

You need to set up your model properly to use initial condition structures to initialize bus signals. The general workflow involves the tasks listed in the following table. You can vary the order of the tasks, but before you update the diagram or run a simulation, you need to ensure your model is set up properly.

Task	Documentation
Define an IC structure	“Create Initial Condition (IC) Structures” on page 63-79
Use an IC structure to specify a nonzero initial condition.	“Three Ways to Initialize Bus Signals Using Block Parameters” on page 63-84
Set Configuration Parameters dialog box diagnostics	“Setting Diagnostics to Support Bus Signal Initialization” on page 63-90

Create Initial Condition (IC) Structures

You can create partial or full IC structures to represent initial values for a bus signal. Create an IC structure by either:

- Defining a MATLAB structure in the MATLAB base or Simulink model workspace
- Specifying an expression that evaluates to a structure for the initial condition parameter in the Block Parameters dialog box for a block that supports bus signal initialization

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

Full and Partial IC Structures

A full IC structure provides an initial value for every element of a bus signal. This IC structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

A partial IC structure provides initial values for a subset of the elements of a bus signal. If you use a partial IC structure, during simulation, Simulink creates a full IC structure to represent all of the bus signal elements, assigning the respective ground value to each element for which the partial IC structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

Match IC Structure Values to Corresponding Bus Element Data Characteristics

The field that you specify in an IC structure must match the following data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the IC structure, define the value to initialize that bus element to be a real [2x2] double array.

You must explicitly specify fields in the IC structure for every bus element that has an enumerated (`enum`) data type.

When you define a partial IC structure:

- Include only fields that are in the bus.
- You can omit fields that are in the bus.
- Make the field in the IC structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, you can specify the structure fields in a different order than the order of the elements in the bus.

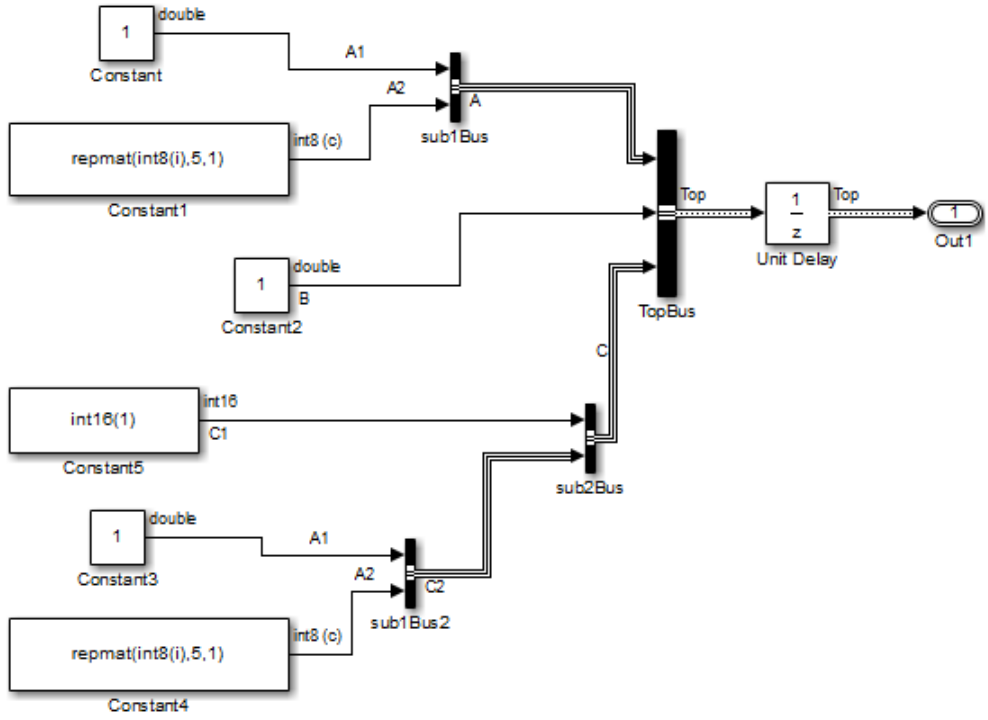
Note: The value of an IC structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking during an update diagram and when you run the model.

Examples of Partial Structures

Suppose you have a bus, `Top`, composed of three elements: `A`, `B`, and `C`, with these characteristics:

- `A` is a nested bus, with two signal elements.
- `B` is a single signal.
- `C` is a nested bus that includes bus `A` as a nested bus.

The following model, `ex_busic` includes the nested `Top` bus. The screen capture below shows the model after it has been updated. .



The following diagram summarizes the `Top` bus hierarchy and the data type, dimension, and complexity of the bus elements .

```
Top
   A (sub1)
      A1 (double)
      A2 (int8, 5x1, complex)
   B (double)
   C (sub2)
      C1 (int16)
      C2 (sub1)
         A1 (double)
         A2 (int8, 5x1, complex)
```

Valid partial IC structures

In the following examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model.

The following table shows valid initial condition specifications.

Valid Syntax	Description
`K.A.A1 = 3`	Initializes the bus element `Top.A.A1` using the value `3`.
`K = struct('C',struct('C1',int16(4)))`	The bus element `Top.C.C1` is `int16`. The corresponding structure field explicitly specifies `int16(4)`. Alternatively, you could specify the field value as `4` without specifying an explicit data type.
`K = struct('B',3,'A',struct('A1',4))`	Bus element `Top.B` and `Top.A` are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.

Invalid partial IC structures

In the following examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model.

These three initial condition specifications are *not* valid:

Invalid Syntax	Reason the Syntax Is Invalid
`K.A.A2 = 3`	Value dimension and complexity do not match. The bus element `Top.A.A2` is `5x1`, but `K.A.A2` is `1x1`; `Top.A.A2` is complex, but `K.A.A2` is real.
`K.C.C2 = 3`	You cannot use a scalar value to initialize IC substructures.
`K = struct('B',3,'X',4)`	You cannot specify fields that are not in the bus (`X` does not exist in the bus).

Creating Full IC Structures Using Simulink.Bus.createMATLABStruct

Use the `Simulink.Bus.createMATLABStruct` function to streamline the process of creating a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus signal. This function fills all the elements that you do not specify with the ground values for those elements.

You can use several different kinds of input with the `Simulink.Bus.createMATLABStruct` function, including

- A bus object name
- An array of port handles

You can invoke the `Simulink.Bus.createMATLABStruct` function from the Bus Editor. Select the bus object for which you want to create a full MATLAB structure, and then use one of these approaches:

- Select the **File > Create a MATLAB structure** menu item.
- Click the **Create a MATLAB structure** icon ( ) from the toolbar.

You can then edit the MATLAB structure in the MATLAB Editor.

See the `Simulink.Bus.createMATLABStruct` documentation for details.

Check for Partial Structures with Model Advisor

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus signal, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink "Check structure parameter usage with bus signals"** check. This check identifies partial IC structures.

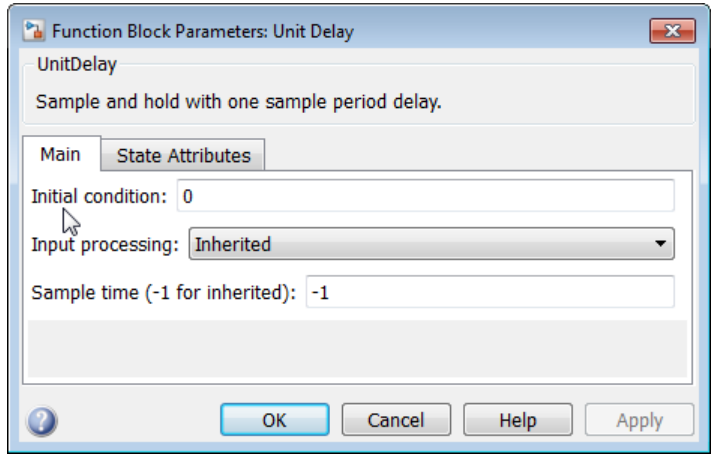
Control Data Types of Structure Fields

If any of the signal elements of the target bus use a data type other than `double`, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See "Control Data Types of Initial Condition Structure Fields" on page 63-137.

Three Ways to Initialize Bus Signals Using Block Parameters

Initialize a bus signal by setting the initial condition parameter for a block that receives a bus signal as input and that supports bus initialization (see "Blocks that Support Bus Signal Initialization" on page 63-78).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.



For a block that supports bus signal initialization, you can replace the default value of `0` using one of these approaches:

- "MATLAB Structure for Initialization" on page 63-85
- "MATLAB Variable for Initialization" on page 63-86
- "Simulink.Parameter for Initialization" on page 63-87

All three approaches require that you define an IC structure (see "Create Initial Condition (IC) Structures" on page 63-79). You cannot specify a nonzero scalar value or any other type of value other than `0`, an IC structure, or `Simulink.Parameter` object to initialize a bus signal.

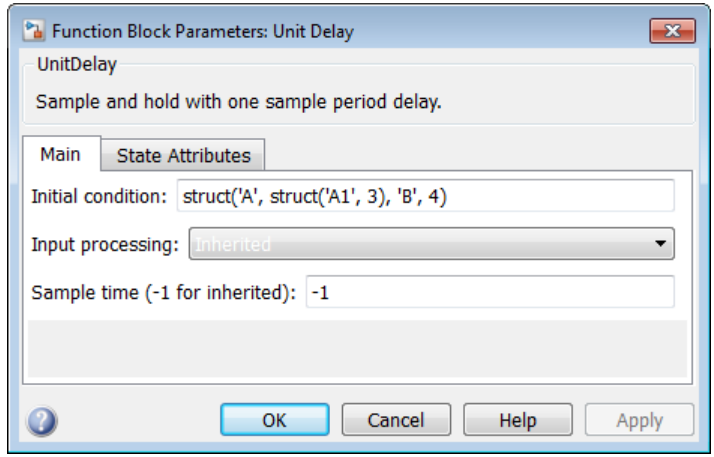
Defining an IC structure as a MATLAB variable, rather than specifying the IC structure directly in the block parameters dialog box offers several advantages, including:

- Reuse of the IC structure for multiple blocks
- Using the IC structure as a tunable parameter in the generated code

MATLAB Structure for Initialization

You can initialize a bus signal using a MATLAB structure that explicitly defines the initial conditions for the bus signal.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure such as shown below:



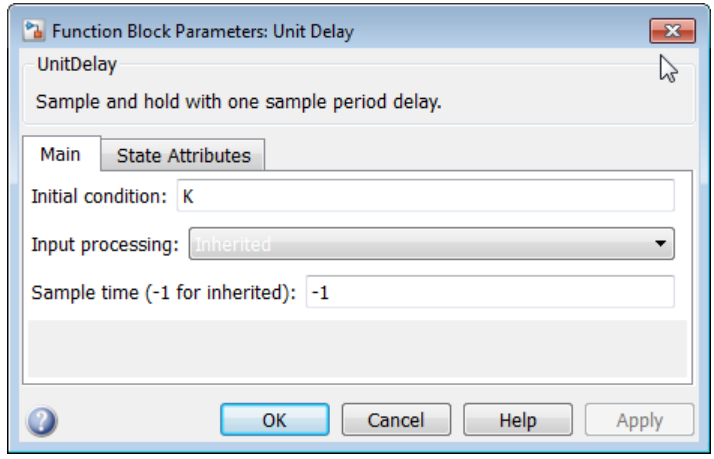
MATLAB Variable for Initialization

You can initialize a bus signal using a MATLAB variable that you define as an IC structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:



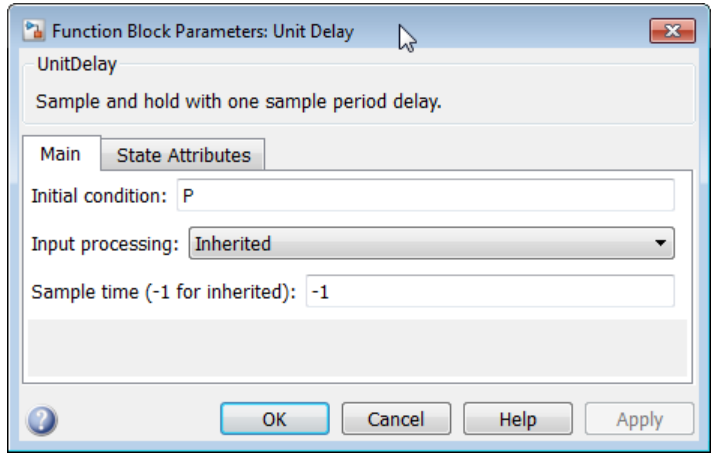
Simulink.Parameter for Initialization

You can initialize a bus signal using a `Simulink.Parameter` object that uses an IC structure for the `Value` property.

For example, you could define the partial structure `P` in the base workspace (reflecting the `ex_busic` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the `P` structure as the **Initial conditions** parameter of the Unit Delay block:

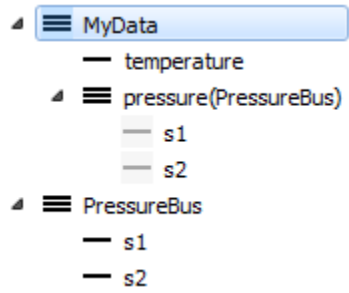


Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

Initialize an Array of Buses

Suppose that you define the bus types MyData and PressureBus.



Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.

```
initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;

initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;

initValues(3).temperature = int16(35);
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as `Unit Delay`.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all of the buses in the array.

```
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

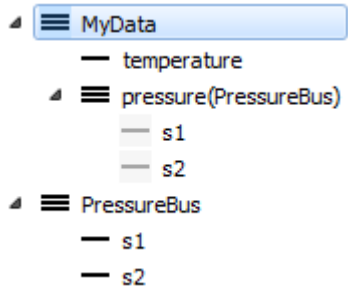
If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, `15`, for the signal element `temperature`. Similarly, the buses use the initial value `10.32` for the element `pressure.s1` and the value `9.46` for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

Initialize Nested Arrays of Buses

Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

1. In the Bus Editor, create the bus objects MyData and PressureBus.



2. In the hierarchy pane, select the bus element `pressure`. Set the **Dimensions** property to `[1 3]`.
3. Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all of the individual signals to the ground value, `0`.

   ```
   initStruct=Simulink.Bus.createMATLABStruct('MyData',[],[1 4]);
   ```
4. In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

   The four structures in the array each have the fields `temperature` and `pressure`.
5. Double-click one of the `pressure` fields to inspect it.

   The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.
6. To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

   Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```
initStruct(3).pressure(2).s1 = 15.35;
```

Setting Diagnostics to Support Bus Signal Initialization

To enable bus signal initialization, before you start a simulation, set the following two Configuration Parameter diagnostics as indicated:

- In the **Configuration Parameters** > **Diagnostics** > **Connectivity** pane, set **"Mux blocks used to create bus signals"** to `error`.
- On the **Configuration Parameters** > **All Parameters** tab, set **"Underspecified initialization detection"** to `simplified`.

The documentation for these diagnostics explains how convert your model to handle error messages the diagnostics generate.

Combine Buses into an Array of Buses

In this section...
"What Is an Array of Buses?" on page 63-91
"Benefits of an Array of Buses" on page 63-92
"Array of Buses Limitations" on page 63-93
"Define an Array of Buses" on page 63-95

Tip Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see "Techniques for Combining Signals" on page 63-3.

What Is an Array of Buses?

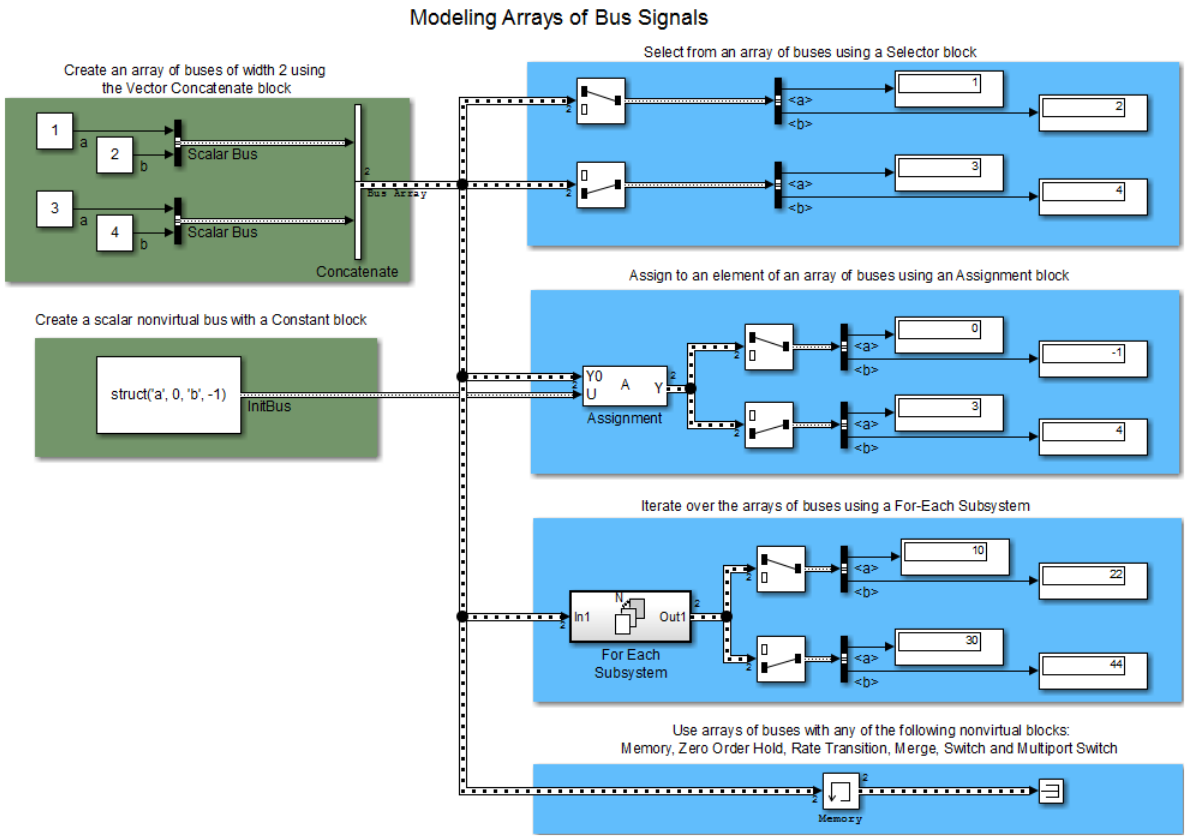
An array of buses is an array whose elements are buses. Each element in an array of buses must be nonvirtual and must have the same bus type. Each bus object has the same signal name, hierarchy, and attributes for its bus elements.

An example of using an array of buses is to model a multi-channel communication system. You can model all of the channels using the same bus object, although each of the channels could have a different value.

Using arrays of buses involves:

- Using a bus object as a data type (see "Specify a Bus Object Data Type" on page 57-50)
- Specifying dimensions for the bus and bus elements

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. When you update the diagram, the model looks like the following figure:



The model uses the array of buses with:

- An Assignment block, to assign a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

Benefits of an Array of Buses

Using an array of buses:

- Represents structured data compactly

    - Reduces model complexity
    - Reduces maintenance by centralizing algorithms used for processing multiple buses
- Streamlines iterative processing of multiple buses of the same type, for example, by using a For Each Subsystem with the array of buses
- Simplifies changing the number of buses, without your having to restructure the rest of the model or make updates in multiple places in the model
- Allows models to use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type, rather than your creating custom S-functions to manage packing and unpacking structure signals
- Supports using the combined bus data across subsystem boundaries, model reference boundaries, and into or out of a MATLAB Function block
- Allows you to keep all the logic in the Simulink model, rather than splitting the logic between C code and the Simulink model
    - Supports integrated consistency and correctness checking, maintaining metadata in the model, and avoids your keeping track of model components in two different environments
- Generates code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures
    - Simplifies indexing into an array for Simulink computations, using a `for` loop on indexed structures

Array of Buses Limitations

Bus Limitations

The buses combined into an array must all:

- Be nonvirtual
- Have the same bus type (that is, same name, hierarchies, and attributes for the bus elements)
- Have no variable-size signals or frame-based signals

Supported Blocks

You can use arrays of buses with the following blocks:

- Virtual blocks
- Several nonvirtual blocks, such as:
  - Some signal routing blocks (for example, Data Store Memory, Merge, and Switch)
  - Rate Transition and Zero-Order Hold blocks
- Several additional blocks, such as Assignment, MATLAB Function, and Signal Conversion

For a complete list, see "Blocks That Support Arrays of Buses" on page 63-97. That section describes requirements for using the supported blocks.

Structure Parameter Limitations

To initialize an array of buses with structure parameters, you can use:

- The number `0`. In this case, all of the individual signals in the array of buses use the initial value `0`.
- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

You cannot use partial structures.

If you use an array of structures, all of the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

For more information about specifying initial conditions for bus signals, see "Specify Initial Conditions for Bus Signals" on page 63-78.

Signal Logging Limitation

Simulink does not log signals inside referenced models in Rapid Accelerator mode.

Stateflow Limitations

Stateflow action language does not support arrays of buses.

Define an Array of Buses

For information about the kinds of buses that you can combine into an array of buses, see "Bus Limitations" on page 63-93.

To define an array of buses, use a `Concatenate` block. The table describes the array of buses input requirements and output for each of the Vector Concatenate and the Matrix Concatenate versions of the Concatenate block.

Block	Bus Signal Input Requirement	Output
Vector Concatenate	Vectors, row vectors, or columns vectors	If any of the inputs are row or column vectors, output is a row or column vector.
Matrix Concatenate	Signals of any dimensionality (scalars, vectors, and matrices)	Trailing dimensions are assumed to be 1 for lower dimensionality inputs. Concatenation is on the dimension that you specify with the **Concatenate dimension** parameter.

Note: Do not use a Mux block or a Bus Creator block to define an array of buses. Instead, use a Bus Creator block to create scalar bus signals.

1. Define *one* bus object to use for *all* of the buses that you want to combine into an array of buses. For information about defining bus objects, see "Create Bus Objects" on page 63-37.

   The `sldemo_bus_arrays` model defines an `sldemo_bus_arrays_busobject` bus object, which both of the Bus Creator blocks use for the input bus signals (`Scalar Bus`) for the array of buses.

2. Add a `Vector Concatenate` or `Matrix Concatenate` block to the model and open the block's parameters dialog box.

The `sldemo_bus_arrays_busobject` model uses a Vector Concatenate block, because the inputs are scalars.

3. Set the **Number of inputs** parameter to be the number of buses that you want to be in the array of buses.

   The block icon displays the number of input ports that you specify.

4. Set the **Mode** parameter to match the type of the input bus data.

   In the `sldemo_bus_arrays` model, the input bus data is scalar, so the **Mode** setting is `Vector`.

5. If you use a Matrix Concatenation block, set the **Concatenate dimension** parameter to specify the output dimension along which to concatenate the input arrays. Enter one of the following values:

   - `1` — concatenate input arrays vertically
   - `2` — concatenate input arrays horizontally
   - A higher dimension than 2 — perform multidimensional concatenation on the inputs

6. Connect to the Concatenate block all of the buses that you want to be in the array of buses.

Blocks That Support Arrays of Buses

The following blocks support arrays of buses:

- Virtual blocks (see "Nonvirtual and Virtual Blocks" on page 33-2)
- These nonvirtual blocks:
  - `Data Store Memory`
  - `Data Store Read`
  - `Data Store Write`
  - `Memory`
  - `Merge`
  - `Multiport Switch`
  - `Rate Transition`
  - `Switch`
  - `Unit Delay`
  - `Zero-Order Hold`
- `Assignment`
- `MATLAB Function`
- `Matrix Concatenate`
- `Selector`
- `Signal Conversion`
- `Vector Concatenate`
- `Width`

- `Two-Way Connection` (a Simscape block)

Block Parameter Settings

The following table describes the block parameter settings for blocks that support arrays of buses. This information is also in the reference pages for each of these blocks.

For usage information for bus-related blocks, see "Arrays of Buses with Bus-Related Blocks" on page 63-99.

Block	Block Parameters Settings
`Memory`	**Initial condition** — You can specify this parameter with: • The value `0`. In this case, all of the individual signals in the array of buses use the initial value `0`. • An array of structures that specifies an initial condition for each of the individual signals in the array of buses. • A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

`Merge`	• **Allow unequal port widths** — Clear this parameter.
	• **Number of inputs** — Set to a value of 2 or greater.
	• **Initial condition** — You can specify this parameter with:
	  • The value `0`. In this case, all of the individual signals in the array of buses use the initial value `0`.
	  • An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
	  • A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the bus signals in the array.

Block	Block Parameters Settings
`Multiport Switch`	**Number of data ports** — Set to a value of 2 or greater.
`Signal Conversion`	**Output** — Set to `Signal copy`.
`Switch`	**Threshold** — Specify a scalar threshold.

Arrays of Buses with Bus-Related Blocks

To select a signal within an array of buses:

1. Use a Selector block to find the appropriate bus within the array of buses.
2. Use a Bus Selector block to select the signal.

To assign a value to a signal within an array of buses:

1. Use a Bus Assignment block to assign a value to a bus element.
2. Use the Assignment block to assign the bus to the array of buses.

Bus Selector and Bus Assignment blocks can only accept scalar buses, not arrays of buses.

A `Bus Creator` block can accept an array of buses as input, but cannot have an array of buses as output.

For details, see "Set Up a Model to Use Arrays of Buses" on page 63-99.

Set Up a Model to Use Arrays of Buses

Setting up a model to use an array of buses usually involves basic tasks similar to these:

1. Define the array of buses (see "Define an Array of Buses" on page 63-95).
2. Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a For Each Subsystem block or an Iterator block.

   ### Perform Iterative Processing

   You can perform iterative processing on the bus signal data of an array of buses using blocks such as a `For Each Subsystem` block, a `While Iterator`

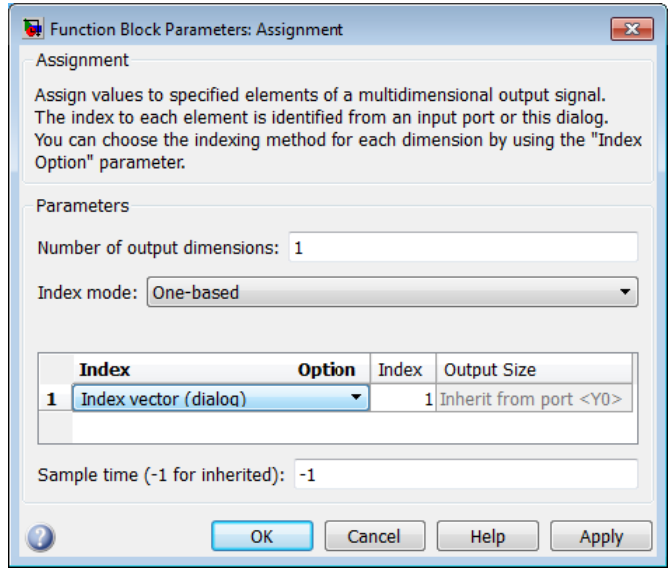
`Subsystem` block, or a `For Iterator Subsystem` block. You can use one of these blocks to perform the same kind of processing on each bus in the array of buses, or on a selected subset of buses in the array of buses.

3. Connect the array of buses signal from the Concatenate block to the iterative processing subsystem.
4. Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).
   a. Operate on the array of buses (using Selector and Assignment blocks).
   b. Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a scalar bus within the subsystem.

Assign values into an array of buses

Use an `Assignment` block to assign values to specified elements in a bus array.

For example, in the `sldemo_bus_arrays` model, the Assignment block assigns the value to the first element of the array of buses.

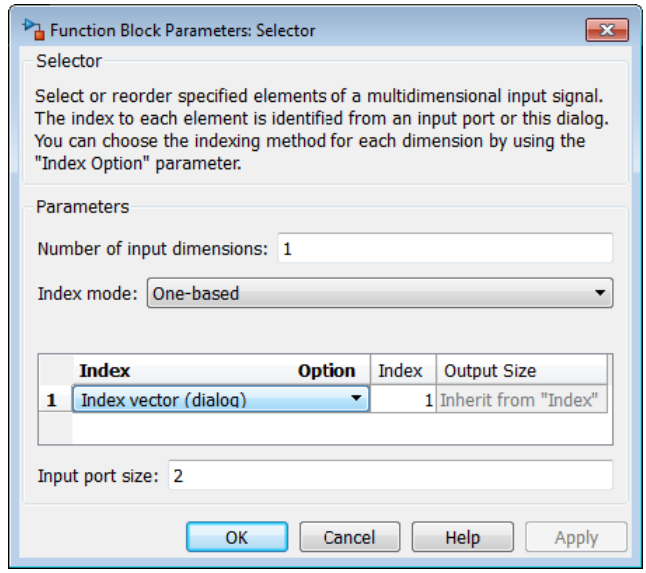


To assign bus elements within a bus signal, use the `Bus Assignment` block. The input for the Bus Assignment block must be a scalar bus signal.

Select bus elements from an array of buses

Use a `Selector` block to select elements of an array of buses. The input array of buses can have any dimension. The output bus signal of the Selector block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses Selector blocks to select elements from the array of buses signal that the Assignment and For Each Subsystem blocks outputs. In this example, the block parameters dialog box for the Selector block that selects the first element looks like this:



To select bus elements within a bus signal, use the `Bus Selector` block. The input for the Bus Selector block must be a scalar bus signal.

5 Optionally, import or log array of buses data.

Import array of buses data

Use a root Inport block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 59-152.

You cannot use a From Workspace or From File block to import data for an array of buses.

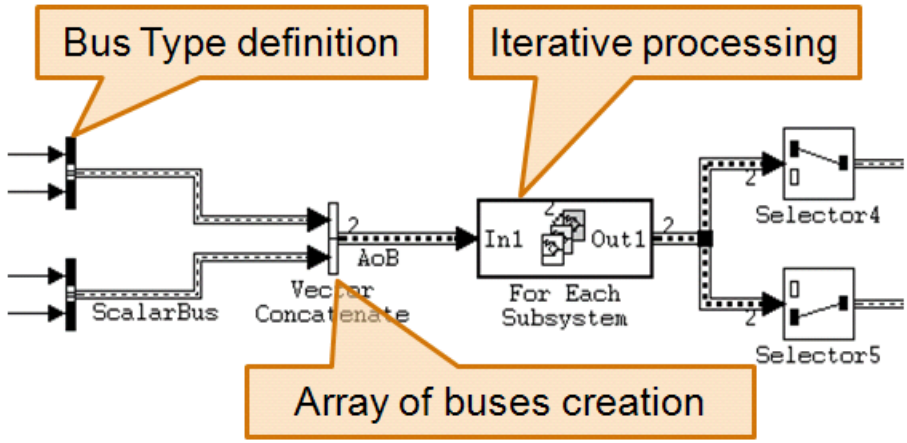
Log Array of Buses Signals

To export an array of buses signal, you must log the signal, using the Signal Properties dialog box. For more information, see “Save Runtime Data from Simulation”.

Note: Simulink does not log signals inside referenced models in Rapid Accelerator mode.

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 59-30.

The resulting model includes these components.



Set Diagnostic

Before you run a simulation on a model that uses an array of buses, in the **Configuration Parameters > Diagnostics > Connectivity** pane, check that the **Mux blocks used to create bus signals** parameter uses the default setting of `error`.

Signal Line Style

After you create an array of buses and update the diagram, the line style for the array of buses signal is a thicker version of the signal line style for a nonvirtual bus signal.

For example, in the `sldemo_bus_arrays` model, the `Scalar Bus` signal is a nonvirtual bus signal, and the `Bus Array` output signal of the Concatenate block is an array of buses signal.

Convert Models to Use Arrays of Buses

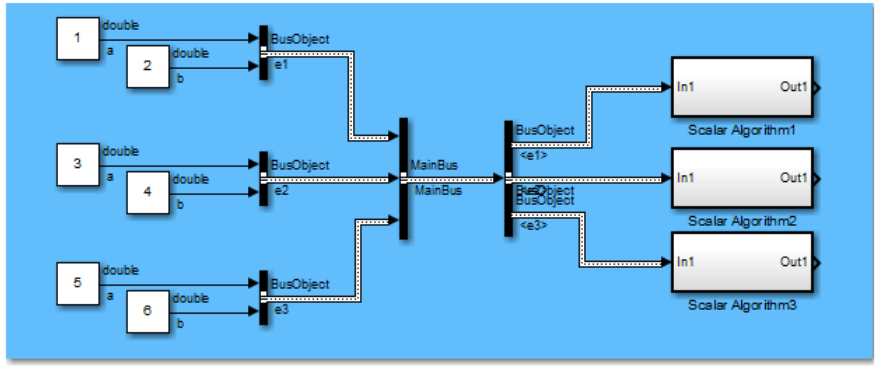
There are several reasons to convert a model to use an array of buses (see “Benefits of an Array of Buses” on page 63-92). For example:

- The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
- The model that has grown in complexity.

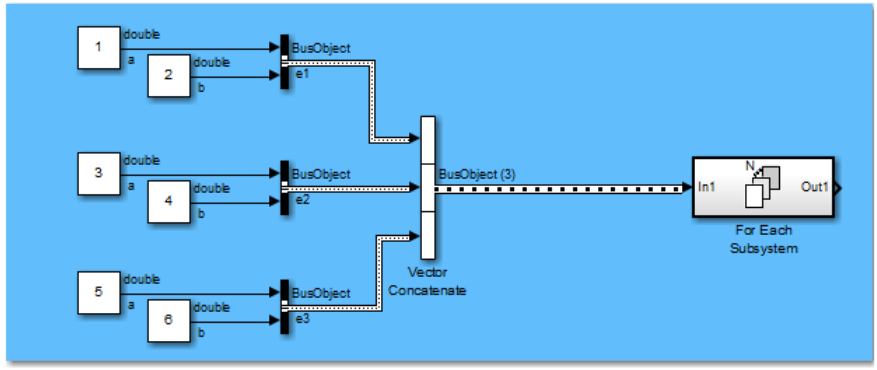
General Conversion Approach

This section presents a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For details about these techniques, see “Combine Buses into an Array of Buses” on page 63-91 and “Arrays of Buses in Models” on page 63-97.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.



Original modeling pattern



New modeling pattern

In the original modeling pattern:

- The target bus signal to be converted is named `MainBus`, and it has three elements, each of type `BusObject`.
- The `ScalarAlgorithm1`, `ScalarAlgorithm2`, and `ScalarAlgorithm3` subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.
- A Bus Selector block picks out each element of `MainBus` to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:

- A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
- Adding another element to `MainBus` involves changing the bus object definition and the Bus Selector block, and adding a new subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

1. Identify the target bus and associated algorithm that you want to convert. Typically, the target bus signal is a bus of buses, where each element bus signal is of the same type.

   - The bus that you convert must be a nonvirtual bus. You can convert a virtual bus to a nonvirtual bus if all elements of the target bus have the same sample time (or if the sample time is inherited).
   - The target bus cannot have variable-dimensioned and frame-based elements.

2. Use a Concatenate block to convert the original bus of buses signal to an array of buses.

   In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus signal is `BusObject`. The new model eliminates the wrapper bus signal (`MainBus`).

3. Replace all identical copies of the algorithm subsystem with a single For-Each subsystem that encapsulates the scalar algorithm. Connect the array of buses signal to the For-Each subsystem.

   The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

4. Configure the For Each Subsystem block to iterate over the input array of buses signal and concatenate the output bus signal.

   The scalar algorithm within the For-Each subsystem cannot have continuous states. For additional limitations, see the `For Each Subsystem` block documentation.

Repeat an Algorithm Using a `For Each Subsystem`

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. At the same time, many variables can crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This example shows how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

In this section...

"Explore Example Model" on page 63-108

"Reduce Signal Line Density with Buses" on page 63-109

"Repeat Algorithm Using For Each Subsystem Blocks and Arrays of Buses" on page 63-112

"Organize Parameters into Arrays of Structures" on page 63-115

"Inspect the Converted Model" on page 63-117

Explore Example Model

1. Open the example model ex_repeat_algorithm. The model creates about 30 variables in the base workspace.
2. Inspect the subsystem Burner_1_Analysis. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as `Constant` and `Discrete-Time Integrator`.
3. Inspect the subsystems Burner_2_Analysis and Burner_3_Analysis. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
4. Inspect the three Analysis_Delay subsystems. These subsystems repeat a different algorithm from the one in the Analysis subsystems.
5. Return to the top level of the model. The `Memory` blocks delay the input signals before they enter the Analysis_Delay subsystems.

6 Look at the **Data Import/Export** pane of the Configuration Parameters dialog box. The model uses the variables `SensorsInput` and `t` as simulation inputs.

   During simulation, each of the nine columns in the matrix variable `SensorsInput` provides input data for an `Inport` block at the top level of the model.

Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.

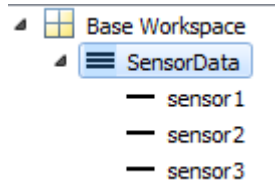
Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all of the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with `For Each Subsystem` blocks.

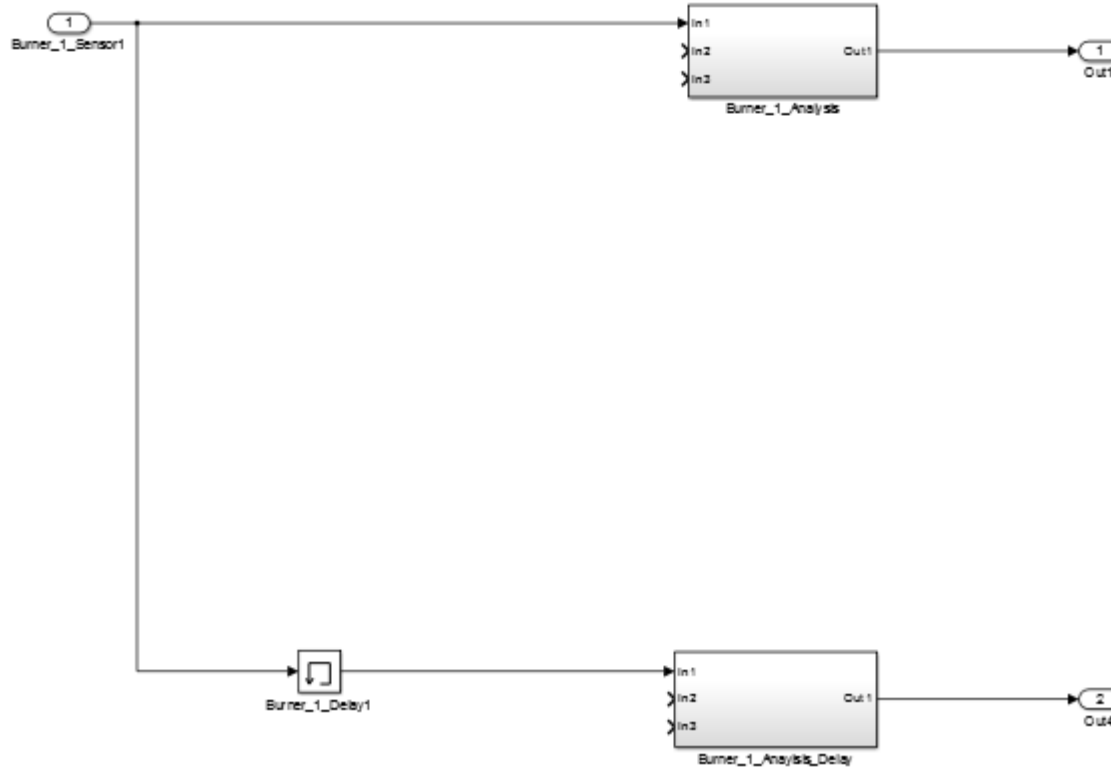
1 Open the Bus Editor.

```
buseditor
```

2 Create a bus type `SensorData` with three signal elements: `sensor1`, `sensor2`, and `sensor3`.



3 Delete the blocks as shown in the figure, leaving only the Burner_1_Sensor1 and Burner_1_Delay1 blocks as inputs to the two remaining subsystems.



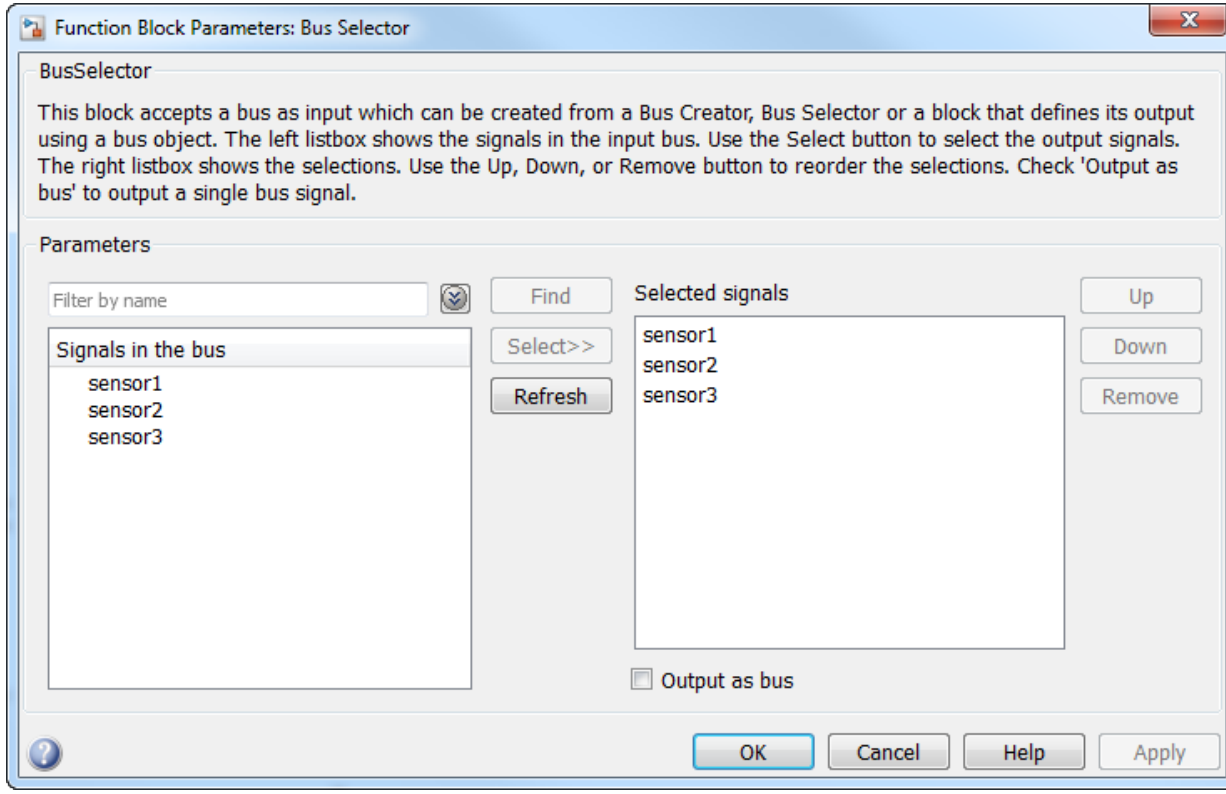
4 On the **Signal Attributes** tab of the Burner_1_Sensor1 `Inport` block dialog box, set **Data type** to `Bus: SensorData`.

   The output of the block is a bus signal that contains the three signal elements `sensor1`, `sensor2`, and `sensor3`.

5 Open the subsystem Burner_1_Analysis. Delete the signal output lines of the three `Inport` blocks. Delete the In2 and In3 `Inport` blocks.

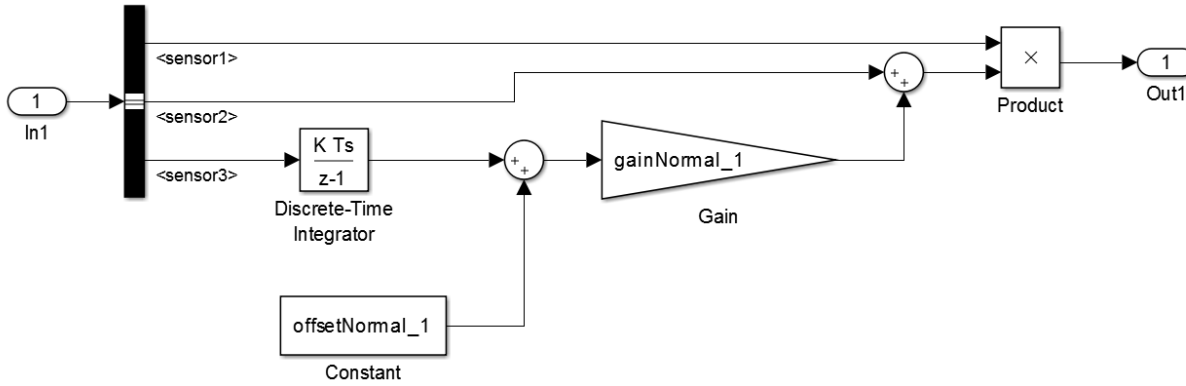
6 Add a `Bus Selector` block to the right of the In1 `Inport` block. Connect the `Inport` block output to the `Bus Selector` block.

7 In the `Bus Selector` block dialog box, select the signals `sensor1`, `sensor2`, and `sensor3`.



The `Bus Selector` block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

8 In the subsystem, connect the blocks as shown.



9 In the subsystem Burner_1_Analysis_Delay, use a `Bus Selector` block to extract the signals in the bus. Use the same technique as you did in the subsystem Burner_1_Analysis.

Repeat Algorithm Using `For Each Subsystem` Blocks and Arrays of Buses

A `For Each Subsystem` block partitions an input signal, and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use `For Each subsystem`s to repeat an algorithm in an iterative fashion. This approach improves model readability and allows you to easily change the repeated algorithm.

1 Add two `For Each Subsystem` blocks to the model. Name one of the subsystems Burner_Analysis. Name the other subsystem Burner_Analysis_Delay.

2 Copy the contents of the subsystem Burner_1_Analysis into the subsystem Burner_Analysis. Before you paste the blocks, delete the `Inport` and `Outport` blocks in the `For Each subsystem`.

3 In the `For Each` block dialog box in the Burner_Analysis subsystem, select the check box to partition the input `In1`.

4. Copy the contents of the subsystem Burner_1_Analysis_Delay into the subsystem Burner_Analysis_Delay.
5. In the `For Each` block dialog box in the Burner_Analysis_Delay subsystem, select the check box to partition the input `In1`.
6. At the top level of the model, delete the subsystems Burner_1_Analysis and Burner_1_Analysis_Delay. Connect the new `For Each Subsystem` blocks in their place.
7. On the **Signal Attributes** tab of the Burner_1_Sensor1 `Inport` block dialog box, set **Port dimensions** to `3`.

   The block output is a three-element array of buses. The `For Each subsystem`s in the model repeat an algorithm for each of the three buses in the array.
8. Create a Simulink.SimulationData.Dataset object that the `Inport` block can use to import the simulation data. You can use this code to create the object and store it in the variable `SensorsInput`.

```
% First, create an array of structures whose field values are
% timeseries objects.

for i = 1:3 % Burner number

    % Sensor 1
    eval(['tempInput(1,' num2str(i) ').sensor1 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+1) '));'])

    % Sensor 2
    eval(['tempInput(1,' num2str(i) ').sensor2 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+2) '));'])

    % Sensor 3
    eval(['tempInput(1,' num2str(i) ').sensor3 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+3) '));'])

end

% Create the Dataset object.

SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput,tempInput,'element1');

clear tempInput t i
```

The code first creates a variable `tempInput` that contains an array of three structures. Each structure has three fields that correspond to the signal elements in the bus type `SensorData`, and each field stores a MATLAB `timeseries` object. Each `timeseries` object stores one of the nine columns of data from the variable `SensorsInput`, which stored the simulation input data for each of the sensors.

The code then overwrites `SensorsInput` with a new `Simulink.SimulationData.Dataset` object, and adds `tempInput` as an element of the object.

9 On the **Data Import/Export** pane of the Configuration Parameters dialog box, set **Input** to `SensorsInput`.

Since `SensorsInput` provides simulation input data in the form of `timeseries` objects, you do not need to specify a variable that contains time data.

10 Create an array of structures to initialize the remaining `Memory` block, and store the array in the variable `initForDelay`. Specify the structure fields with the values of the existing initialization variables such as `initDelay_1_sensor1`.

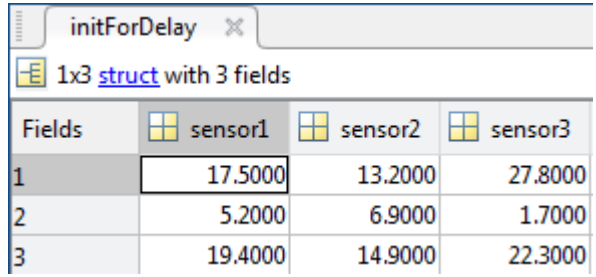
```
for i = 1:3 % Burner number

    % Sensor 1
    eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
        'initDelay_' num2str(i) '_sensor1;'])

    % Sensor 2
    eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
        'initDelay_' num2str(i) '_sensor2;'])

    % Sensor 3
    eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
        'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable `initForDelay`, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: `sensor1`, `sensor2`, and `sensor3`.



11 In the `Memory` block dialog box, set **Initial condition** to `initForDelay`.

The `Memory` block output is an array of buses that requires initialization. Each signal element in the array of buses acquires an initial value from the corresponding field in the array of structures.

Organize Parameters into Arrays of Structures

The base workspace contains many variables that the example model uses for block parameters. To reduce the number of workspace variables, package them into arrays of structures, and use the individual structure fields to specify block parameters.

A `For Each Subsystem` block can partition an array of values that you specify as a mask parameter. Each iteration of the subsystem uses a single partition of the array to specify block parameters. If you specify the parameter as an array of structures, each iteration of the subsystem can use one of the structures in the array.

1 Create an array of structures to parameterize the Burner_Analysis `For Each subsystem`, and store the array in the variable `paramsNormal`. Specify the structure fields by using the values of existing parameter variables such as `gainNormal_1`, `offsetNormal_1`, and `initDelayed_1`.

```
for i = 1:3
    eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';'])
    eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';'])
    eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';'])
end
```

The variable contains an array of three structures that each has three fields: `gain`, `offset`, and `init`.

2. In the model, right-click the Burner_Analysis `For Each subsystem` and select **Mask** > **Create Mask**.
3. On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
4. In the mask for the Burner_Analysis subsystem, set **Parameter structure** to `paramsNormal`.
5. Open the subsystem. In the `For Each` block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to `2`.
6. For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
`Gain`	**Gain**	`paramStruct.gain`
`Discrete-Time Integrator`	**Initial condition**	`paramStruct.init`
`Constant`	**Constant value**	`paramStruct.offset`

7. Create an array of structures to parameterize the Burner_Analysis_Delay `For Each subsystem`, and store the array in the variable `paramsForDelay`.

```
for i = 1:3
    eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';'])
end
```

8. At the top level of the model, right-click the Burner_Analysis_Delay `For Each subsystem` and select **Mask** > **Create Mask**.
9. On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
10. In the mask for the `For Each Subsystem` block, set **Parameter structure** to `paramsForDelay`.
11. Open the subsystem. In the `For Each` block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to `2`.
12. For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
Gain	**Gain**	paramStruct.gain
Discrete-Time Integrator	**Initial condition**	paramStruct.init
Constant	**Constant value**	paramStruct.offset

13 Clear the unnecessary variables from the base workspace.

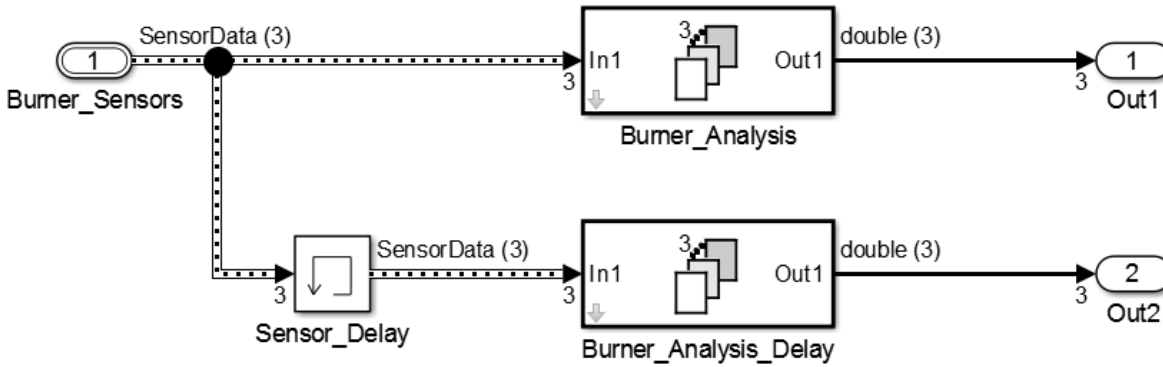
```
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```

The model requires very few variables in the base workspace.

Inspect the Converted Model

Update the diagram to view the new signal and subsystem organization.



The model input is an array of three bus signals. The model uses two For Each subsystems to execute the two algorithms on each of the three bus signals in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all of the old variables.

To view the completed model, open the example model ex_repeat_algorithm_complete.

Bus Data Crossing Model Reference Boundaries

A model reference boundary refers to the boundary between a model that contains a Model block and the referenced model. If you have bus data in a model that is passed to a Model block, then that data crosses the boundary to the referenced model.

To have bus data cross model reference boundaries:

1. Use a bus object (`Simulink.Bus`) to define the bus. For details, see "Create Bus Objects" on page 63-37 and "Associate Bus Objects with Simulink Blocks" on page 63-28.

   You can use a nonvirtual or a virtual bus as an input to a referenced model.
2. Decide whether to use a virtual or nonvirtual bus. Using a nonvirtual bus provides a well-defined data interface for code generation. See "Virtual and Nonvirtual Buses" on page 63-14.

Connect Multi-Rate Buses to Referenced Models

You can input a single-rate bus to a referenced model. To input the signals in a multi-rate bus to a referenced model, insert blocks into the parent and referenced model as follows:

1. **In the parent model:** Insert a `Rate Transition` block to convert the multi-rate bus to a single-rate bus. The Rate Transition block must specify a rate in its **Block Parameters > Output port sample time** field unless one of the following is true:
   - The **Configuration Parameters > Solver** pane specifies a rate with these settings:
     - **Periodic sample time constraint** is `Specified`.
     - **Sample time properties** contains the specified rate.
   - The `Inport` block that accepts the bus in the referenced model specifies a rate in its **Block Properties > Signal Attributes > Sample time** field.
2. **In the referenced model:** Use a `Bus Selector` block to pick out signals of interest, and use `Rate Transition` blocks to convert the signals to the desired rates.

Limitations for Virtual Buses

If you use a bus signal as an input to or an output from a referenced model:

- The bus cannot contain a variable-size signal element.

  As a workaround, use a nonvirtual bus instead.
- For code generation, you cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

  As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.
- For code generation, you cannot configure function prototype control for the referenced model.

  As a workaround, use a nonvirtual bus instead.

Use the Upgrade Advisor to fix models saved before R2016a that engage these limitations. See "Update Models Saved Before R2016a" on page 63-120.

Update Models Saved Before R2016a

The behavior of models that meet these criteria is different than it is in R2016a and later releases:

- The model was saved in a release earlier than R2016a.
- The model has referenced models with bus inputs and outputs configured to be treated as virtual buses.

Use the Upgrade Advisor **Check virtual bus across model reference boundaries** check to avoid errors that the behavior differences can trigger. Run the **Analyze model hierarchy and continue upgrade sequence** check on the top-level model and then down through the model reference hierarchy.

Buses and Libraries

When you define a library block, the block can input, process, and output buses just as an ordinary subsystem can.

You need to provide the appropriate input bus signal if:

- You have a bus routing block (Bus Creator, Bus Selector, or Bus Assignment) block that is in a library.
- That block depends on signals that are input to the library.

To change that block in a library, perform these steps. For details about modifying library links, see “Work with Library Links” on page 38-17.

1. Copy the library block that uses that block to a model that connects an input bus.
2. Disable the link to the library block in this model.
3. Edit the bus routing block within the context of the outside model.
4. Resolve the link to the library.
5. In the Link Tool, in **Push/Restore Mode**, select `Push` to place the edited content into the library.
6. Save the library.

Alternatively, to configure the library to supply an appropriate bus signal, use a bus object to lock in the data type at the interface of a library subsystem block .

Prevent Bus and Mux Mixtures

In this section...
"What Are Bus and Mux Signal Mixtures?" on page 63-123
"Why Avoid Mixing Bus and Mux Signals?" on page 63-124
"When to Configure a Model to Prevent Bus and Mux Mixtures?" on page 63-125
"Two Upgrade Procedures" on page 63-125

What Are Bus and Mux Signal Mixtures?

A Simulink mux signal is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. All of the signals in a mux signal must have the same data type and complexity. For more information, see "Mux Signals" on page 62-11.

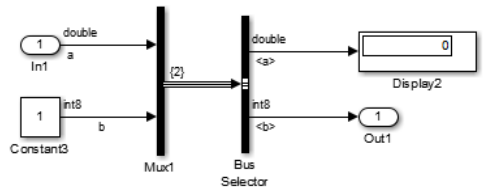
Bus signals can contain signals of different data types and complexities.

A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus, as described below.

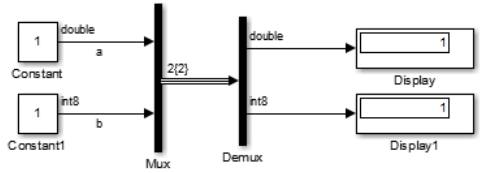
Mux Block That Creates a Virtual Bus

One way that a model can mix bus and mux signals is when a Mux block creates a virtual bus. For example:

- A signal from a Mux block connects to a Bus Selector block.



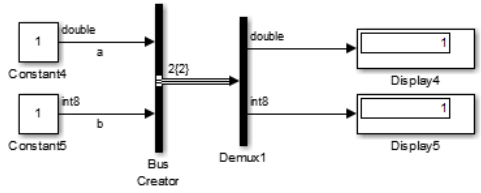
- Mux and Demux blocks combine a signal with different attributes (for example, data type or complexity).



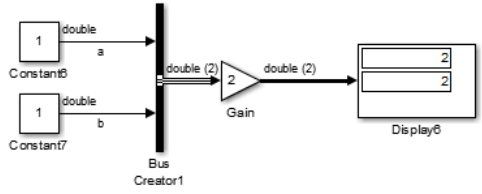
Bus Signal Treated as a Mux Signal

A second way that a model can mix bus and mux signals is when the model treats a bus signal as if it is a mux signal. For example:

- Bus Creator block that creates a signal to be used as a vector.



- Bus Creator block that creates a signal to be used as a vector.



Why Avoid Mixing Bus and Mux Signals?

Mixing bus and mux signals in a model causes your model to be less robust. Configuring your model to prevent bus and mux mixtures:

- Improves loop handling
- Produces clear error messages

- Contributes to consistent edit and compile time behavior

Configuring your model to prevent bus and mux mixtures not only makes your model more robust, it also allows you to update your model to take advantage of several features that you could not otherwise use, including:

- Nonzero initialization of bus signals
- Bus support for blocks such as Constant, Data Store Memory, From File, From Workspace, To File, and To Workspace
- Signal Hierarchy Viewer
- Signal label propagation enhancements
- Arrays of buses

When to Configure a Model to Prevent Bus and Mux Mixtures?

Configure a model to prevent bus and mux mixtures if *all* of the following conditions apply — the model:

- Was created before R2013b
- Contains one of the following: Bus Creator, Bus Selector, or Bus Assignment block, or a bus object
- Has **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** set to `none` or `warning`

Even if a model created before R2013b does not require that you configure it to prevent bus and mux mixtures, you may want to update it anyway. Doing so facilitates making future modifications to the model to use buses or features that require that the model is configured to prevent bus and mux mixtures.

Starting in R2013b, when you create a new model, Simulink automatically configures the model to avoid bus and mux mixtures. Simulink sets the **Mux blocks used to create bus signals** parameter to `error`. Then, when you do a model update or simulate the model, Simulink reports an error if you introduce a bus and mux mixture.

Two Upgrade Procedures

Configuring a model to prevent bus and mux mixtures involves performing these procedures:

- "Correct Mux Blocks That Create Bus Signals" on page 63-127
- "Correct Buses Used as Muxes" on page 63-132

The procedure to correct muxes that create bus signals not only configures your model to identify when you introduce a bus and mux mixture, it also automatically changes your model to correct many of the instances of such mixtures.

Correct Mux Blocks That Create Bus Signals

In this section...
"Choose the Appropriate Procedure" on page 63-127
"Models Without Model Referencing" on page 63-127
"Models With Model Referencing" on page 63-128
"Address Compatibility Issues After Running Upgrade Advisor" on page 63-129

Choose the Appropriate Procedure

The procedure that you perform depends on whether or not a model uses model referencing. Use the appropriate procedure, as described in:

- "Models Without Model Referencing" on page 63-127
- "Models With Model Referencing" on page 63-128

Models Without Model Referencing

1. Save a copy of the existing model and simulation results for the model.

   Because you might need to make several changes to your model during the conversion process, it can help to have the original model for reference and for comparing simulation results.
2. Open the Upgrade Advisor. In the Simulink Editor, select **Analysis > Model Advisor > Upgrade Advisor**.
3. Select **Check for Mux blocks used to create bus signals**.
4. Click **Run this check**.
5. Click **Modify**. The Upgrade Advisor replaces Mux blocks with Bus Creator blocks and sets the **Mux blocks used to create bus signals** configuration parameter to `error`.

   The Upgrade Advisor closes any models that it checks that contain library links.
6. If necessary, reopen the model. Rerun the check to confirm that the model passes.

   If the check fails, go to step 7.

7 Update your model to address the applicable modeling patterns described in "Address Compatibility Issues After Running Upgrade Advisor" on page 63-129 and rerun the check.

Models With Model Referencing

In a model that uses model referencing, the Upgrade Advisor upgrades the top model, but not the referenced model. To make the upgrade process more efficient for models that use model referencing, use *one* of the following approaches:

- For models that reference a small number of models (for example, five), in the Upgrade Advisor, run the **Analyze model hierarchy for upgrade issues** check. This check addresses bus and mux signal mixture issues for each referenced model.

  The steps for using the Upgrade Advisor are the same as described in "Models Without Model Referencing" on page 63-127.

- For models that have many referenced models (for example, more than five), use `find_mdlrefs` and `slreplace_mux` to find Mux blocks and replace them with Bus Creator blocks. You can create a script based on the following pattern.

```
[refMdls,~] = find_mdlrefs(mdl, true);

% run through reference models and top model
      for i = 1:length(refMdls)
         load_system(refMdls{i});

         % Add code if any model uses referenced configuration sets

         slreplace_mux(refMdls{i},false)  % reportonly = false;

         save_system(refMdls{i});
         close_system(refMdls{i});
      end
```

If a model does not compile, address the applicable modeling patterns described in "Address Compatibility Issues After Running Upgrade Advisor" on page 63-129 and rerun the **Analyze model hierarchy for upgrade issues** check or, for models with many referenced models, the script.

Address Compatibility Issues After Running Upgrade Advisor

For many models, running the Upgrade Advisor modifies your model so that Mux blocks no longer create bus signals. However, for some models you might encounter compatibility issues even after running the check. You need to modify your model manually to address those issues.

Also, after you compile the model using Upgrade Advisor, the Simulink Editor sometimes indicates that the model needs to be saved (that is, that the model is dirty), even though you did not make any changes. Save the model to prevent this issue from reoccurring for this model.

Modeling Pattern	Issue	Solution
Demux block with **Bus selection mode** enabled	You cannot use a Demux block to select bus signals.	Replace the Demux block with a Bus Selector block. If a Demux block has input from a Mux block, change the Mux block to a Bus Creator.
Data Store Memory block with **Data Type** set to `Inherit: auto`	A Data Store Memory block whose associated Data Store Read or Data Store Write blocks read or write bus signal data must use a bus object.	In the Data Store Memory block, set the **Data Type** signal attribute to `Bus: <BusObject>`.
Signal Conversion block **Output** parameter matches input bus type	A Signal Conversion block whose **Output** parameter is set to `Nonvirtual bus` requires a virtual bus input. A Signal Conversion block whose **Output** parameter is set to `Virtual bus` requires a nonvirtual bus input.	To create a copy of the input signal, set **Output** to `Signal copy`.
Merge, Switch, or Multiport Switch block with multiple bus inputs	Merge, Switch, and Multiport Switch blocks with multiple bus inputs require all of those inputs to have the same names and hierarchy.	Reconfigure the model so that the bus inputs all have the same names and hierarchy. To view the names and hierarchy of the bus signals,

Modeling Pattern	Issue	Solution
		use the "Signal Hierarchy Viewer" on page 63-8 .
Root Inport block outputting a virtual bus and specifying a value for **Port dimensions**	A root Inport block that outputs to a virtual bus must inherit the dimensions.	Set the Inport block **Port dimensions** signal attribute to `1` or `-1 (inherit)`.
Mux block with nonvirtual bus inputs	A Mux block cannot accept nonvirtual bus signals.	To treat the output as an array, replace the Mux block with a Vector Concatenate block. If you want a virtual bus output, use a Bus Creator block to combine the signals.
Bus to Vector block without a virtual bus signal input	A nonbus signal does not need a Bus to Vector block.	Remove the Bus to Vector block.
Assignment block with virtual bus inputs	The Upgrade Advisor converts the Assignment block `Y0` port bus input to a vector.	Add a Bus to Vector block before the Assignment block.
S-function using a nonvirtual bus	An S-function that is not a Level-2 C S-function does not support nonvirtual bus signals.	Change the S-function to be a Level-2 C S-function. Consider using an S-Function Builder block to create a Level-2 C S-function.
Stateflow chart with parameterized data type	In a Stateflow chart, you cannot parameterize the data type of an input or output in terms of another input or output if the data type is a bus object.	For the parameterized port, set **Data Type** to `Bus: <object name>`.
Subsystem with bus operations in a Stateflow chart	An Inport block inside a subsystem in a Stateflow chart requires a bus object data type if its signal is a bus.	In the Inport block, set **Data type** to `Bus: <object name>`.

Modeling Pattern	Issue	Solution
Ground block used as a bus source	The output signal of a Ground block cannot be a source for a bus.	Use a Constant block with **Constant value** set to 0 and the **Output data type** signal attribute set to `Bus: <object name>`.
Root Outport block with a single-element bus object data type	The input to the Outport block must be a bus if it specifies a bus object as its data type.	In the Outport block, set **Data type** to `Inherit: auto`.

Correct Buses Used as Muxes

In this section...
"Three Approaches" on page 63-132
"Use the Model Advisor" on page 63-132
"Explicitly Add Bus to Vector Blocks" on page 63-132
"Reorganize the Model" on page 63-134
"Bus to Vector Block Compatibility Issues" on page 63-135

Three Approaches

The three approaches that you can use to correct bus signals used as muxes are:

- "Use the Model Advisor" on page 63-132
- "Explicitly Add Bus to Vector Blocks" on page 63-132
- "Reorganize the Model" on page 63-134

Generally, using the Model Advisor is the most efficient approach.

Use the Model Advisor

Before you use the Model Advisor to correct bus signals used as a muxes, perform the steps described in "Correct Mux Blocks That Create Bus Signals" on page 63-127.

1. Open the Model Advisor from the Upgrade Advisor, or in the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
2. Select and run the **Simulink > Check bus usage** check.

   The Model Advisor reports any cases of bus signals treated as muxes.
3. Follow the Model Advisor suggestions to correct any errors reported by the check.

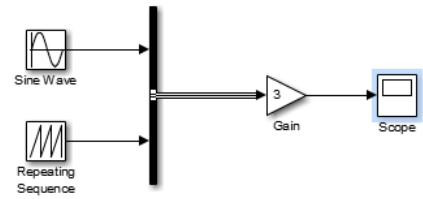
For additional information about using the Model Advisor, see "Consulting the Model Advisor" on page 5-2.

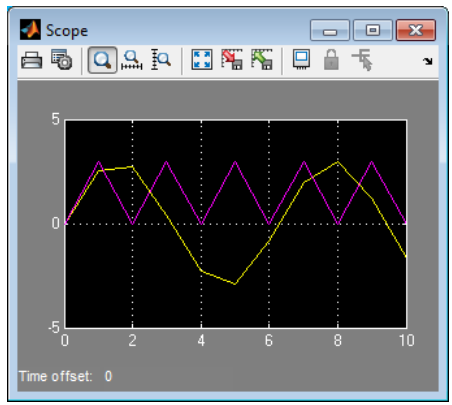
Explicitly Add Bus to Vector Blocks

You can explicitly add `Bus to Vector` blocks to convert the bus signal to a mux (vector), using one of these approaches:

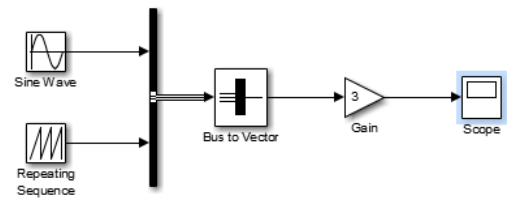
- Insert the Bus to Vector block into any bus used implicitly as a mux to explicitly convert the bus to a mux (vector).
- Use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

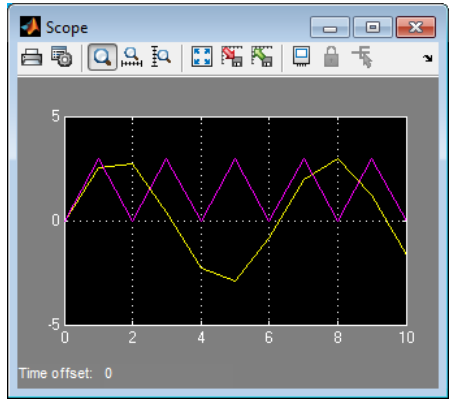
For example, this model uses a bus signal as a mux signal by using the bus as an input to a Gain block. The Scope block shows the simulation results.





This figure shows the same model, rebuilt after inserting a Bus to Vector block after the Bus Creator block.



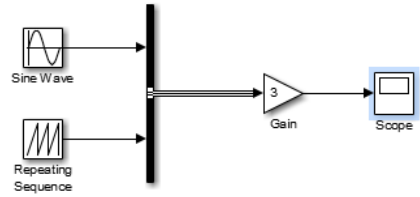


The results of simulation are the same in either case. The Bus to Vector block is virtual, and does not affect simulation results, code generation, or performance.

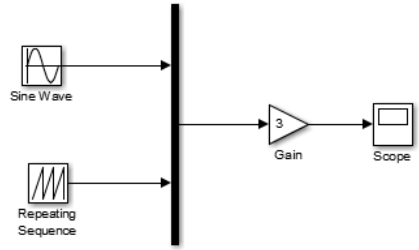
Reorganize the Model

You can replace blocks manually to avoid using bus signals as muxes. Change the sources for a block that require vector inputs to avoid feeding a bus signal into a block that requires vector input.

For example, in the following model, the Gain block requires a vector signal. However, the input signal is a bus signal created by a Bus Creator block.



Change the Bus Creator block to a Mux block to provide the required vector signal for the Gain block.



Challenges with reorganizing the model manually include:

- Identifying all of the occurrences in a model. (The Model Advisor check identifies all occurrences in the model and helps you to correct them.)
- Dealing with many occurrences in a model is time-consuming and error-prone.
- Reorganizing the model to address this issue can interfere with other aspects of the model.

Bus to Vector Block Compatibility Issues

If you use **Save As** to save a model in a version of the Simulink product before R2007a (V6.6), Simulink:

- Sets the `StrictBusMsg` parameter to `error` if its value is `WarnOnBusTreatedAsVector` or `ErrorOnBusTreatedAsVector`.
- Replaces each Bus to Vector block in the model with a null subsystem that outputs nothing.

The resulting model specifies strong type checking for Mux blocks used to create buses. Before you can use the model, you must reconnect or otherwise correct each signal that contained a Bus to Vector block but is now interrupted by a null subsystem.

Buses in the Generated Code

If you have Simulink Coder, the various techniques for defining buses are essentially equivalent for simulation, but the techniques can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, this is the generated code for the Bus Creator block in the `ex_bus_logging` model.

```
50
51      /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
52       *  BusCreator: '<Root>/LIMITBUSCreator'
53       *  Constant: '<Root>/lower_ saturation_ limit'
54       *  Constant: '<Root>/upper_saturation_limit'
55       */
56      ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
57      ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
58      ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
59
```

A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.

To group signals into structures in the generated code, use nonvirtual buses. See “Group Signals into Structures in the Generated Code Using Buses”.

Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See “Specify Initial Conditions for Bus Signals” on page 63-78.

If the signal elements of the target bus use numeric data types other than `double`, use the information in this table to decide how to control the data types of the fields in the initial condition structure. The technique that you choose can influence the efficiency and readability of the generated code.

Goal		Technique
In the generated code, inline the numeric	Avoid manually matching the field data types with those of the signal elements. Generate efficient code.	Use untyped expressions to set the field values. The field values do not require data types because

<table>
<tr><th colspan="4">Goal</th><th>Technique</th></tr>
<tr><td>values of the structure fields (nontunable) by setting Default parameter behavior to <code>Inlined</code>.</td><td colspan="3"></td><td>the structure is not tunable in the generated code.

However, if you later set Default parameter behavior to <code>Tunable</code>, the code can contain floating-point storage and inefficient explicit typecasts.</td></tr>
<tr><td rowspan="4">In the generated code, represent the initial condition structure as a tunable global structure by using either of these techniques:
• Set Default parameter behavior to <code>Tunable</code>.
• Apply a storage class to the initial condition structure by creating a <code>Simulink.Par</code> object.</td><td rowspan="4">Specify the structure directly in a block dialog box, or in a <code>Simulink.Signal</code> object, with an expression such as <code>struct('signal1',</code>
<code>2,7.2)</code> instead of storing the structure in a workspace variable. In this case, to generate a tunable structure in the code, you set Default parameter behavior to <code>Tunable</code>.</td><td colspan="2">Use a nonvirtual bus.</td><td>Use untyped expressions to set the field values.</td></tr>
<tr><td rowspan="2">Use a virtual bus.</td><td>Avoid manually matching the field data types with those of the signal elements.</td><td>Use untyped expressions to set the field values.</td></tr>
<tr><td>Generate more efficient code and avoid floating-point storage.</td><td>Match the structure field data types with the signal element types. Store the data type information in the <code>struct</code> by using typed expressions to set the field values.</td></tr>
</table>

Goal			Technique
	Store the structure in a workspace variable or `Simulink.Parameter` object. For example, use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to `Inlined`.	Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values. In the generated code, the structure fields use the data type `double`. The code algorithm uses explicit typecasts to reconcile the data type mismatches.
		Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a `Simulink.Bus` object to control the data types of the fields and the signal elements simultaneously. To use the Model Advisor to check your model for potentially expensive data type mismatches, see “Check structure parameter usage with bus signals”.
		Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the `Model` block.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a `Simulink.Bus` object to control the data types of the structure fields and the signal elements simultaneously. If you do not pass the structure to the referenced model as a model argument, use the information in the rest of this table to decide how to control the field data types.

For examples and more information about tunable initial conditions in the generated code, see "Control Signal and State Initialization in the Generated Code".

Use Untyped Expressions to Set Field Values

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus signal, the method that you use to apply the initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus signal `myBusSig` with these signal elements. Each element uses a specific data type.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See "Use Simulink.Bus.createMATLABStruct to Create Structure" on page 63-142.

Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

Use Typed Expressions to Set Field Values

Suppose that you create a bus signal `myBusSig` with this hierarchy of signal elements. Each element uses a specific data type.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```
initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.

To match a fixed-point data type, set the field value by using an `fi` object.

Change Field Value by Preserving Data Type Information

When you change the value of a field in an existing initial condition structure, you can use subscripted assignment, with the syntax `(:)`, to preserve the data type information in the field.

```
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

Use `Simulink.Bus.createMATLABStruct` to Create Structure

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically `0`. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.

Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a `Simulink.Bus` object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to manually match the field data types when you change the data types of the signal elements. To control the data types of the fields and the signal elements, use the `DataType` property of the elements in the bus object.

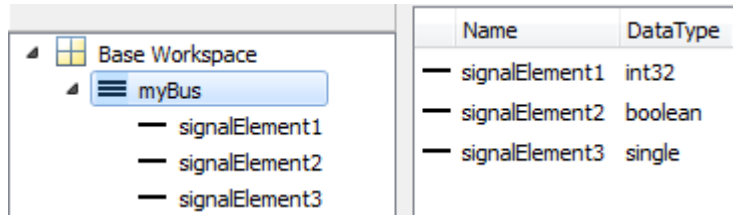
Suppose that you use a `Bus Creator` block to create a bus signal `myBusSig` with these signal elements.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

1 Open the Bus Editor.

```
buseditor
```

2 Create a bus object, myBus, that corresponds to the bus signal.



3 Create an initial condition structure `initStruct`. Used untyped expressions to set the field values. To enhance readability of the field `signalElement2`, use the Boolean value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

4 Create a `Simulink.Parameter` object to represent the structure.

```
initStruct = Simulink.Parameter(initStruct);
```

5 Use the parameter object to specify an initial condition for the bus signal. For example, in a `Unit Delay` block dialog box, set **Initial condition** to `initStruct`.

6 Use the bus object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

7 Use the bus object to specify the data type of the bus signal. For example, in the `Bus Creator` block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the bus object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the bus object.

For basic information about bus objects, see “Bus Objects” on page 63-27.

Configure Data Types for Existing Structure

To remove data type information from all of the fields of a structure, you can write a custom function that replaces the field values with `double` numbers. Use the example function castStructToDbl as a template.

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function castStructFromDbl as a template.

Check for Mismatched Data Types with Model Advisor

To detect when the data types of structure fields are not consistent with the associated bus signal elements, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink "Check structure parameter usage with bus signals"** check.

Limitations for Virtual Buses Crossing Model Reference Boundaries

If you use a bus signal as an input to or an output from a referenced model (`Model` block):

- You cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

  As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.
- You cannot configure function prototype control for the referenced model.

  As a workaround, use a nonvirtual bus instead.

For more information about using buses as inputs to or outputs from a referenced model, see "Bus Data Crossing Model Reference Boundaries" on page 63-119. For more information about bus virtuality, see "Virtual and Nonvirtual Buses" on page 63-14.

Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) are generated in the following structures:

- Block IO
- States
- External inputs

- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {
  real_T a;
  real_T b;
} BusObject;

/* Block signals (auto storage) */
typedef struct {
  BusObject ForEachSubsystem_IterInp_0[2];
} BlockIO_aob1;
```

For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Group Signals into Structures in the Generated Code Using Buses”.

Related Examples

- “Group Signals into Structures in the Generated Code Using Buses”
- “Use Different Sample Times for Signal Elements in a Bus” on page 63-75

Composite Signal Limitations

- Buses that contain signals of enumerated data types cannot pass through a block that requires a nonzero scalar initial value (such as a `Unit Delay` block).
- Root level bus outputs cannot be logged when you select the **Configuration Parameters > Data Import/Export > Output** parameter. Use standard signal logging instead, as described in "Export Signal Data Using Signal Logging" on page 59-56.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends `(signal#)` to all input signal names, where # is the input port index.

About Variable-Size Signals

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. For information about these types of signals, see “Signal Basics” on page 62-2 in the *Simulink User's Guide*.

A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

Creating Variable-Size Signals

You can create variable-size signals in your Simulink model by using:

- Switch or Multiport Switch blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A selector block and the `Starting and ending indices (port)` indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.

How Variable-Size Signals Propagate

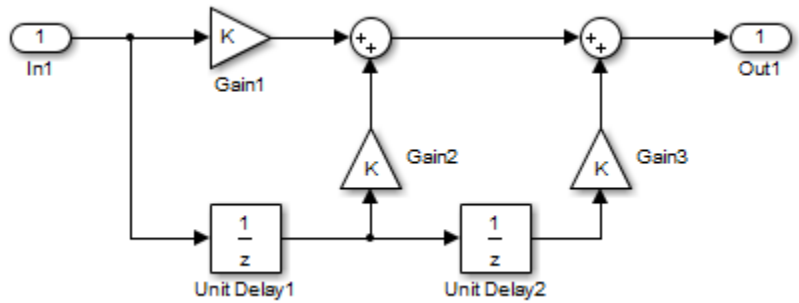
In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

  Various blocks in the model modify the sizes of the signals during execution of the output method.
- **Only during initialization of conditionally executed subsystems.**

  Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.



Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

"Mode-Dependent Variable-Size Signals" on page 64-14 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

Empty Signals

An empty signal is a signal with a length of `0`. For example, signals with size `[0]`, `[0x3]`, `[2x0]`, and `[2x0x3]` are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

Subsystem Initialization of Variable-Size Signals

The initial signal size from an Outport block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to `During execution`, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

Initial output parameter	Initial output signal size
A nonscalar matrix	The initial output signal size is the size of the **Initial output** parameter.
A scalar	The initial output signal size is a scalar.
The default []	The initial output size is an empty signal (dimensions are all zeros).

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to `Only when enabling`, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Outport block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the **Initial output** parameter is the default value `[]`, Simulink treats the initial output as a grounded value.
- If the model does not activate the parent subsystem at start time (`t = 0`), the current size of the subsystem output corresponding to the Outport block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

Simulink Models Using Variable-Size Signals

In this section...
"Variable-Size Signal Generation and Operations" on page 64-6
"Variable-Size Signal Length Adaptation" on page 64-10
"Mode-Dependent Variable-Size Signals" on page 64-14

Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

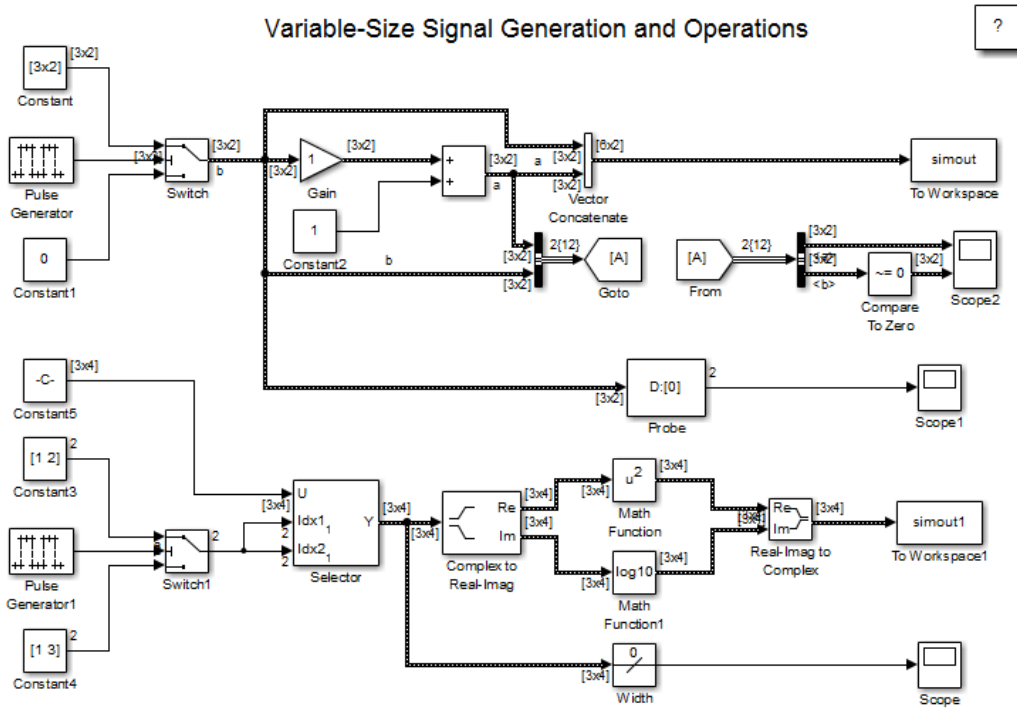
For a complete list of blocks that support variable-size signals, see "Simulink Block Support for Variable-Size Signals" on page 64-23.

1. In the MATLAB Command Window, type

   ```
   sldemo_varsize_basic
   ```

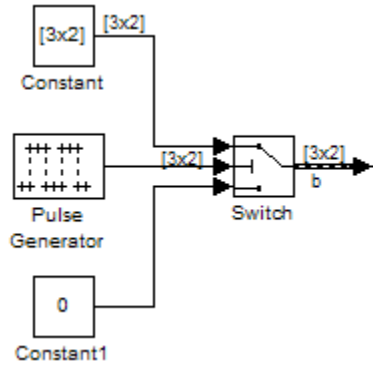
2. In the Simulink Editor, select **Display > Signals & Ports > Signal Dimensions**. Run a simulation or press `Ctrl-D`.

   The Simulink Editor displays the signal dimensions and line styles. See "Signal Basics" on page 62-2 for an interpretation of signal line styles.



Creating a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.



Output from the Switch block is a 2-D variable-size signal with a maximum size of `3x2`. When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

Saving Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2` The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values

ans(:,:,1) =

     1    -1
    -2     2
    -3     3

ans(:,:,2) =

     1    -1
    -2     2
    -3     3

ans(:,:,3) =
```

```
     0    NaN
   NaN    NaN
   NaN    NaN
```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

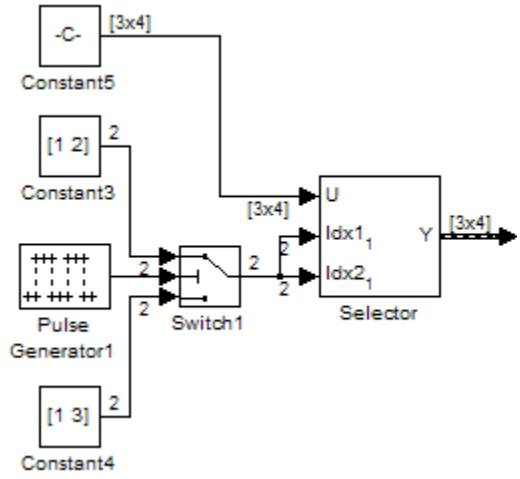
The signal dimensions for the first three time steps are shown.

```
ans =

     3     2
     3     2
     1     1
```

Creating a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a `3x4` matrix. The Pulse Generator represents a control signal that selects a starting and ending index value (`[1 2]` or `[1 3]`). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.



Viewing Changes in Signal Size

The output from the Selector block is either a `2x2` or `3x3` matrix. Because the maximum dimension for a variable-size signal is the `3x4` matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

Processing Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain block, the Sum block, the Math Function block, the Matrix Concatenate block. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

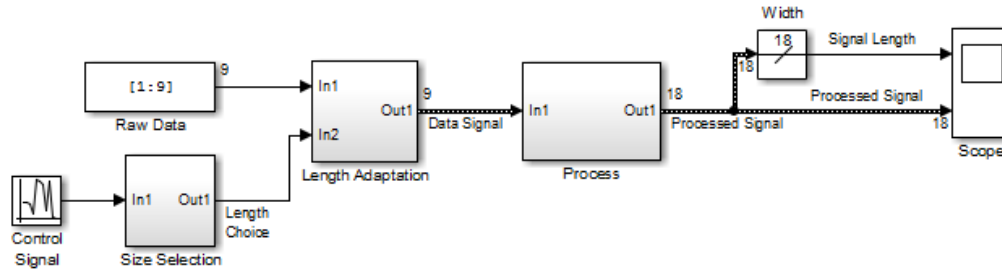
Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 64-23.

To open the example model, in the MATLAB Command Window, type:

```
sldemo_varsize_dataLengthAdapt
```



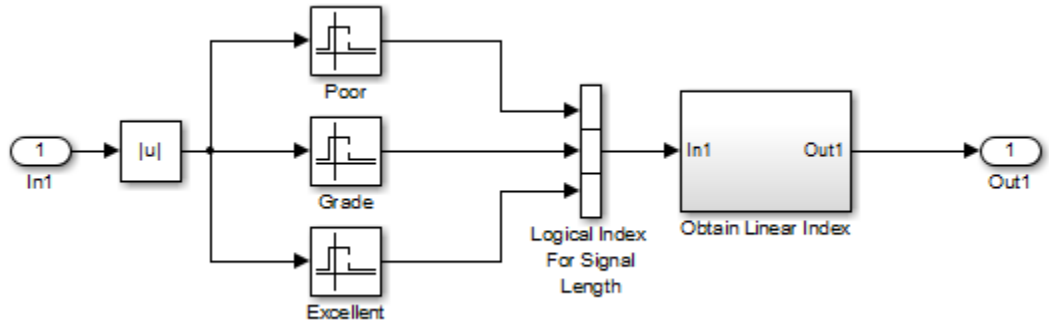
Creating a Variable-Size Signal by Adapting the Length of a Data Signal

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

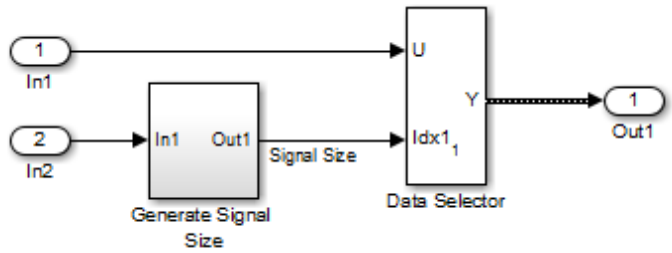
```
[1:9].'

ans =
     1
     2
     3
     4
     5
     6
     7
     8
     9
```

The Size Selection subsystem determines the quality of the data signal and outputs a quality value (1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

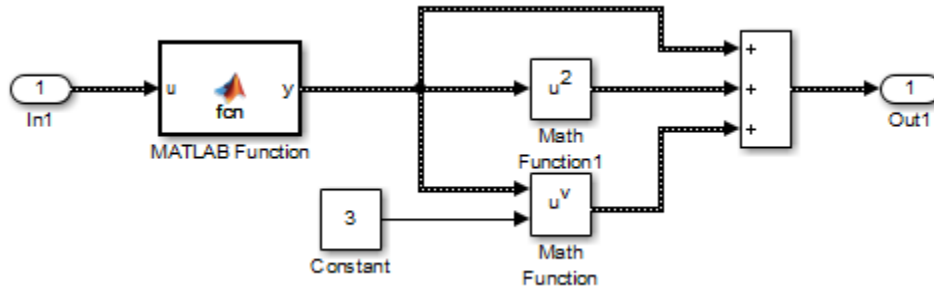


In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.



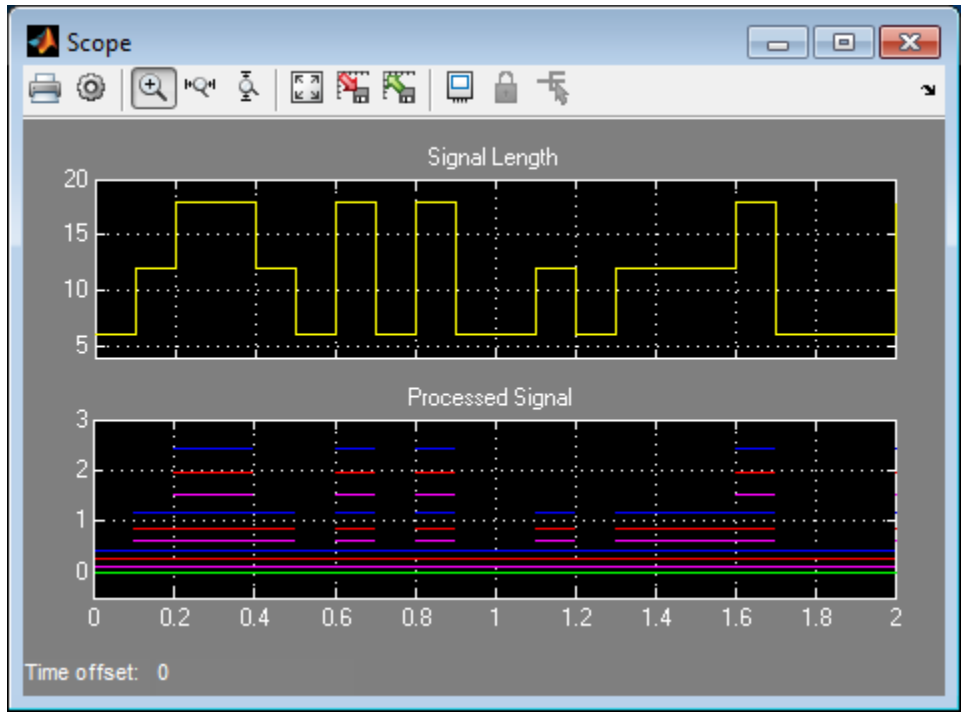
Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks shows various manipulations you can do with variable-size signals.



Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.



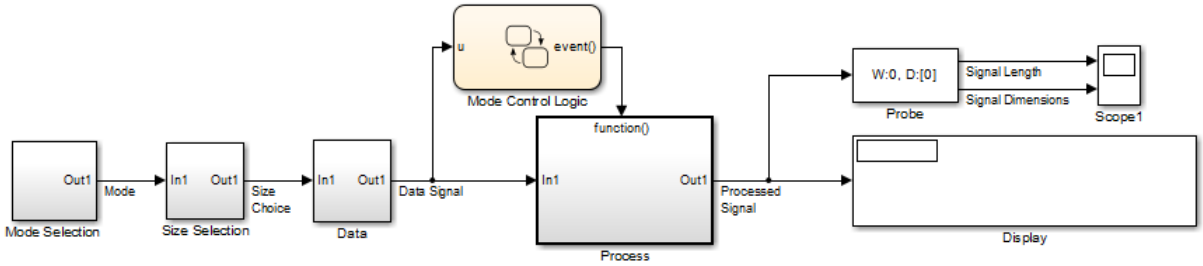
Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

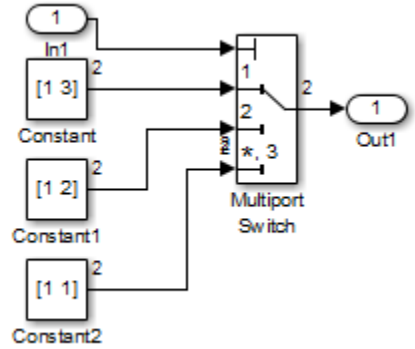
```
sldemo_varsize_multimode
```



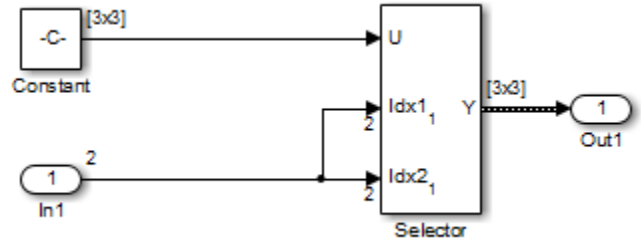
Creating a Variable-Size Signal Based on Mode

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value (1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are `[1 3]`, `[1 2]`, and `[1 1]`.



The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3x3, 2x2, and 1x1.



The dimensions of the raw data signal (Constant block) is a 3x3. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values

ans(:,:,1) =

     1     4     7
     2     5     8
     3     6     9
```

The variable-size signal generated from the Data subsystem is also a 3x3 matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values

ans(:,:,1) =

     1   NaN   NaN
   NaN   NaN   NaN
   NaN   NaN   NaN

ans(:,:,2) =

     1     4   NaN
     2     5   NaN
   NaN   NaN   NaN

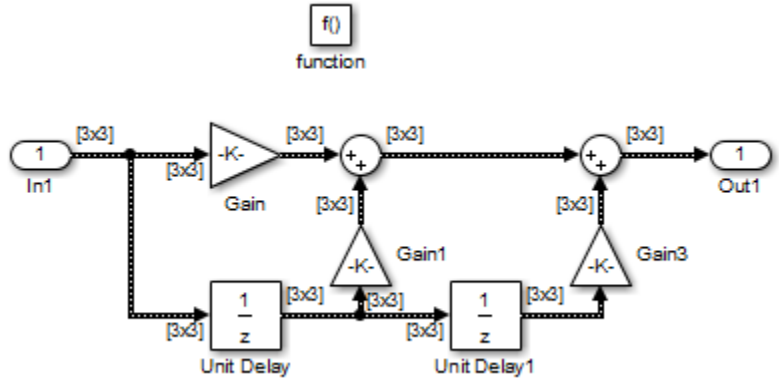
ans(:,:,3) =

     1     4     7
     2     5     8
     3     6     9
```

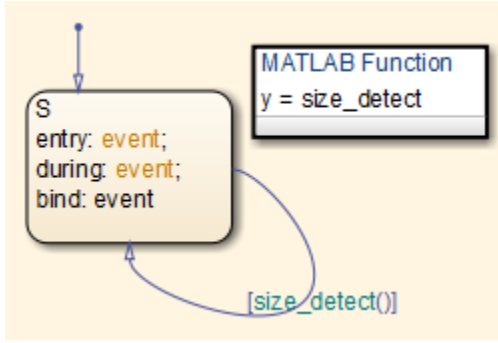
Processing a Variable-Size Signal with a Conditionally Executed Subsystem

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose `Only when enabling`. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 64-2.

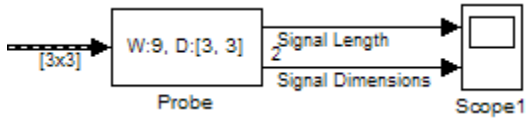


The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

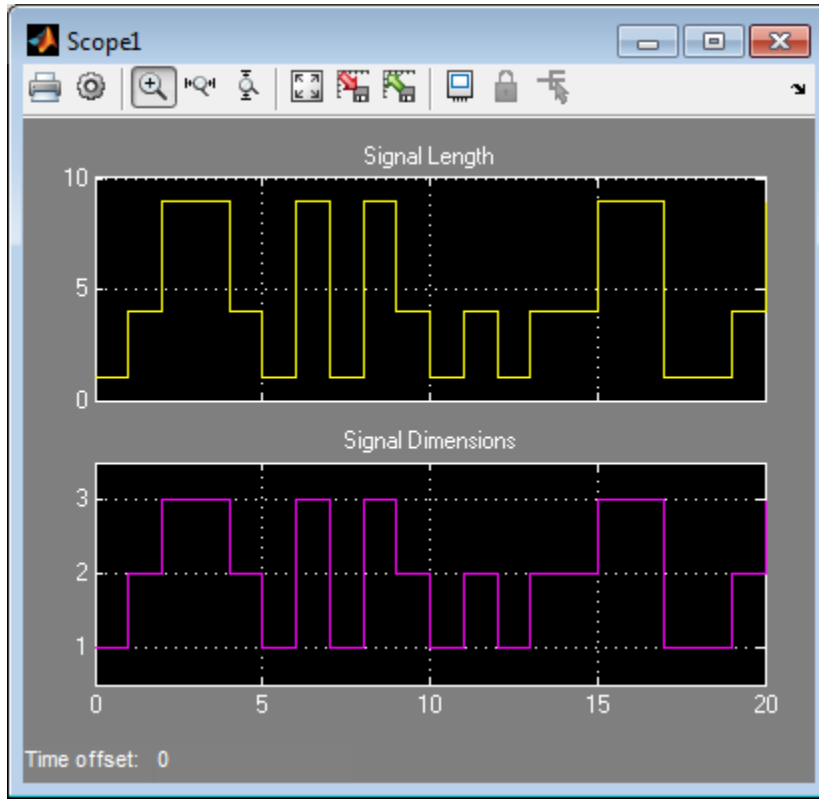


Visualizing Data

Use the Probe block to visualize signal size and signal dimension.



Since the signals are `n x n` matrices, the signal dimension lines overlap in the Scope display.



You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

S-Functions Using Variable-Size Signals

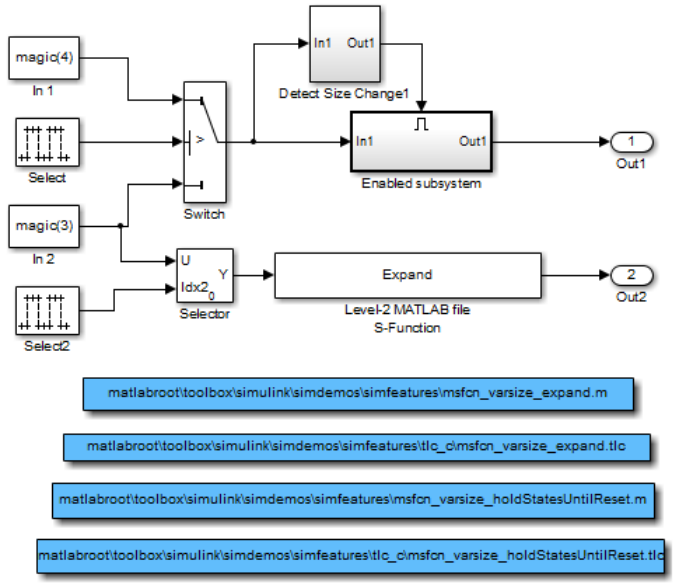
In this section...
“Level-2 MATLAB S-Function with Variable-Size Signals” on page 64-20 “C S-Function with Variable-Size Signals” on page 64-21

Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to `Variable`. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcndemo_varsize
```



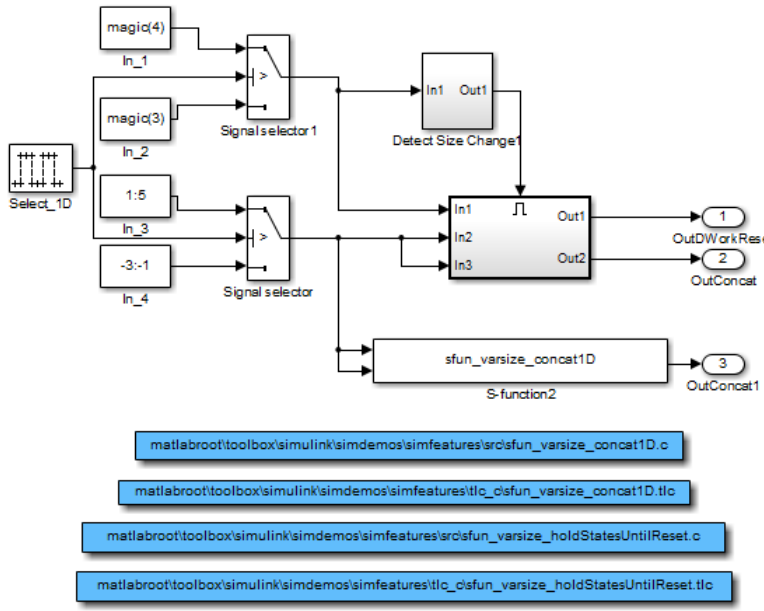
The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by `1:n` where `n` is the input value.

C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcndemo_varsize
```



The enabled subsystems have two S-Functions:

- sfun_varsize_holdStatesUntilReset is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.

- sfun_varsize_concat1D is a C S-function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

Simulink Block Support for Variable-Size Signals

In this section...
“Simulink Block Data Type Support” on page 64-23
“Conditionally Executed Subsystem Blocks” on page 64-23
“Switching Blocks” on page 64-24

Simulink Block Data Type Support

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

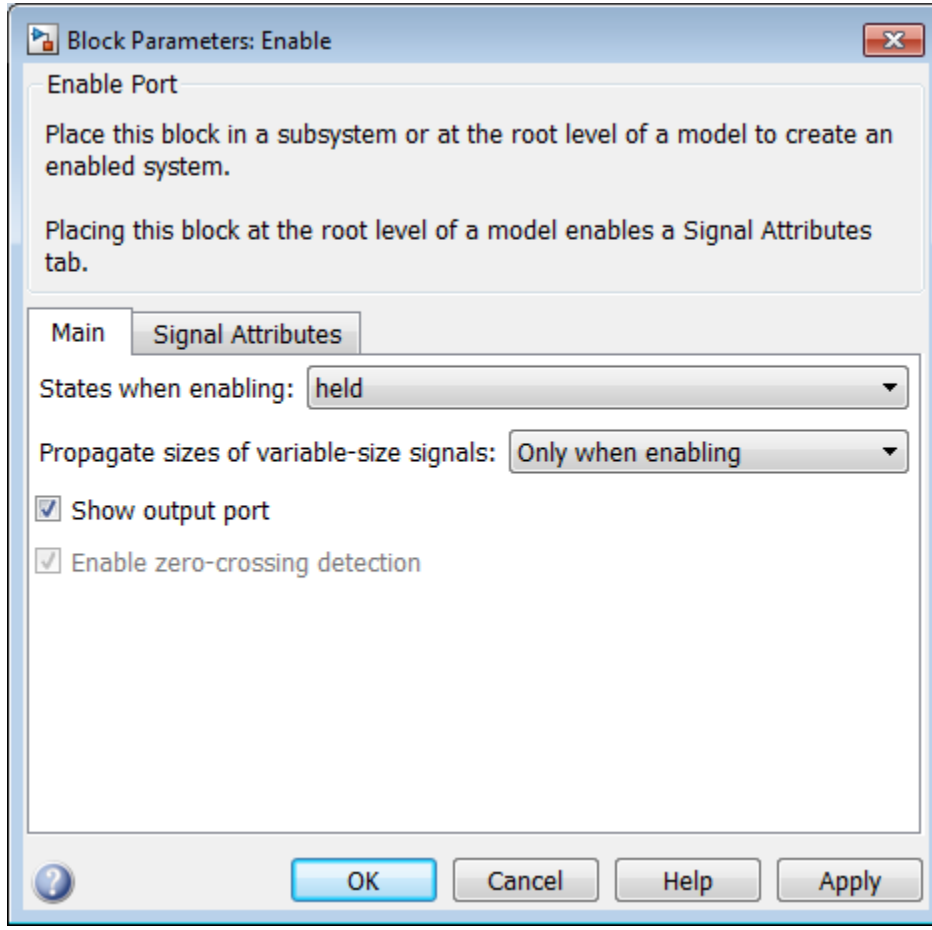
1. Open a Simulink model.
2. Select **Help > Simulink > Block Data Types & Code Generation Support > Simulink**.

An `X` in the **Variable-Size Support** column indicates support for that block.

Tip You can also view the table by entering showblockdatatypetable at the command prompt.

Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to `During exection`, `Only when execution is resumed` (Action Port), and `Only when enabling` (Enable and Trigger or Function-Call).

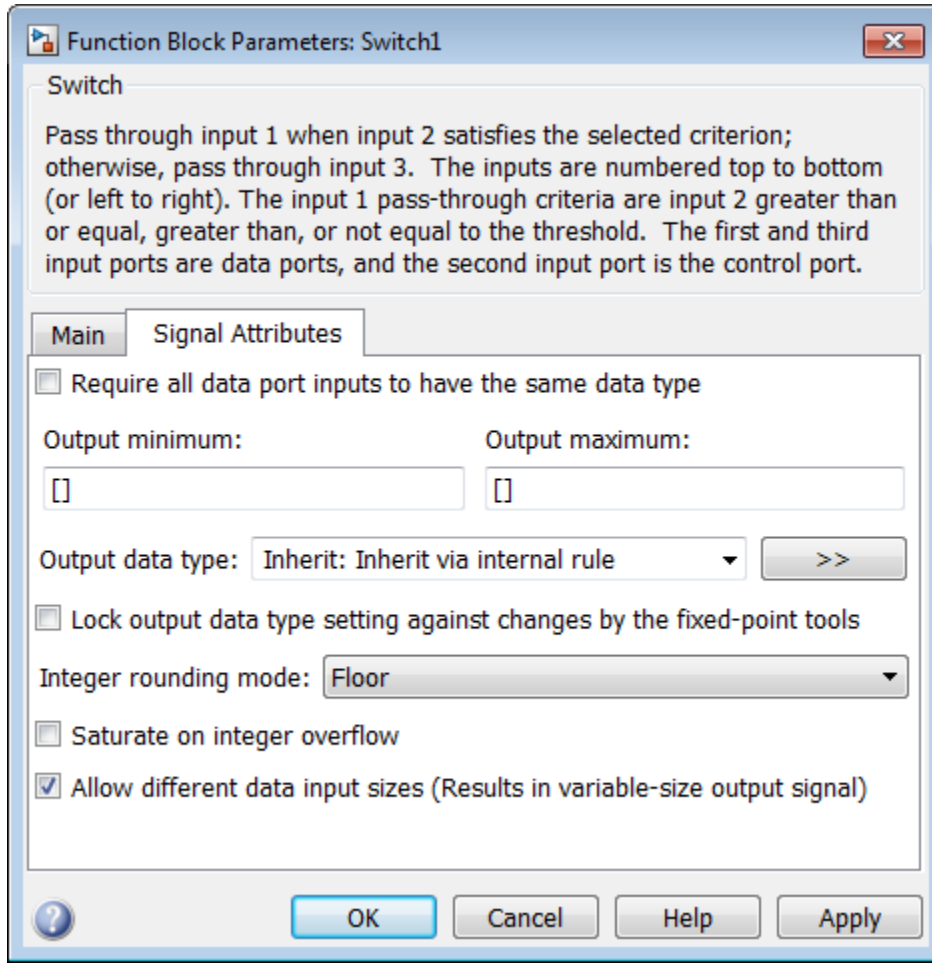


- `Action Port`
- `Enable`
- `Trigger` — **Trigger type** set to `function-call`

Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the

Allow different data input sizes parameter for these blocks on the Signal Attributes pane to either on or off.



- `Switch`
- `Multiport Switch`
- `Manual Switch`

Variable-Size Signal Limitations

The following table is a list of known limitations and workarounds.

Limitation	Workaround
Array format logging does not support variable-size signals.	Use a `Structure` or `Structure With Time` format for logging variable-size signals.
Right-click signal logging does not support variable-size signals.	Use a To Workspace block (with `Structure` or `Structure With Time` format) or a root Outport block for logging variable-size signals.
A frame-based variable-size signal cannot change the frame length (first dimension size), but it can change the second dimension size (number of channels). Using frame-based signals requires DSP System Toolbox software.	Use the Frame Conversion block to convert a signal into sample-based signal.
Variable-size signals must have a discrete sample time.	—
Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR, C++ interface, and the ERT reusable code interface.	—
Simulink does not support variable-size parameter or DWork vectors.	—
Rapid accelerator mode does not support models having root-level input ports with variable-size signals.	—
Virtual buses that you use as inputs to or outputs from a referenced model (`Model` block) do not support variable-size signals.	Configure the bus signal as nonvirtual. For more information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 63-119. For more information about controlling

Limitation	Workaround
	bus virtuality, see “Virtual and Nonvirtual Buses” on page 63-14.

About Adding Items

You can add commands and submenus to the following menu locations for the Simulink Editor and Stateflow Editor:

- The end of top-level menus
- The menu bar
- The beginning or end of a context menu

To add an item to an editor menu:

- For each item, create a function, called a *schema function*, that defines the item (see "Define Menu Items" on page 65-4).
- Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see "Register Menu Customizations" on page 65-9).
- Create callback functions that implement the commands triggered by the items that you add to the menus.

Code for Adding Menu Items

The following `sl_customization.m` file adds four items to the Simulink Editor's **Tools** menu.

```
function sl_customization(cm)
```

```
  %% Register custom menu function.
  cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
  schemaFcns = {@getItem1,...
      @getItem2,...
      {@getItem3,3}... %% Pass 3 as user data to getItem3.
      @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
  schema = sl_action_schema;
  schema.label = 'Item One';
  schema.userdata = 'item one';
  schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
  disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
  % Make a submenu label 'Item Two' with
  % the menu item above three times.
  schema = sl_container_schema;
  schema.label = 'Item Two';
 schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
  % Create a menu item whose label is
  % 'Item Three: 3', with the 3 being passed
  % from getMyItems above.

  schema = sl_action_schema;
  schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
        set_param(gcs, 'ScreenColor', 'red');
    else
        set_param(gcs, 'ScreenColor', 'white');
    end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
  schema = sl_toggle_schema;
  schema.label = 'Red Screen';
  if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
    schema.checked = 'checked';
```

```
  else
    schema.checked = 'unchecked';
  end
  schema.callback = @myToggleCallback;
end
```

Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- "Defining Menu Items That Trigger Custom Commands" on page 65-4
- "Defining Custom Submenus" on page 65-7

Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see "Callback Info Object" on page 65-10) and create and return an action schema object (see "Action Schema Object" on page 65-5) that specifies the item's label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```
function schema = getItem1(callbackInfo)

  %% Create an instance of an action schema.
  schema = sl_action_schema;

%% Specify the menu item's label.
  schema.label = 'My Item 1';
  schema.userdata = 'item1';
  %% Specify the menu item's callback function.
  schema.callback = @myCallback1;

end

function myCallback1(callbackInfo)
  disp(['Callback for item ' callbackInfo.userdata
        ' was called']);
end
```

Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include

- `tag`

  Optional string that identifies this action, for example, so that it can be referenced by a filter function.

- `label`

  String specifying the label that appears on a menu item that triggers this action.

- `state`

  Property that specifies the state of this action. Valid values are `'Enabled'` (the default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  String specifying text to appear in the editor's status bar when the user selects the menu item that triggers this action.

- `userdata`

  Data that you specify. May be of any type.

- `accelerator`

  String specifying a keyboard shortcut that a user can use to trigger this action. You can add a keyboard shortcut only for items that appear on menu bar menus. Use the form `'Ctrl+K'`, where *K* is the shortcut key. For example, `'Ctrl+T'` specifies that the user can invoke this action by holding down **Ctrl** and pressing **T**.

- `callback`

  String specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include

- `tag`

  Optional string that identifies this toggle action, for example, so that it can be referenced by a filter function.

- `label`

  String specifying the label that appears on a menu item that triggers this toggle action.

- `checked`

  Specify whether the menu item displays a check mark. Valid values are `'unchecked'` (default) and `'checked'`

- `state`

  String that specifies the state of this toggle action. Valid values are `'Enabled'` (default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  String specifying text to appear in the editor's status bar when the user selects the menu item that triggers this toggle action.

- `userdata`

  Data that you specify. May be of any type.

- `accelerator`

String specifying a keyboard shortcut that a user may use to trigger this action. The string must be of the form `'Ctrl+K'`, where *K* is the shortcut key. For example, `'Ctrl+T'` specifies that the user may invoke this action by holding down the **Ctrl** key and pressing the **T** key.

- `callback`

  String specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see "Container Schema Object" on page 65-7) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in "Defining Menu Items That Trigger Custom Commands" on page 65-4.

```
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```

Container Schema Object

A container schema object specifies a submenu's label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- `tag`

  Optional string that identifies this submenu.

- `label`

  String specifying the submenu's label.

- `state`

  String that specifies the state of this submenu. Valid values are `'Enabled'` (the default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  String specifying text to appear in the editor's status bar when the user selects this submenu.

- `childrenFcns`

  Cell array that specifies the contents of the submenu. Each entry in the cell array can be

  - A pointer to a schema function that defines an item on the submenu (see "Define Menu Items" on page 65-4)
  - A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see "Callback Info Object" on page 65-10) passed to the schema function
  - `'separator'`, which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, `'SEPARATOR'` and `'Separator'` are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).

  For example, the following cell array specifies two submenu entries:

  ```
  {@getItem1, 'separator', {@getItem2, 1}}
  ```

  In this example, a 1 is passed to `getItem2` via a callback info object.

- `generateFcn`

Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

Note: The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

- `userdata`

  Data of any type that is passed to `generateFcn`.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see "Registering Customizations" on page 65-25) to perform this task. In particular, for each menu that you want to customize, your system's `sl_customization` function must invoke the customization manager's `addCustomMenuFcn` method (see "Customization Manager" on page 65-25). Each invocation should pass the tag of the menu (see "Menu Tags" on page 65-11) to be customized and a custom menu function that specifies the items to be added to the menu (see "Creating the Custom Menu Function" on page 65-10) . For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
  %% Register custom menu function.
  cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see "Define Menu Items" on page 65-4). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see "Callback Info Object" on page 65-10) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
  schemas = {@getItem1, ...
           @getItem2, ...
             {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`

  Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.

- `model`

  Method to get the handle to the model being displayed in the editor window.

- `userdata`

  User data property. The value of this property can be any type of data.

Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive

or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

Menu Tags

A menu tag is a string that identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know a menu's tag to add custom items to it (see "Register Menu Customizations" on page 65-9). You can configure the editor to display all (see "Displaying Menu Tags" on page 65-12) but the following tags:

Tag	Add...
Simulink tags	
`Simulink:MenuBar`	Menu to Simulink Editor's menu bar
`Simulink:PreContextMenu`	Item to the beginning of Simulink Editor's context menu
`Simulink:ContextMenu`	Item to the end of Simulink Editor's context menu
`Simulink:FileMenu`	Item near the end of the Simulink Editor's **File** menu, but before the **Exit MATLAB** item
`Simulink:EditMenu`	Item to the end of the Simulink Editor's **Edit** menu
`Simulink:ViewMenu`	Item to the end of the Simulink Editor's **View** menu
`Simulink:DisplayMenu`	Item to the end of the Simulink Editor's **Display** menu
`Simulink:DiagramMenu`	Item to the end of the Simulink Editor's **Diagram** menu
`Simulink:SimulationMenu`	Item to the end of the Simulink Editor's **Simulation** menu
`Simulink:AnalysisMenu`	Item to the end of the Simulink Editor's **Analysis** menu
`Simulink:CodeMenu`	Item to the end of the Simulink Editor's **Code** menu
`Simulink:ToolsMenu`	Item to the end of the Simulink Editor's **Tools** menu
`Simulink:HelpMenu`	Item to the end of Simulink Editor's **Help** menu

Tag	Add...
Stateflow tags	
`Stateflow:MenuBar`	Menu to Stateflow Editor's menu bar
`Stateflow:PreContextMenu`	Item to the beginning of Stateflow Editor's context menu.
`Stateflow:ContextMenu`	Items to the end of Stateflow Editor's context menu.
`Stateflow:FileMenu`	Item near the end of the Stateflow Editor's **File** menu, but before the **Exit MATLAB** item
`Stateflow:EditMenu`	Item to the end of Stateflow Editor's **Edit** menu
`Stateflow:ViewMenu`	Item to the end of the Stateflow Editor's **View** menu
`Stateflow:DisplayMenu`	Item to the end of the Stateflow Editor's **Display** menu
`Stateflow:ChartMenu`	Item to the end of the Stateflow Editor's **Chart** menu
`Stateflow:SimulationMenu`	Item to the end of the Stateflow Editor's **Simulation** menu
`Stateflow:AnalysisMenu`	Item to the end of the Stateflow Editor's **Analysis** menu
`Stateflow:CodeMenu`	Item to the end of the Stateflow Editor's **Code** menu
`Stateflow:ToolsMenu`	Item to the end of the Stateflow Editor's **Tools** menu
`Stateflow:HelpMenu`	Item to the end of the Stateflow Editor's **Help** menu

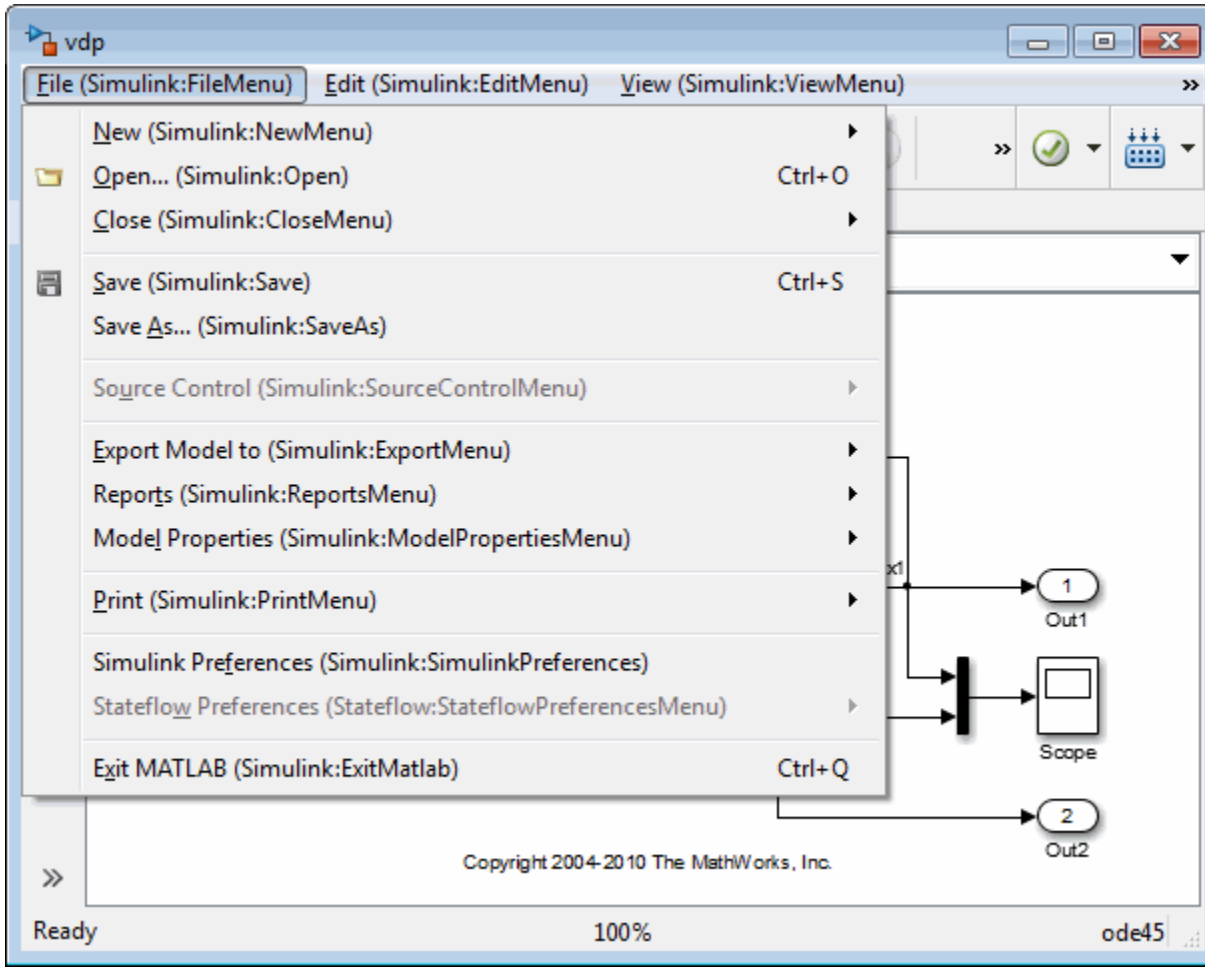
Displaying Menu Tags

You can configure the Simulink and Stateflow software to display the tag for a menu item next to the item's label, allowing you to determine at a glance the tag for a menu. The `Simulink:TagName` customizations appear only if the current editor is the Simulink Editor. The `Stateflow:TagName` customizations appear only if the current editor is the Stateflow Editor.

To configure the editor to display menu tags, at the MATLAB command line, set the customization manager's `showWidgetIdAsToolTip` property to `true`. For example:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip=true;
```

The tag of each menu item appears next to the item's label on the menu:



To turn off tag display, enter the following command at the command line:

```
cm.showWidgetIdAsToolTip=false;
```

Note: Some menu items may not work while menu tag display is enabled. To ensure that all items work, turn off menu tag display before using the menus.

Simulink and Stateflow Editor Menu Customization

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

Disable and Hide Model Editor Menu Items

In this section...
“About Disabling and Hiding Model Editor Menu Items” on page 65-15
“Example: Disabling the New Model Command on the Simulink Editor's File Menu” on page 65-15
“Creating a Filter Function” on page 65-15
“Registering a Filter Function” on page 65-16

About Disabling and Hiding Model Editor Menu Items

You can disable or hide items that appear on the Simulink model editor menus. To disable or hide a menu item, you must:

- Create a filter function that disables or hides the menu item (see “Creating a Filter Function” on page 65-15).
- Register the filter function with the customization manager (see “Registering a Filter Function” on page 65-16).

For more information on Model Editor menu items, see:

Example: Disabling the New Model Command on the Simulink Editor's File Menu

```
function sl_customization(cm)
  cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
  state = 'Disabled';
end
```

Creating a Filter Function

Your filter function must accept a callback info object and return a string that specifies the state that you want to assign to the menu item. Valid states are

- `'Hidden'`

- `'Disabled'`
- `'Enabled'`

Your filter function may have to compete with other filter functions and with Simulink itself to assign a state to an item. Who succeeds depends on the strength of the state that each assigns to the item. `'Hidden'` is the strongest state. If any filter function or Simulink assigns `'Hidden'` to the item, it is hidden. `'Enabled'` is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign `'Enabled'`to the item. The `'Disabled'` state is of middling strength. It overrides `'Enabled'` but is itself overridden by `'Hidden'`. For example, if any filter function or Simulink or Stateflow assigns `'Disabled'` to a menu item and none assigns `'Hidden'` to the item, the item is disabled.

Note: The Simulink software does not allow you to filter some menu items, for example, the **Exit MATLAB** item on the Simulink **File** menu. An error message is displayed if you attempt to filter a menu item that you are not allowed to filter.

Registering a Filter Function

Use the customization manager's `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or menu item to be filtered (see “Displaying Menu Tags” on page 65-12) and a pointer to the filter function itself. For example, the following code registers a filter function for the **New Model** item on the Simulink **File** menu.

```
function sl_customization(cm)
  cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

Disable and Hide Dialog Box Controls

In this section...

"About Disabling and Hiding Controls" on page 65-17
"Disable a Button on a Dialog Box" on page 65-17
"Write Control Customization Callback Functions" on page 65-18
"Dialog Box Methods" on page 65-19
"Dialog Box and Widget IDs" on page 65-19
"Register Control Customization Callback Functions" on page 65-20

About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as *widgets*), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whetherother dialog boxes are customizable, open the dialog box, enable dialog and widget ID display (see "Dialog Box and Widget IDs" on page 65-19), and hover over a widget. If a widget ID appears, the dialog box is customizable.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see "Write Control Customization Callback Functions" on page 65-18) and registering the callback functions using the customization manager (see "Register Control Customization Callback Functions" on page 65-20). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

Disable a Button on a Dialog Box

This `sl_customization.m` file disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box.
cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBrowseButton)
% Disable for Configuration Parameters dialog box
cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBrowseButton)

end

function disableRTWBrowseButton(dialogH)
  hSrc   = dialogH.getSource;  % Simulink.RTWCC
  hModel = hSrc.getModel;
  modelName   = get_param(hModel,'Name');

  if ~isempty(strfind(modelName,'engine'))
    % Takes a cell array of widget Factory ID.
    dialogH.disableWidgets({'Tag_ConfigSet_RTW_Browse'})
  end

end
```

To test this customization:

1. Save the `sl_customization.m` file on the MATLAB path.
2. Refresh the customizations by entering `sl_refresh_customizations` at the command line or by restarting MATLAB (see "Registering Customizations" on page 65-25).
3. Open the `sldemo_engine` model, for example, by entering the command `sldemo_engine` at the command prompt.
4. Open the Configuration Parameters dialog box and look at the **Code Generation** pane to see if the **Browse** button is disabled.

Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function disableRTWBrowseButton(dialogH)

  hSrc   = dialogH.getSource;  % Simulink.RTWCC
  hModel = hSrc.getModel;
  modelName   = get_param(hModel,'Name');

  if ~isempty(strfind(modelName,'engine'))
     % Takes a cell array of widget Factory ID.
     dialogH.disableWidgets({'Tag_ConfigSet_RTW_Browse'})
  end
```

Dialog Box Methods

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

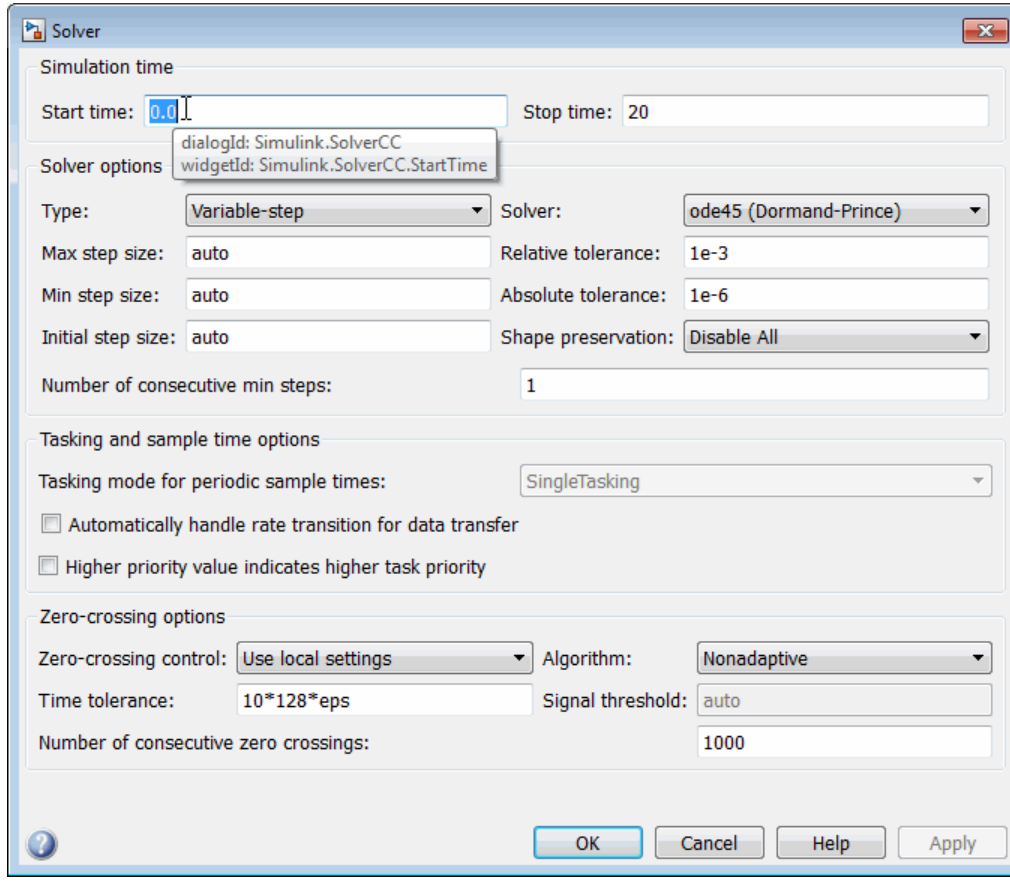
`widgetIDs` is a cell array of widget identifiers (see “Dialog Box and Widget IDs” on page 65-19) that specify the widgets to disable or hide.

Dialog Box and Widget IDs

Dialog box and widget IDs are strings that identify a control on a Simulink dialog box. To determine the dialog box and widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the dialog box and the widget IDs. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the dialog box ID for the **Solver** pane is `Simulink.SolverCC` and the widget ID for the **Start time** field is `Simulink.SolverCC.StartTime`.



Note: The tooltip displays `not customizable` for controls that are not customizable.

Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation's `sl_customization.m` file (see "Registering Customizations" on page 65-25) that invokes the customization manager's `addDlgPreOpenFcn` on the callbacks.

`addDlgPreOpenFcn` takes two arguments. The first argument is a dialog box ID (see "Dialog Box and Widget IDs" on page 65-19) and the second is a pointer to the callback function to register. Invoking this method causes the registered function to be invoked for each dialog box of the type specified by the dialog box ID. The function is invoked before the dialog box is opened.

This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see "Write Control Customization Callback Functions" on page 65-18).

```
function sl_customization(cm)

  % Disable for standalone Configuration Parameters dialog box.
  cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBrowseButton)

  % Disable for Configuration Parameters dialog box.
   cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBrowseButton)

end
```

Note: Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method's dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

Customize the Library Browser

In this section...
"Reorder Libraries" on page 65-22
"Disable and Hide Libraries" on page 65-22
"Reorder Blocks in Libraries" on page 65-23

Reorder Libraries

The order in which a library appears in the Library Browser is determined by its name and its sort priority. Libraries appear in the Library Browser's tree view in ascending order of priority, with all blocks having the same priority sorted alphabetically. The Simulink library has a sort priority of `-1` by default; all other libraries, a sort priority of `0`. This guarantees that the Simulink library is by default the first library displayed in the Library Browser. You can reorder libraries by changing their sort priorities.
To change library sort priorities, insert a line of code of the following form in an `sl_customization.m` file (see "Registering Customizations" on page 65-25) on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder( {'LIBNAME1', PRIORITY1, ...
                                         'LIBNAME2, 'PRIORITY2, ...
                                          .
                                          .
                                         'LIBNAMEN', PRIORITYN} );
```

where `LIBNAMEn` is the name of the library or its model file and `PRIORITYn` is an integer indicating the library's sort priority. For example, the following code moves the Simulink Extras library to the top of the Library Browser's tree view.

```
cm.LibraryBrowserCustomizer.applyOrder( {'Simulink Extras', -2} );
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code of the following form in an `sl_customization.m` file (see "Registering Customizations" on page 65-25) on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyFilter( {'PATH1', 'STATE1', ...
                                          'PATH2', 'STATE2', ...
                                          .
                                          .
                                          'PATHN', 'STATEN'} );
```

where `PATHn` is the path of the library, sublibrary, or block to be disabled or hidden and `'STATEn'` is `'Disabled'` or `'Hidden'`. For example, the following code hides the Simulink Sources sublibrary and disables the Sinks sublibrary.

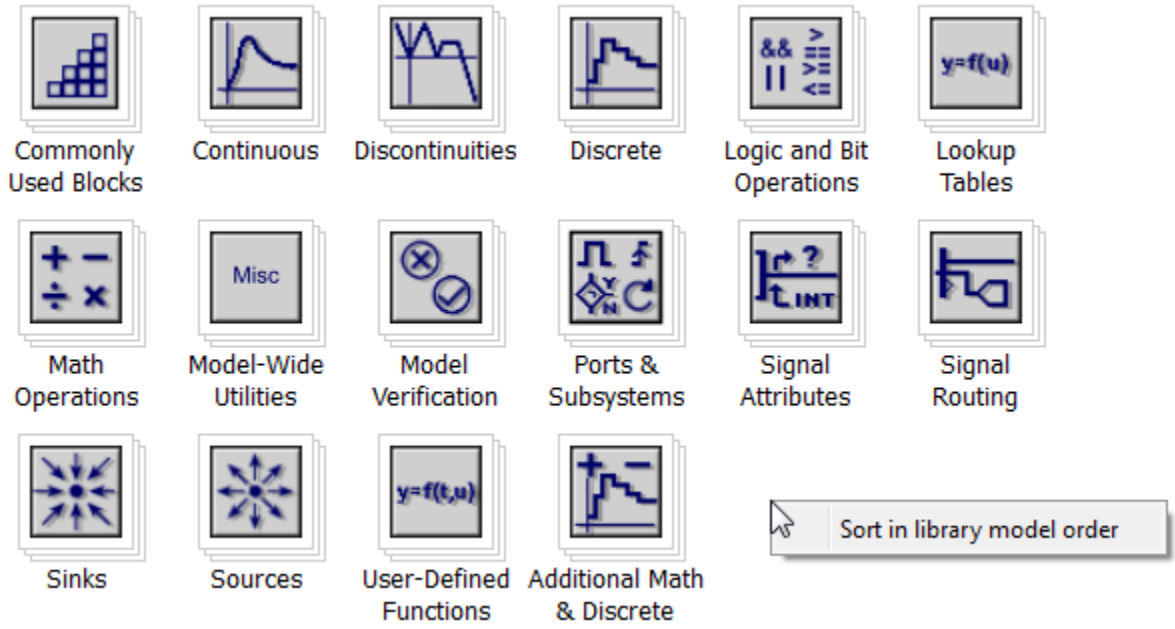
```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources','Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks','Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Reorder Blocks in Libraries

You can order blocks in the Library Browser alphabetically or based on their layout in the underlying library model. This library model can be a built-in block library or your custom library model.

To reorder the display of blocks in all libraries in the Library Browser, right-click in the blocks pane and select **Sort in library model order** or **Sort in alphabetical order**. This setting stays in effect from session to session.



Note: Customized sorting in the Library Browser takes precedence over library model order or alphabetical order sorting. In the figure, the blocks pane for the `Simulink` library shows the `Additional Math & Discrete` sublibrary last because of custom sorting rules applied to this sublibrary.

Registering Customizations

In this section...
“About Registering User Interface Customizations” on page 65-25
“Customization Manager” on page 65-25

About Registering User Interface Customizations

You must register your user interface customizations using a MATLAB function called `sl_customization.m`. This is located on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function should accept one argument: a handle to a customization manager object. For example:

```
function sl_customization(cm)
```

The customization manager object includes methods for registering menu and control customizations (see “Customization Manager” on page 65-25). Your instance of the `sl_customization` function should use these methods to register customizations specific to your application. For more information, see the following sections on performing customizations.

- “Add Items to Model Editor Menus” on page 65-2
- “Disable and Hide Model Editor Menu Items” on page 65-15
- “Disable and Hide Dialog Box Controls” on page 65-17

The `sl_customization.m` file is read when the Simulink software starts. If you subsequently change the `sl_customization.m` file, you must restart the Simulink software or enter the following command at the command line to effect the changes:

```
sl_refresh_customizations
```

Customization Manager

The customization manager includes the following methods:

- `addCustomMenuFcn(stdMenuTag, menuSpecsFcn)`

  Adds the menus specified by `menuSpecsFcn` to the end of the standard Simulink menu specified by `stdMenuTag`. The `stdMenuTag` argument is a string that specifies

the menu to be customized. For example, the `stdMenuTag` for the Simulink editor's **Tools** menu is `'Simulink:ToolsMenu'` (see “Displaying Menu Tags” on page 65-12 for more information). The `menuSpecsFcn` argument is a handle to a function that returns a list of functions that specify the items to be added to the specified menu. See “Add Items to Model Editor Menus” on page 65-2 for more information.

- `addCustomFilterFcn(stdMenuItemID, filterFcn)`

  Adds a custom filter function specified by `filterFcn` for the standard Simulink model editor menu item specified by `stdMenuItemID`. The `stdMenuItemID` argument is a string that identifies the menu item. For example, the ID for the **New Model** item on the Simulink editor's **File** menu is `'Simulink:NewModel'` (see “Displaying Menu Tags” on page 65-12 for more information) . The `filterFcn` argument is a pointer to a function that hides or disables the specified menu item. See “Disable and Hide Model Editor Menu Items” on page 65-15 for more information.

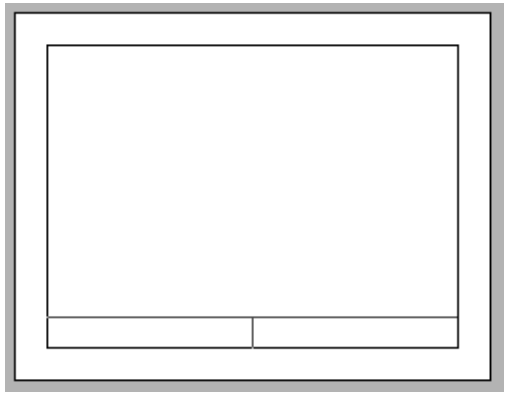
Print Frames

In this section...
"What Are Print Frames?" on page 66-2
"PrintFrame Editor" on page 66-3
"Single Use or Multiple Use Print Frames" on page 66-4
"Text and Variable Content" on page 66-5

What Are Print Frames?

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

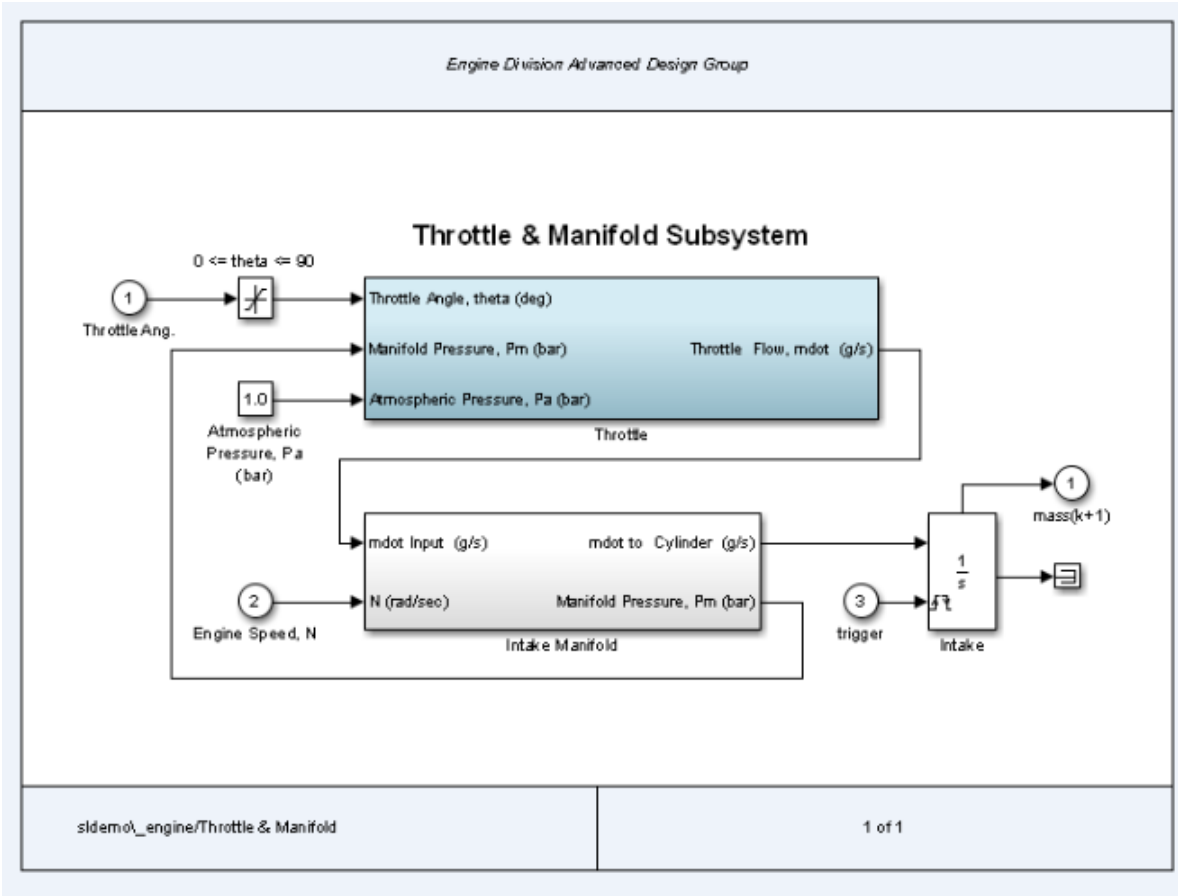


Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells.

For example, the print frame below includes:

- An additional row at the top of the frame for a title

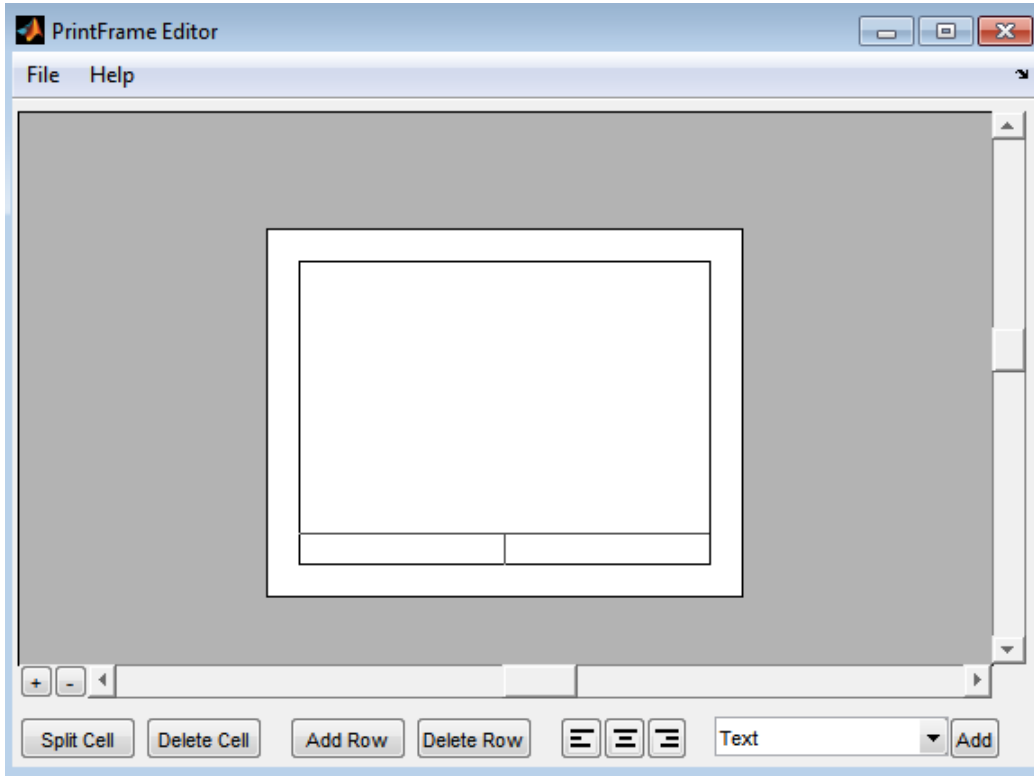
- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number



PrintFrame Editor

Use the PrintFrame Editor to create and edit print frames.

To open the PrintFrame Editor, at the MATLAB command line, enter the `frameedit` command.



Use the PrintFrame Editor to:

- Set up the printed page
- Add or remove rows and cells in the print frame
- Add content to cells, such as text, the date, and page numbers
- Format cell content

To open an existing print frame, use `frameedit` command with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

Single Use or Multiple Use Print Frames

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

Text and Variable Content

In cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

See Also

`frameedit`

Related Examples

- “Create a Print Frame” on page 66-6
- “Print Using Print Frames” on page 66-13

Create a Print Frame

1. At the MATLAB prompt, type `frameedit` to open the PrintFrame Editor.
2. In the PrintFrame Editor, select **File > Page Setup**.

   If necessary, change default page setup for the print frame, which is:

   - Paper type — usletter
   - Orientation — landscape

   Note: The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

   - Margins — .75 inches on all sides
3. Set up the layout of the print frame and add content. See:

   - "Add Rows and Cells to Print Frames" on page 66-7
   - "Add Content to Print Frame Cells" on page 66-9
4. Save the print frame as a `.fig` file. Select **File > Save As**.

Add Rows and Cells to Print Frames

In this section...
“Add and Remove Rows” on page 66-7
“Add and Remove Cells” on page 66-7
“Resize Rows and Cells” on page 66-7

Tip Specify the print frame page setup before you create rows and cells or add content (see “Create a Print Frame” on page 66-6).

Add and Remove Rows

You can add a row above the row that you select.

1. Click in a cell to select a row.

   When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.
2. Click **Add Row**.

   The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

Add and Remove Cells

You can add cells within a row.

1. Select the cell that you want to split.
2. Click **Split Cell**.

   The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

Resize Rows and Cells

You can change the dimensions of a row or cell by selecting the bordering line.

1 Click the line you want to move.

   A handle appears on both ends of the line.

2 Drag the line to resize the row or cell.

For example, to make a row taller, click on the top line that forms the row. Then drag the line up and the height of the row increases.

To change the overall dimensions of the print frame, see “Create a Print Frame” on page 66-6.

Related Examples

Add Content to Print Frame Cells

In this section...
"Types of Content" on page 66-9 "Add Content to Cells" on page 66-9 "Block Diagram" on page 66-10 "Variables" on page 66-10 "Text" on page 66-11 "Format Content in Cells" on page 66-12

Types of Content

You can add text or variables, or both, to a cell.

You must add a `Block Diagram` variable to one of the cells.

For details about the types of content, see:

- "Block Diagram" on page 66-10
- "Variables" on page 66-10
- "Text" on page 66-11

Add Content to Cells

1. Select the cell that you want to add content to.
2. From the list, select the type of content that you want to add.
3. Click **Add**.

   The type of content that you added appears in the cell.

   Tip If you click **Add** and nothing happens, it might be because you did not select a cell first.

4. If you add text, select the edit box and type in the text. For details, see "Text" on page 66-11.

Tip To make it easier to read and edit the content that you add, you can click the **Zoom in** + button.

Include Multiple Entries in a Cell

1. Select a cell that has a content entry.
2. Add another content type item from the list.

   The new entry is added after the last entry in that cell.

You can also add descriptive text to any of the variable entries without using the **Text** item.

1. Double-click in the cell.
2. Type text in the edit box before or after the entry.
3. To end editing mode, click outside of the cell.

Note: You cannot include multiple entries or text in the cell that contains the `Block Diagram` variable. `%<blockdiagram>` must be the only content in that cell.

Block Diagram

Use the `Block Diagram` variable to indicate the cell in which to print the block diagram. Every print frame must include one `Block Diagram` variable. If you do not specify a `Block Diagram` in one of the cells, you cannot save the print frame and cannot print a block diagram with it.

Do not add any other content in a cell that contains a `Block Diagram` variable.

Variables

In addition to the `Block Diagram` variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

Variable entries include:

- `Block Diagram` — Add this variable in the cell in which you want the block diagram to print. For details, see “Block Diagram” on page 66-10.

- `Date` — The date that the block diagram and print frame are printed, in `dd-mmm-yyyy` format.
- `Time` — The time that the block diagram and print frame are printed, in `hh:mm` format.
- `Page Number` — The page of the block diagram being printed.
- `Total Pages` — The total number of pages being printed for the block diagram, which depends on the printing options specified.
- `System Name` — The name of the block diagram being printed.
- `Full System Name` — The name of the block diagram being printed, including its position from the root system through the current system, for example, `engine/Throttle & Manifold`.
- `File Name` — The file name of the block diagram, for example, `sldemo_engine.mdl`.
- `Full File Name` — The full path and file name for the block diagram, for example, `\\matlab\toolbox\simulink\simdemos\automotive\sldemo_engine.mdl`.

When you enter a variable, the cell displays the type of content in brackets, `<>`, preceded by a percent sign, `%`. For example, if you add a `Page Number` variable, it appears as `%<page>`.

Note: Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints, instead of the actual page number.

Text

For `Text` content, type the text that you want to include in that cell (for example, the name of your organization). To type additional text on a new line, press the **Enter** key. When you are finished editing, click outside of the edit box.

You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.

To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the `text` command `String` property (in Text Properties).

Format Content in Cells

You can align cell contents using the left, center, and right alignment buttons. (Block diagrams are always center aligned.)

You can change font properties, such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

More About

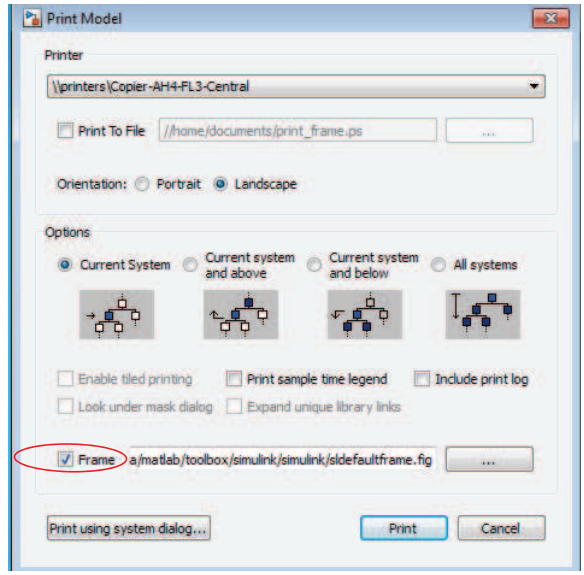
- “Print Frames” on page 66-2

Print Using Print Frames

To print using a print frame, you specify an existing print frame. If you want to build a print frame, see “Create a Print Frame” on page 66-6.

Note: If you enable the print frame option, then Simulink does not use tiled printing.

1. In the Simulink Editor or Stateflow Editor, select **File** > **Print** > **Print**.
2. In the Print Model dialog box, select the **Frame** check box.



3. Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the **...** button and select a print frame file you saved using the PrintFrame Editor. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
4. Specify other printing options in the Print Model dialog box.

Note: The paper orientation you specify with the PrintFrame Editor does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

5 Click **OK**.

The block diagram prints with the print frame that you specify.

Running Models on Target Hardware

About Run on Target Hardware Feature

- "Simulink Supported Hardware" on page 67-2
- "Tune and Monitor Models Running on Target Hardware" on page 67-3
- "Block Produces Zeros or Does Nothing in Simulation" on page 67-8

Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

Support Package	Vendor	Earliest Release Available	Last Release Available
Apple iOS Devices	Apple	R2015a	Current
Arduino Hardware	Arduino	R2012a	Current
BeagleBoard Hardware	BeagleBoard	R2012a	Current
LEGO MINDSTORMS NXT Hardware	LEGO	R2012a	Current
LEGO MINDSTORMS EV3 Hardware	LEGO	R2014a	Current
Raspberry Pi Hardware	Raspberry Pi	R2013a	Current
Samsung GALAXY Android Devices	Android	R2014a	Current

For a complete list of supported hardware, see Hardware Support.

Tune and Monitor Models Running on Target Hardware

In this section...
“Overview of Using External Mode” on page 67-3
“Run Your Simulink Model in External Mode” on page 67-4
“Stop External Mode” on page 67-5
“External Mode Control Panel” on page 67-5

Overview of Using External Mode

You can use External mode to tune parameters and monitor a model running on your target hardware.

External mode enables you to tune model parameters and evaluate the effects of different parameter values on model results in real time. Doing so helps you find the optimal values to achieve desired performance. This process is called *parameter tuning*.

External mode accelerates parameter tuning because you do not have to rerun the model each time you change parameters. You can also use External mode to develop and validate your model using the actual data and hardware for which it is designed. This software-hardware interaction is not available solely by simulating a model.

This workflow lists the tasks usually required to tune parameters with External mode:

1. In the model on your host computer, enable External mode.
2. (Optional) Place one or more sink blocks in your model. For example, use `Display` or `Scope` blocks to visualize data, or use a `To File` block to log signal data.
3. Give the Simulink software command to run the model on the target hardware.
4. (Optional) Observe the data External mode sends from the target hardware to sink blocks in the model on the host computer.
5. Change and apply parameter values in the model on your host computer.
6. Find the optimal parameter values by making adjustments and observing the results.
7. Save the new parameter values, disable External mode, and save the model.

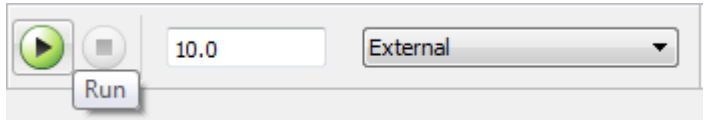
Run Your Simulink Model in External Mode

Note: If you have the Embedded Coder or Simulink Coder software, you can use External mode with a model that contains `Model` blocks (uses the "Model reference").

1. Connect the target hardware to your host computer.

   Different types of target hardware can use different types of connections. Check the External mode topic for your target hardware to determine which type of connection to use.

2. On the model toolbar, set **Simulation mode** to `External`.



3. Set the **Simulation stop time** parameter, located to the left of **Simulation mode** on the model toolbar. The default value is `10.0` seconds. To run the model for an indefinite period, enter `inf`.

4. Click the **Run** button.

   If your model does not contain a sink block, the MATLAB Command Window displays a warning message. For example:

```
Warning: No data has been selected for uploading.
> In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\+realtime\extModeAutoConnect.p>
extModeAutoConnect at 17
In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\sl_customization.p>myRunCallback at 149
```

   You can disregard this warning or add a sink block to the model.

   After several minutes, Simulink starts running your model on the board.

5. Change parameter values in the model on your host computer.

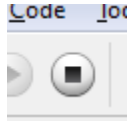
   Observe the corresponding changes in the model running on the hardware.

Any Simulink Sinks blocks in your model receive data from the hardware and display it on your host computer.

Note: External mode increases the processing burden of the model running on the board, and can cause overruns.

Stop External Mode

To stop the model running in External mode, click the black square Stop button located on the model toolbar, as shown here.



This action stops the process for the model running on the target hardware, and stops the model simulation running on your host computer.

If the **Simulation stop time** parameter is set to a specific number of seconds, External mode stops when that time elapses.

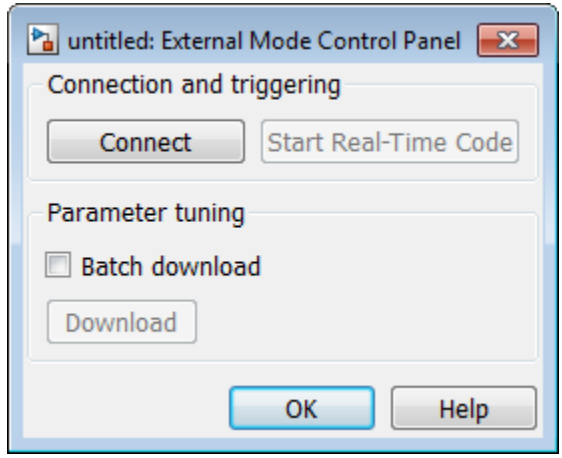
When you are finished using External mode, set **Simulation mode** back to `Normal`.

External Mode Control Panel

Using External Mode Control Panel provides additional control of External mode operations, including:

- Connect or disconnect the model on the host computer to/from the model running on the target hardware.
- Start and stop the model running on the target hardware.
- Gather changes to parameter values in a batch before applying them concurrently to the model running on the target hardware.

To open the External Mode Control Panel dialog box, in the model window, select **Code** > **External Mode Control Panel**.



The **Connect/Disconnect** button connects or disconnects the model on your host computer to/from the model running on the target hardware. If the model is not running on the target hardware, clicking **Connect** automatically deploys and runs the model on the target hardware.

- The **Start Real-Time Code/Stop Real-Time Code** button starts or stops the model running on the target hardware.
- **Batch download** enables you to gather changes before using the **Download** button to simultaneously apply those changes to the model running on the hardware:
  - While **Batch download** is disabled, clicking **OK** or **Apply** in a block dialog box sends updated block parameter values from the block to the model running on the target hardware.
  - When you enable **Batch download**, clicking **OK** or **Apply** in a block dialog box stores updated block parameter values on the host computer. You can complete a set of changes before clicking **Download** to simultaneously send all of the updated values to the model running on the target hardware. This feature is useful for avoiding error conditions when a model contains blocks whose parameter values must be changed concurrently.

External Mode Control Panel displays `Parameter changes pending...` to the right of the **Download** button until the model running on the target hardware has applied the new parameter values.

Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

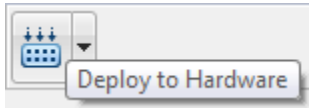
This is the expected behavior.

For example, in a model, if you select **Simulation** > **Mode** > **Normal** and then select **Simulation** > **Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, select **Tools** > **Run on Target Hardware** > **Prepare to Run**. Then, click the Deploy to Hardware button.



To use External mode, select **Simulation** > **Mode** > **External**. Then, select **Simulation** > **Run**.

- "Fast Restart Methodology" on page 68-11
- "Factors Affecting Fast Restart" on page 68-14

How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

1. Compiles the model
2. Simulates the model
3. Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and root inputs and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

- "Factors Affecting Fast Restart" on page 68-14

Fast Restart Workflow

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again.

1. Turn on fast restart using the **Fast restart** button on the Simulink Editor toolbar or from the command line.
2. Simulate the model. The first simulation requires the model to compile, initialize and save a `SimState`. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.
3. Perform any of these actions:

   - Change tunable parameters.
   - Tune root-level inputs.
   - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
   - Change inputs to `From File` and `From Workspace` blocks.

   Once you have initialized a model in fast restart, you cannot

   - Change the dimension, type, or complexity of a signal or variable.
   - Make changes to a nontunable parameter such as sample time.
   - Make structural changes such as adding or deleting blocks or connections.

   These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.
4. Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
5. Once you have achieved the desired response, turn off fast restart.

Note: When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

More About

- "How Fast Restart Improves Iterative Simulations" on page 68-2
- "Factors Affecting Fast Restart" on page 68-14
- "Save and Restore Simulation State as SimState" on page 23-37

Get Started with Fast Restart

In this section...
“Prepare a Model to Use Fast Restart” on page 68-6
“Enable Fast Restart” on page 68-6

Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `SimState`.
- The simulation mode is Normal or Accelerator mode.

Caution When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type

```
set_param(model,'FastRestart','on')
```

More About

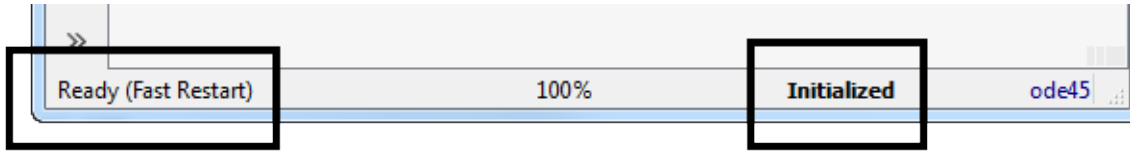
- "Fast Restart Methodology" on page 68-11
- "Factors Affecting Fast Restart" on page 68-14

Simulate a Model Using Fast Restart

After you load your model and turn on fast restart, simulate the model.

1. Simulate the model by calling `sim` or clicking the **Play** button in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `SimState`.

   Once the simulation is complete, the status bar shows that the model is initialized in fast restart.



2. Adjust tunable parameters in the model, such as the gain value of a `Gain` block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
3. Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
4. When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.
5. To keep your changes, save the model.

Note: After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

Stop Simulation and Exit Fast Restart

In this section...
“Stop a Simulation” on page 68-10 “Exit Fast Restart” on page 68-10

Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can now change tunable parameters in the model
- You can terminate the simulation and exit fast restart by clicking the **Fast restart** button off.

Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button off. To do this programmatically, type:

```
set_param(model,'FastRestart','off')
```

- Simulink terminates simulation.
- Simulink discards any compiled information about the model.
- The model must compile again the next time you simulate.

"Custom Code in the Initialize Function" on page 68-13

Simulation Modes

You can use fast restart in Normal and Accelerator simulation modes.

Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the **Simulation > Model Configuration Parameters** dialog box.
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the `IC` block
  - **Initial Output** parameter of the `Merge` block
  - **Data** parameter of the `From Workspace` block
  - **Signal** parameter and signal groups of the `Signal Builder` block.

Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

1. Call model `Start` method.
   a. Call `mdlStart` S-function method.

2 Call model `InitFcn` callback.

3 Call model `Initialize` method.

   a Call `mdlInitializeConditions` S-function method.

   Note: Use the ssIsFirstInitCond flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.

4 Call model and block `StartFcn` callbacks.

Note: Steps 1–4 apply to all simulations in Simulink (with or without fast restart).

5 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`SimState`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `mdlGetSimState` S-function method.

6 This is a standard execution phase of any simulation, with or without fast restart.

   - Call model `Outputs`.
   - Call model `Update`.
   - Call model `Derivatives`.
   - Repeat these steps in a loop until stop time or a stop is requested.

7 After simulation ends, call model and block `StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.

8 Restore the simulation snapshot taken for fast restart. As part of the restore, call `mdlSetSimState` S-function method.

9 Wait in a reinitialized state until one of these actions:

   - To run another simulation in fast restart, return to step 3 but skip step 5.
   - To terminate the simulation, call the model terminate method.

     a Call `mdlTerminate` S-function method.

     b Do not call `StopFcn` callbacks again at this point.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-70.

SimState and Initial State Values

You can change initial state values, including `SimState`, in between fast restart simulations.

When a `SimState` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `SimState` object. Thereafter, on the first step forward, Simulink checks to see if a `SimState` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `SimState` object.

Analyze Data Using the Simulation Data Inspector

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name **<modelname> fast restart run <number>**. The value of `number` increments for each simulation.

Custom Code in the Initialize Function

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

More About

- “Factors Affecting Fast Restart” on page 68-14
- “What Is a SimState?”

Factors Affecting Fast Restart

There are some limitations to simulating in fast restart.

- Fast restart does not support these modes:
  - Rapid Accelerator
  - External
- When a model is in the reinitialized state, you cannot:
  - Make structural changes.
  - Make changes to nontunable parameters such as sample time.
  - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support `SimState`. These blocks include:
  - SimEvents blocks
  - Simscape Multibody Link First Generation blocks
  - MATLAB function blocks that contain system objects
  - S-functions that do not implement SimState `get` and `set` methods but have `Pwork` vectors declared
  - `From Multimedia File`
  - `To Multimedia File`
  - `From Audio Device`
  - `To Audio Device`
  - `Multipath Rician Fading Channel`
  - `Multipath Rayleigh Fading Channel`
  - `Derepeat`
  - `DC Blocker`
  - `Stack`
  - `Queue`
  - `Read Binary File`
  - `Write Binary File`

  - `Video Viewer`
  - `Frame Rate Display`
  - `Video From Workspace`
  - `Video To Workspace`
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- When you use fast restart for model references in Accelerator mode, you cannot tune block parameters.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.
- When there are multiple model references to the same submodel, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart is not compatible with these tools:
  - Simulink Profiler
  - Simulink Debugger
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.
